The *Naufragios* ("Shipwrecks") of Cabeza de Vaca, which relate to the Florida expedition and his journey to the city of Mexico, appeared at Zamora in 1542; the work has frequently been reprinted, and an annotated English translation was published by T. Buckingham Smith in 1851. His *Comentarios* (1555) chronicle the events of the South American expedition. *See* Fanny Bandelier, *Journey of A. Nuñez Cabeza de Vaca* (ed. A. F. Bandelier, New York, 1905).

NUÑEZ DE ARCE, GASPAR (1834–1903), Spanish poet, dramatist and statesman. Deputy for Valladolid in 1865, he was imprisoned at Cáceres for his violent attacks on the reactionary ministry of Narvaez, acted as secretary to the revolutionary Junta of Catalonia, and wrote the "Manifesto to the Nation" (Oct. 26, 1868). He served under Sagasta as minister for the colonies, the interior, the exchequer and education; but ill-health compelled him to resign in 1890.

Nuñez de Arce first came into notice as a dramatist with such plays as *La Cuenta del Zapatero* (1859), and *El haz de leña* (1872). But his talent was more lyrical than dramatic, and his celebrity dates from the appearance of *Gritos del combate* (1875), a collection of poems exhorting Spaniards to save the country from anarchy and lay aside domestic controversies. He was maintained in popular esteem as the only possible rival of Campoamor by a series of philosophic, elegiac and symbolic poems: *Raimundo Lulio*, *Ultima lamentación de Lord Byron* (1879), *Un Idilio y una Elegía* (1879), *La Selva oscura* (1879) and *La Visión de Fray Martín* (1880). The old brilliance sets off the naturalistic observa-

SCENES OF INTEREST IN THE OLD CITY OF NÜRNBERG

1. The old fortress castle, on the north side of the city
2. Aerial view of Nürnberg looking down on Castle hill (centre, left) and its mediaeval fortifications around which the town developed. At the left is the imperial castle, and in the centre the Vestner-Turn (round tower), built 1561. Behind it in a diagonal line is the Five-Cornered tower, in which was the torture device known as the "Iron Maiden"
3. Looking across the roofs of Nürnberg to Castle hill. St. Sebald's church (1230–73), with twin towers, is on the left
4. House (centre) of Albrecht Dürer. It has been owned by the city since 1826, and has been restored
5. Detail of an old house on Adolf Hitler Platz, with characteristic gable
6. The Luitpold arena during a nazi party congress prior to World War II

tion of *La Pesca* (1884) and *La Maruja* (1886). The list of his works is completed by *Poemas cortos* (1895) and *¡Sursum corda!* (1900); *Hernán el lobo*, published in *El Liberal* (Jan. 23, 1881), and *Luzbel* remain unfinished. Gracious in his vision, sincere and patriotic, his weakness was sentiment and rhetorical sympathies. (J. F.-K.)

NÜRNBERG [NUREMBERG], second town in Bavaria, Germany, in size, and first in commercial importance. It lies in the district of Middle Franconia in a sandy, well-cultivated plain, 124 mi. by rail N.N.W. from Munich. The city stands on the Pegnitz, which is here crossed by 14 bridges.

History.—The first authentic mention of the town of Nürnberg, which seems to have been called into existence by the foundation of the castle, occurs in a document of 1050; and about the same period it received from the emperor Henry III permission to establish a mint and a market. It is said to have been destroyed by the emperor Henry V. in 1105, but in 1127 the emperor Lothair took it from the duke of Swabia and assigned it to the duke of Bavaria. An imperial officer, styled the burggrave of Nürnberg, became prominent in the 12th century. This office came into the hands of the counts of Hohenzollern at the beginning of the 13th century. The town was ruled by patrician families. German monarchs frequently resided and held diets here, and in 1219 Frederick II. conferred upon it the rights of a free imperial town.

Like Augsburg, Nürnberg attained great wealth as an intermediary between Italy and the East on the one hand, and northern Europe on the other. Its manufactures were well known. The town gradually extended its sway over a territory nearly 500 sq.mi. in extent, and was able to furnish the emperor Maximilian with a contingent of 6,000 troops. But perhaps the great glory of Nürnberg lies in its claim to be the principal fount of German art. Adam Krafft, Veit Stoss and Peter Vischer are famed as sculptors. In painting Nürnberg claims Wohlgemuth and Dürer. A large proportion of the old German furniture, silver-plate and stoves was made in Nürnberg workshops. Its place in literary history it owes to Hans Sachs and the other meistersänger.

Nürnberg was the first imperial town to embrace Protestantism (about 1525). The first blow to its prosperity was the discovery of the sea-route to India in 1497; and the second was inflicted by the Thirty Years' War, during which Gustavus Adolphus was besieged here for ten weeks by Wallenstein. The downfall of the town was accelerated by the illiberal policy of its patrician rulers. In 1803 Nürnberg was allowed to maintain its nominal position as a free city, but in 1806 it was annexed to Bavaria.

After 1933 Hitler's National Socialist party held its annual September convention at Nürnberg with great displays of fervent oratory and parades of troops, Hitler Youth and other nazi organizations. Here were decreed in 1935 the "Nürnberg laws" which divided the people of Germany into three classes: (1) German (Aryan) citizens enjoying full rights; (2) Jews, who had two or more Jewish grandparents and who were excluded from the ordinary rights of citizenship, could not marry Germans and were virtually condemned to a ghetto existence; and (3) "mixed" or "hybrid" persons, who had one or two Jewish grandparents, were not of Jewish faith or married to a Jew, and who might marry Germans and become assimilated into the German people. For the party conventions Hitler began the construction of a gigantic stadium, to be the largest in the world, in the Zeppelin field near Nürnberg.

During World War II several severe British air raids destroyed or damaged many of Nürnberg's famous buildings, including the Dürer house.

Population and Industries.—The population of Nürnberg was, in (1939) 430,851, more than two-thirds of whom are Protestant. The city is a garrison town. The manufactures are toys and fancy articles in metal, carved wood and ivory, which are collectively known as Nürnberg wares. It is also famous for pencils, needles, electric apparatus, chromo-lithography and motors. Nürnberg is ordinarily the chief market in Europe for hops. It is an important junction for railways and is served by the Ludwig canal, connecting the Danube and the Main.

Buildings.—Considerable sections of the ancient walls and moat still remain; of the 365 bastions which formerly strengthened the walls, nearly 100 are still *in situ*, and a few of the old gateways have also been preserved. Most of the streets are narrow and crooked, and the majority of the houses have their gables turned towards the street. The general type of architecture is Gothic, but the rich details, which are lavished with especial freedom in the interior courts, are usually borrowed from the Renaissance. Most of the private dwellings date from the 16th century, and there are practically none of earlier date than the 15th century. The roofs are of red tile.

The old castle (Kaiserschloss), on a rock on the north side of the town, dates from the early 11th century, but received its present form about 150 years later. It was restored in 1854–56.

Nürnberg contains several churches, the finest of which are those of St. Lorenz, of St. Sebald and of Our Lady. All three are Gothic edifices and are notable for their elaborately carved doorways, in which free play has been given to the exuberant fancy of the Gothic style. The church of St. Lorenz, the largest of the three, was built in the 13th and 14th centuries and has recently been restored. In it is the masterpiece of the sculptor, Adam Krafft, consisting of a ciborium, or receptacle for the host, in the form of a florid Gothic spire 65 ft. high; the carving of this work is exquisitely minute and delicate. The shrine of St. Sebald, consisting of a bronze sarcophagus and canopy, in the richest Gothic style, adorned with numerous statues and reliefs, is looked upon as one of the greatest achievements of German art. It was executed by Peter Vischer, the celebrated artist, in bronze, who was occupied on the work for 13 years (1506–19). The church of Our Lady has some fine old stained-glass windows and paintings by Michael Wohlgemuth. The Tuchersche altar, with its winged picture, is one of the finest works of the Nürnberg school about the middle of the 15th century.

The town hall (Rathaus), erected in the Italian style in 1616–19, contains frescoes by Dürer, and a curious stucco relief of a tournament held at Nürnberg in 1446. The building incorporated an older one of the 14th century, of which the great hall, with its timber roof, is part. The most interesting secular buildings are the houses of the old patrician families. A special interest attaches to the dwellings of Albert Dürer and Hans Sachs, the cobbler-poet. The streets are embellished with several fountains, the most noteworthy of which are the Schöne Brunnen, 1385–96, in the form of a large Gothic pyramid, adorned with statues, and the Gänsemännchen or goose-mannikin.

The Germanic national museum, established in an old Carthusian monastery includes masterpieces by Holbein, Dürer, Wohlgemuth and others. The municipal library contains many thousands of manuscripts and books, some of which are of great rarity.

NURSERIES, NURSERY TREES: *see* ARBORICULTURE.

NURSERY EQUIPMENT. A baby should room alone, if possible, and must always sleep alone. Nursery equipment should be simple and all furniture and fittings of a type that may be readily washed. Painted walls are preferable but fresh clean wall paper is permissible. The best floors are well oiled or waxed hard wood or linoleum with a few small, washable, cotton rugs. Muslin curtains and dark window shades permit of good ventilation and subdued lighting. The necessary furniture consists of: A table of plain wood about two by three feet in size and low enough so that the mother may reach anything on it from her chair. Two low chairs without arms; one may be a rocker. A screen with removable washable panels to be used for protection from draughts and as a rack for airing the clothing. Two accessible shelves on the wall for the toilet articles. A closet with shelves or a bureau to hold the clothing. A wall thermometer and a covered pail to hold soiled diapers.

The Bed.—A crib or bassinet may be used. The latter is advised for the first two months; the best kind is the ordinary clothes basket with handles at either end. This affords free ventilation, is easily cleaned, may be placed upon two chairs or a bench and is moved about readily. For a mattress an ordinary hair pillow

is best; a feather pillow must not be used but one of felt or kapoc is a good substitute. Large pillow cases are preferable to sheets; one to hold the mattress and so serve as a lower sheet; the other to hold the blankets and serve as an upper sheet and bed spread. A small blanket rolled tightly may be placed at the foot of the bed before the upper sheet and blankets are tucked in; this will hold the upper bedding away from the baby's feet and permit free movement of the legs. A pillow for the head is not needed.

Care of the Nursery.—The bed should be placed in a corner of the room well protected from a direct draught and too strong a light. The wall thermometer should be placed on the wall above the head of the bed. The temperature of the nursery should not be above 68° F nor below 66° during the daytime. For the first three months the proper night temperature is from 62 to 64° and later this may be reduced to from 50 to 54 degrees. In winter the proper ventilation may be secured by the use of a window board and in summer the windows, thoroughly screened, may be left open during the cooler part of the day and at night. The room should be well cleaned and aired every day and the baby in his basket taken out of the room while this is done. Soap and hot water with sunshine are the best cleaners and disinfectants to use.

The Bath.—Tub baths may be given as soon as the umbilical cord drops off, usually about the tenth day after birth. Until that time sponge baths only are permitted. The equipment needed for the bath consists of: A portable bathtub of rubber or enamel ware. Rubber apron for the mother. Small soft blanket. Supply of soft and absorbent towels. Two wash cloths; one for the face and head and the other for the body. A tray holding a cake of castile or other pure white soap, a tube or jar of baby cream, plain unscented talcum powder, a few covered glass jars to hold small squares of sterile gauze, cotton pledgets and liquids needed, safety pins of assorted sizes, a bottle of boric acid solution and a bath thermometer. These articles should be replaced on the tray after use and covered with a clean towel until needed again. When all the equipment is in place, undress the baby and lay him on the bed wrapped in the soft blanket. Put on the rubber apron and pour the water into the tub. The temperature of the water must be tested with the bath thermometer at the last moment before the bath is given. For the first few weeks this should be 100° F. From the second to the sixth month the right temperature is 98 degrees. For the remainder of the first year, 95° is proper. During the second year the temperature of the bath water may be lowered to from 85 to 90° F. When the water is at the right temperature, take the baby in your lap and place the towel about him in place of the blanket. Before placing the baby in the tub use one of the wash cloths to bathe his face with plain water. Then soap the cloth well and gently wash the head, neck and back of the ears. Be careful not to get any of the soap in the baby's eyes. Rinse the wash cloth and wash off the soap from the head and neck. Now lift the baby by placing your right hand and arm under his buttocks and your left arm under his back with the forearm supporting his head. Set him gently in the tub keeping his back and head well supported, leaving your right arm and hand free for giving the bath. Soap the second wash cloth and rub the body, arms and legs all over, gently but thoroughly. Then rinse the cloth and wash off the soapy lather. The bath should not take more than a few moments during the first few weeks, later it may be given more leisurely. Now lift the baby from the tub and wrap him in the bath towel on your lap. The drying process consists of a series of gentle pattings; do not irritate the baby's delicate skin by rubbing. The head and face should be dried first and then the arms, legs and body. Do not wash out the baby's mouth, ears or nostrils unless so advised by your doctor. If the eyes need special care they may be wiped gently with a pledget of sterile cotton wet with sterile water or boric acid solution. When this is done, the baby should be turned on his right side while the right eye is washed and on the left side for the left eye; this turning is necessary to prevent the solution used for one eye from running into the other eye. After the baby is well dried it is a good plan to smear all of the folds of the skin in the groin, under the arms and about the neck with a little of the baby cream or with olive oil. Then comes a light dusting of the body with talcum powder and the baby is ready for his clothing, his feeding and his nap. Diapers must be changed as soon as soiled, placed in a pailful of cold water and once each day thoroughly scrubbed with soap and hot water, rinsed in hot water and then boiled for five minutes. If possible, dry the diapers in the sunlight.

Clothing.—Three points to remember about the baby's clothing are that it must be loose, light in weight and of materials that will not irritate the skin. The same weight clothing should be worn indoors both summer and winter. On very hot days the shirt, diaper and dress are sufficient. In cold weather, a light weight knitted shawl or blanket may be used for added warmth. For out of doors in cold weather, a warm cloak, hood and bootees are necessary. Socks may be worn if needed for warmth but their use is rarely desirable except in very cold weather. (*See* INFANCY.)

NURSERY SCHOOLS. The nursery school is a comparatively modern section of education designed to provide a suitable environment for the education and physical development of children aged from two to five years.

Great Britain.—The age of compulsory school attendance is five years, but education authorities may admit children at three years and in the 19th century frequently did so in urban areas in England (in Scotland there was no general demand for the admission of children under five).

By the beginning of the 20th century conditions essential to right development of young children were more fully understood, and doctors and educationists alike attacked the prevailing school education of the "under fives" in crowded classrooms, deprived of fresh air and exercise and subjected to formal instruction.

In 1908, because of an adverse report made by five women inspectors, the board of education appointed a consultative committee to report on school attendance of children below the age of five. The committee's report (Cmd. 4,259; H.M.S.O., London) recommended that children under five should remain at home but that those from homes in which their mental and physical development could not be properly secured should be sent to places specially intended for their training, the best place for this purpose being a nursery school, providing air and sunshine, open space, hygienic structures, opportunity for physical activity, for forming good habits and for sleep, and education on kindergarten lines by enlightened teachers. The board took no action, however, to establish such schools, and local authorities increasingly excluded the "under fives."

Voluntary effort had already opened day nurseries for "under threes" and a few free kindergartens on Froebelian lines for children from two to five years of age. Nursery schools on these lines, though small in number, became centres of light and healing in slum areas. The majority were held in adapted houses, with small gardens, but all sought to provide conditions for healthy development of body and mind; formal lessons were replaced by training of the senses and of speech and movement; independence and self-control were encouraged; happy activity and comradeship in a friendly community fostered social virtues. Meetings were held for parents, so that methods of child care became more widely understood in the community. Co-operation was established with infant-welfare clinics and public medical services. In 1914 a notable advance was made by Rachel and Margaret Macmillan, who in a riverside slum area in Deptford, London, established a large open-air nursery school.

In 1918 the president of the board of education, H. A. L. Fisher, included in his Education act regulations giving local authorities power to supply or aid nursery schools or nursery classes for children from two to five years of age. Economy nipped the new growth. Few new schools were established, but grants helped to maintain those in existence. Nursery classes for children aged

from three to five, in infant schools, however, increased and were influenced by nursery school principles.

During the interval between 1918 and the Education act of 1944, nursery schools increased in numbers and developed fresh principles and methods. "Didactic apparatus" gave way to more spontaneous play. Greater flexibility of procedure to suit individual needs replaced formal techniques of physical care and habit training. Increased psychological studies and especially the work of Susan Isaacs, emphasizing the far-reaching influence of early childhood, changed not only the methods but also the conception of the nursery school as being solely designed to compensate for imperfect homes; nursery schools are now recognized as a valuable extension of the good home, providing an environment where, during the busy hours of the mother's day, small children may receive education suited to their needs.

The care of children for long hours when mothers go out to work has passed, in many areas, to day nurseries organized by the ministry of health. After World War II when many wartime nurseries were established, the principle of educating, as well as caring for the child, spread to the day nurseries. The Education act of 1944 made it the duty of local education authorities to provide nursery schools wherever there was a need, but progress was again checked by national economy. In 1953 there were 473 nursery schools in England and Wales and 71 in Scotland (excluding private nursery schools); and nursery classes numbered 1,965 in England and Wales and 133 in Scotland.

Other European Countries.—Institutions analogous to nursery schools are to be found on the continent of Europe. In France they are called *écoles maternelles;* in Belgium *écoles gardiennes* or *jardins d'enfants;* in Austria and in the Scandinavian countries *Kindergarten;* and in Germany and in Switzerland *Kindergarten, Krippen* and *Kleinkinderbewahranstalten.*

See L. de Lissa, *Life in the Nursery School and in Early Babyhood* (New York, London, 1949); D. E. M. Gardner, *Education Under Eight* (London, 1949). (E. St.; D. E. M. G.)

United States.—Research in biological and social sciences and conclusions from clinical medicine and psychiatry emphasize the importance of the years immediately following infancy. At that time every person, for reasons of his own bodily structure and the nature of the social world into which he is born, faces two major adjustments: he needs to depend less upon others and he discovers a confusing world of persons, objects and their activities which he must try to understand and with which he must live. His personality results from the interaction of these organically and environmentally determined forces. By his fifth or sixth year the child has acquired the attitudes and behaviour, that is, the individuality which will thereafter identify and support him. The best guidance during this period in which he is most rapidly growing physically and acquiring social, intellectual, language and motor skills is not a simple matter of universally providing certain situations or certain techniques. It is, rather, an interweaving process in which, knowing each child's development, opportunities to learn are skilfully timed. For children $2\frac{1}{2}$ to 5 years old, the nursery school (or preschool) provides such guidance. Its professional standards, emphasizing specifically trained teachers, are based on a philosophy which includes the child's parents as active participants.

Early nursery schools (Bureau of Educational Experiments, New York, 1919, University of Iowa, Iowa City, 1921, Merrill-Palmer school, Detroit, 1922) were established to study young children and to provide observation and training opportunities for parents and teachers. Subsequent development, including widespread use of similar facilities in universities, colleges and high schools, extended the professional training function to family service related fields such as medicine and social work. However, many groups operate solely for the benefit of the children and families involved. Between 1933 and 1945 two federally supported programs in connection with public education furthered the understanding and acceptance of this educational institution. A 1951 survey listed 3,377 preschools under governmental, private, religious and secular sponsorships. Co-operative nursery schools, parent-initiated, financed and administered, employ trained teachers to ensure standards.

Programs for training teachers emphasize studying this particular age and understanding personality development; they require supervised participation in work with children and their parents.

It is accepted that the nursery school was not designed as a home substitute but that the child's potentialities can be more completely realized as the school works with him and his parents; it is a desirable supplement. The incompletely functioning home may receive substitutive services in the school; this is not its purpose, however. All organizers of groups for young children must recognize the educational implications and, therefore, responsibilities; allied professional workers and parents must demand more than promotion of physical safety, health and entertainment.

Although such essentials as attractive, clean rooms, sanitary facilities, protected outdoor space and maximum child-teacher ratio (1 to 8) are easily described, the subtler, less tangible attributes of any school are more critically discriminating. The clinical and scientific knowledge of the teachers and their personalities are the significant mediating instruments which, with suitable equipment for play, make for a child a constructive group, individually dimensioned.

The educational program for preschool children presupposes participation in play and real-life situations as basic experience within which the child develops. He needs space for being vigorous, being awkward, being alone, being part of an active group, for his happiness and for his concerns. He needs materials appropriate to his skills, his size, his ideas, his feelings, and he needs an understanding teacher to help him help himself explore verbally and manually and learn from both people and things. He needs children and adults outside his family, for as he rubs elbows with them, disagrees with them, shares with them and sometimes ignores them, he learns not to be threatened by them or to exploit them or to follow them blindly but instead achieves constructive attitudes for living with others.

NURSING. Because of basic differences in eastern and western cultures, the evolution of nursing has been extremely uneven. Historically it may be said to fall into five fairly well-defined periods. These are (1) pre-Nightingale; (2) the pioneer Nightingale period 1860–1900; (3) the period of professional self-development 1900–20; (4) the period of rising internationalism between the two World Wars; and (5) nursing in the Atomic Age.

To 1860.—From the time of Phoebe (A.D. 60), nursing has been recognized as one of the works of mercy of the Christian church. With the rise of monasticism, the care of the sick became a function of many religious orders. It was one of the services performed by communities organized under the rule laid down by St. Benedict in the 6th century. The mother house, an organizational pattern developed by the orders, was adopted by later Catholic and Protestant nursing orders and, in parts of Europe, by the Red Cross. Among the earliest nursing records are those of the Hôtel-Dieu, Paris (A.D. 606), where, since the 12th century, Augustinian sisters have been in charge. From the military nursing orders, such as the Knights Hospitaller of St. John of Jerusalem, nursing inherited a tradition of rigorous discipline. A trend toward the modernization of nursing began when Mlle. de Gras (Louise de Marillac) took a vow in 1634 to work under the direction of St. Vincent de Paul. The principles he laid down for the guidance of the Sisters of Charity, now one of the largest and most widely distributed nursing orders in the world, had lasting influence. Pastor Theodor Fliedner and his wife, whose work influenced the later development of nursing, laid the foundations of the modern deaconess movement at Kaiserswerth, Ger., in 1836. The Sisters of Mercy and the Sisters of Charity, established in Ireland at about the same time, began the reform of nursing in that

country. The Reformation left England without a system of hospital nursing. Nursing, therefore, had no distinctive part in the colonial development of the United States.

Hospitals built by the Spaniards in Latin America antedated public hospitals in the United States by about 300 years. Publication in France of the Jesuit "Relations," the reports of missionaries to "New France," aroused interest in the needs of Canada's colonists. Augustinian Hospitallers from Dieppe, the first nursing sisters to cross the Atlantic, established the Hôtel-Dieu, Quebec, in 1639. Jeanne Mance (1606–73), the first white woman to arrive at Montreal, there established the Hôtel-Dieu (1664) and secured the assistance of the Sisters of St. Joseph—the Hospitallers of La Fleche—while herself remaining outside the order. Visiting nursing was introduced into Canada by Mme. d'Youville, who organized the Soeurs Grises or Grey nuns of Montreal (1755). Charity hospital in New Orleans was staffed by Ursuline sisters from 1737 until Louisiana became part of the U.S. Beginning in 1834, Sisters of Charity conducted the nursing service.

The earliest indigenous order in the U.S. was organized by Elizabeth Ann Seton in 1809 and incorporated in 1917 as the Sisters of Charity of St. Vincent de Paul. These sisters undertook hospital nursing at the Baltimore infirmary (later University of Maryland hospital) in 1923. By 1870, 17 sisterhoods and the Alexian brothers were providing the nursing service in 70 Catholic hospitals.

Four German deaconesses (Lutheran) arrived in Pittsburgh in 1849. By 1880, mother houses under Lutheran, Evangelical and Methodist auspices had been established in Philadelphia, Pittsburgh, Chicago, Milwaukee and other middlewestern cities. Anglican sisterhoods, similar to the new orders in England, provided nursing service for St. Luke's hospital, New York city (1858); St. Mary's Free Hospital for Children, also in New York (1870); and the Children's hospital, Boston, Mass. (1871).

Florence Nightingale.—Miss Nightingale made outstanding contributions to the fields of sanitation, statistics, military medicine and hospital administration but is most widely known as the founder of modern nursing. Born to luxury but dissatisfied with a life of leisure, she was endowed with the intelligence of a scientist and the emotional drive of a reformer. She observed and studied nursing as practised by the Augustinians and numerous other orders. She spent three months with the Fliedners at Kaiserswerth where she found the spirit more impressive than the practice of nursing. Convinced of the need for reform in nursing, she had just opened an institution for the care of the sick in London when, in 1854, England's secretary at war asked her to undertake the nursing of soldiers in the Crimea. The staff she recruited was made up of Catholic and Anglican sisters and practical or "experienced" nurses. The effect of her energetic and well-directed attack on the shocking results of disinterest and military red tape was spectacular. The death rate dropped from more than 400 to 22 per 1,000. The fame of that achievement spread throughout the civilized world.

Miss Nightingale used the fund raised by popular subscription in her honour to establish and endow a school of nursing at St. Thomas' hospital in London. With the admission of 15 probationers, June 15, 1860, the modern era in nursing was begun. The primary characteristics of what came to be known as the Nightingale system of nursing education, although never adopted in its entirety by any country, were (1) a qualified nurse in command of the school; (2) a planned course of instruction; (3) careful selection of students; (4) a home for students with provision for recreational and cultural activities; (5) access to the wards of a well-organized hospital where students could be given direct instruction in the care of patients; and (6) funds for the educational program. The aims of the Nightingale school were to train (1) hospital nurses; (2) nurses (instructors) to train others; and (3) nurses to care for the sick poor (visiting nursing). A supplementary period of three months was required for the third objective. Miss Nightingale insisted that health nursing is as important as sick nursing and incorporated her ideas about hygiene in her widely read *Notes on Nursing*. The new profession (Miss Nightingale preferred the term "calling") was rooted in Christian ideals and imbued with a crusading spirit. It inherited the traditions of military discipline and mother house subservience. It opened a door to opportunity for educated women.

By the latter part of the 19th century the general principles laid down by Miss Nightingale had been adopted by schools connected with both voluntary and tax-supported hospitals in the English-speaking countries and were having some influence in continental Europe. The demonstrable value to hospitals of nursing service by students plus lack of endowments for the schools led to a type of apprenticeship which prepared nurses for institutional service but seriously limited their preparation for community services. Graduates of pioneer schools in the British empire and the U.S. began at an early date to establish mission schools in China, Japan and India and, a little later, in the middle east. The deaconess movement gained momentum in northern and central Europe and the mother-house idea was also adopted by Red Cross nursing schools, especially in Sweden, Germany and Austria. District nursing, the pioneer type of public health nursing by lay nurses, was inaugurated in England in 1859. In 1875, the Metropolitan and National Nursing association in London established the principle, later adopted and expanded in the U.S., that district nurses should have hospital training followed by special experience under supervision. Midwifery was developed as a separate service for which nurses might, or might not, prepare. In the U.S. two hospitals which were established for the primary purpose of providing facilities for the practice of medicine by women physicians set up courses for nurses in 1869 and 1872 at the Women's hospital in Philadelphia, Pa., and the New England Hospital for Women and Children in Boston. The first "Nightingale" school of nursing in the U.S. was established, with advice from Miss Nightingale, at Bellevue hospital, New York city, in May 1873. By the end of that year two other schools which were destined to become famous had been established at the Massachusetts General hospital in Boston and in New Haven, Conn., and Dr. Mack's school at St. Catherines, Ont., had engaged three graduate nurses from England. The schools brought order out of the chaotic and debasing conditions surrounding hospitalized patients. The first schools under religious auspices were established in the mid-1880s; the earliest visiting nurse associations were organized in the same decade.

By 1900, 422 schools with widely varying educational standards and resources had been established. Modern nursing was facilitating the advancement of surgery and a wave of hospital construction swept across the country. Many of them established schools for the sole purpose of securing student service for the care of patients.

Period of Self-organization, 1900–20.—The evolution of modern nursing can most readily be traced by following the history of the national nursing organizations. In its struggles to overcome inertia, antifeminism, political and other opposition, the nursing profession had developed a marked trend toward self-organization before the end of the 19th century. Leaders in this movement believed that legal standards of education and practice were needed for the dual purpose of protecting those in need of nursing care and those who endeavoured to secure adequate preparation for practice. When Mrs. Bedford Fenwick effected the establishment of the British Nurses association in 1887, a few alumnae associations had been established in the United States. Mrs. Fenwick became the founder of the International Council of Nurses (I.C.N.) in 1899 which antedated the international organization of other health professions by a quarter of a century. Nurses from Great Britain, Canada, the U.S., Australia, New Zealand, South Africa and Denmark, in all of which the Nightingale influence was at work, attended the preliminary conference.

Miss Nightingale opposed the movement for state registration believing it to be premature. As a result British nurses were divided and did not secure a nurse practice act until after World War I. But the movement quickly gained momentum in other countries. In North America two organizations composed of American and Canadian nurses had been organized before 1900. With the British association they provided a nucleus for the Inter-

national Council of Nurses. Later (1908) Canadian nurses formed their own association. The American Nurses' association (organized 1896) became the I.C.N.'s official affiliate in the U.S. The organizations of the Finnish (1896) and Danish (1899) nurses, which were to become notably efficient in elevating the standards of nursing in their respective countries, became influential members of the I.C.N. at a somewhat later date. The Australasian Nurses association (1899) for some years included the nurses of New Zealand who, in 1901, with remarkable farsightedness secured the first nurse practice act in the world and established a firm co-operative relationship with the national government. The official publications of the national organizations became effective instruments for promoting the development of nursing. The pioneers were the *British Journal of Nursing* (1887) and the *American Journal of Nursing* (1900).

The second nurse practice act was secured in Cuba (1902) when nurses from the U.S. had an extraordinary opportunity to modernize nursing under the military government following the Spanish-American War. In the U.S., four state legislatures passed such acts in 1903—North Carolina, New Jersey, New York and Virginia. When the U.S. entered World War I the initial task was virtually complete; 47 nurse practice acts were in effect.

Other early organizations which made notable contributions to the advancement of nursing in the U.S. were the National League of Nursing Education (N.L.N.E.; 1893) and the National Organization for Public Health Nursing (1912). In Great Britain the College of Nursing (after 1939 entitled to the prefix Royal), which was later established in London (1916), quickly became the dominant force in British nursing. In the U.S. the N.L.N.E. continued to work for the improvement of basic nursing education after it had persuaded Teachers college, Columbia university (1899) to undertake a program for the preparation of graduate nurses for teaching in schools of nursing. This famous division of nursing education began modestly with funds laboriously raised by the nursing organizations and an enrolment of two students. M. Adelaide Nutting, appointed to direct the expanding program in 1907, was the first nurse to hold professorial rank in any university. She retired in 1925. An endowment in 1909 ensured stability and adaptation of programs to changing social and health needs. From its earliest days the division was a Mecca for international leaders of nursing thought.

Nurses of the British empire became interested in postdiploma education at a later date. When the Royal College of Nursing, a membership organization, received its charter, its department of education was empowered to institute and conduct examinations in all branches of women's work conducive to the efficient conduct of the nursing profession and to grant certificates and diplomas to those who pass prescribed examinations. As in the U.S., the first courses offered were for the preparation of nurse teachers.

By 1912, in the U.S., Great Britain, New Zealand and a few other countries, visiting nurses, organized originally to give nursing care in homes, were participating in a variety of specialized health programs such as child welfare, tuberculosis and school nursing. The direction of nursing services by governmental health agencies was still in its infancy. In the U.S. the National Organization for Public Health Nursing (N.O.P.H.N.; 1912) was organized by members of the older organizations to provide standards of preparation and practice and consultative services in connection with the public health movement and the development of public health nursing services. The N.O.P.H.N. began at once to urge those responsible for the basic education of nurses to provide a sound foundation for all types of nursing and to establish the requirement of one year of collegiate postdiploma preparation for public health nursing.

Wars expedite the evolution of nursing. Military needs, by depleting civilian services, force adaptations. The evolution of military services follows a fairly definite pattern. In the U.S. hospital conditions during the American Civil War were quite as shocking as those encountered by Miss Nightingale in the Crimea. The appointment of Dorothea Dix as superintendent of nurses for the federal military establishment did little to ameliorate the situation. The army nurse corps (1902) was not organized until the Spanish-American War had again demonstrated need for a permanently organized service. The navy nurse corps was organized in 1908.

In Great Britain, Queen Alexandra's imperial military nursing service superseded less formally organized services after the South African War (1899–1901). The territorial army nursing service was organized in 1907. Members of these corps were commissioned in 1941. The officers of Queen Alexandra's royal naval nursing service (organized 1902) have relative rank. Canada, however, was the first country (1904) to make provision for commissions for nurses in military service. In the U.S., army nurses were granted relative rank after World War I; both army and navy nurses were given temporary commissions in World War II. In the military reorganization of 1947, members of both corps were permanently commissioned as were those of the new air force nurse corps organized in 1949. The chiefs of the army and air corps have the rank of colonel; the highest ranking navy nurse is a captain. Members of all three corps served in the Korean war, 1950–1953, as did nurses of Australia, Canada, Denmark, France, Great Britain, the Netherlands, Norway, Sweden and Thailand.

After World Wars I and II.—Relationships between the Red Cross and military nursing require explanation. The International Red Cross was organized, in accordance with the principles laid down by the Treaty of Geneva (1864), as a politically neutral agency which would provide needed voluntary services in time of war. The League of Red Cross Societies (L.O.R.C.S.; 1919) was an outcome of experience in meeting civilian needs during World War I. Both work through the national Red Cross societies.

The preparation of nonprofessional volunteers for nursing service in wartime was actively promoted by the older organization; and a few national Red Cross societies, especially those of Japan, Germany, Austria and Scandinavia, established nursing schools. The division of nursing of the L.O.R.C.S. was helpful in clarifying issues in relation to the preparation, assignment and interrelationship of professional nurses and of nonprofessional volunteers such as nurses' aides. It actively promoted the teaching, by professional nurses, of courses for nurses' aides and also in home nursing and related subjects for use by nonprofessionals in their own homes.

From 1909 to 1947 the relationship between the American Red Cross (A.R.C.) and professional nursing had no counterpart. The nursing service of the A.R.C., in addition to providing nurses for disaster service and for teaching home nursing and other courses, provided a reserve of "enrolled Red Cross nurses" for the army and navy nurse corps. It spearheaded the recruitment of the 25,000 nurses who entered military service in World War I and the 59,000 who served in World War II.

The health section of the League of Nations (1922), which gave powerful impetus to the development of health programs by national governments, had no division of nursing. But the Rockefeller foundation, through its international health program, was already promoting the organization of nursing schools which would graduate nurses equipped to participate in health programs. Its influence has been felt throughout the world. The earliest of the foundation-assisted schools were that of the Pekin Union Medical college, Pekin, China, and the Ana Nery school in Rio de Janeiro, Braz. (1922). In the U.S., the Yale school, established with foundation support in 1923 as an educational experiment, was subsequently endowed by it. The foundation sponsored and assisted with the organization of the first university school of nursing in Europe, established in connection with the University of Brussels, Belg. (1936). By mid-century it had sponsored or given developmental aid to schools in other European countries, in South America, the far east, South Asia and in the South Pacific. The A.R.C. followed up its work for civilians in Europe by sponsoring the organization of modern schools in Prague, Czech.; Posnan and Warsaw, Pol.; Sofia, Bulg.; and Constantinople, Turk.

The League of Red Cross Societies established a postdiploma program in public health nursing in connection with the College of Nursing (London) at Bedford college. The scope of the program had been broadened when, in 1934, the L.O.R.C.S., in co-operation with the International Council of Nursing (I.C.N.),

transferred its program to the jurisdiction of the newly organized Florence Nightingale International foundation as the nucleus of an educational memorial to the founder of modern nursing.

In countries where nursing was already well established, the period between World Wars I and II was characterized by continuous effort to adapt the basic preparation of nurses to changing social and health demands upon the profession. As a basis for action objective studies of nursing were made, under a variety of auspices, in the U.S., Canada and Great Britain. The first of them, *Nursing and Nursing Education in the United States* (1922), was followed by the experiment at Yale and the subsequent endowment of that school. Concurrently the Frances Payne Bolton school was endowed and established at Western Reserve university, Cleveland, O. The organization on a collegiate level and endowment of the Vanderbilt University school, Nashville, Tenn., followed a few years later. Reports from these schools stimulated interest in efforts to utilize the resources of institutions of higher education for the education of nurses. Other state universities began to accept responsibility for educating nurses as the University of Minnesota had been doing since 1909. The organization of the Association of Collegiate Schools of Nursing in 1932 accelerated this movement. Between 1928 and 1934 the Committee on the Grading of Nursing Schools issued a series of reports which encouraged the upgrading of many hospital schools and hastened the closing of feeble ones.

In Canada, the University of British Columbia, Vancouver, was the first (1919) in the British empire to offer a basic program leading to a degree. Other Canadian universities followed its example. The University of Toronto, Ont. (1933), developed a basic collegiate program which prepared nurses for positions in all types of nursing, including public health nursing. This program and the postgraduate offerings of the university attracted nurses from many countries. The *Survey of Nursing in Canada* (1932), sponsored by the national medical and nursing organizations, provided a well-balanced guide to further developments. In Great Britain the report of the Lancet Commission on Nursing (1932) revealed the sharp conflict which had arisen between those who clung to the methods of the past and those who were concerned with current problems and future needs. The report was the forerunner of more searching investigations sponsored by the College of Nursing and philanthropic and health agencies. As in the U.S. and Canada, the control of nursing schools by hospitals in the interest of their own, rather than community service, obscured the basic issue—the need for independence and financial support for nursing schools.

Internationally, the most important publication of the period was the *Educational Program for Schools of Nursing,* published in three languages by the I.C.N. and promptly adopted by the L.O.R.C.S.

In World War II every country which called on nurses for military service was confronted with the fundamental problems of equitable adjustment of nursing resources to military and civilian needs, and need to develop methods for augmenting the peacetime supply of nursing service. The problem was effectively handled in Great Britain where all types of nursing personnel were required to register. Data thus obtained provided a sound basis for the recruitment of student nurses, the distribution of graduate nurses and the provision of supplementary services. War accelerated action in relation to a need which was already apparent in many countries, *i.e.,* preparation of workers to supplement the services of professional nurses. In Great Britain legislation (1943) set standards for the preparation of assistant nurses and provided for a register of them. In the U.S. the preparation of practical nurses was retarded by uneven progress in securing state legislation.

In the U.S., one-fourth of all active professional nurses volunteered for military service. The profession resisted a proposed draft but the American Nurses' association later went on record as favouring a draft of nurses which would ensure a register of all nursing personnel should there again be massive military need for nursing service.

Prior to World War II, in countries where modern nursing had been longest established, national governments had shown little evidence of continuous interest in the preparation of nurses in relation to total national need. In the U.S. the Army School of Nursing (1919–1931) was organized and controlled by the military establishment. Social legislation in the '30s had made provision for the preparation of graduate nurses for public health nursing but nursing schools had never received governmental assistance.

With the beginning of World War II nursing leadership in the U.S. was delegated by the several national nursing organizations to a National Nursing Council for War Service which undertook the co-ordination of the programs of the voluntary agencies and provided liaison with the American Red Cross and the several federal agencies concerned with the supply of military and civilian nursing service. The council initiated a modest program of federal aid to nursing education for which congress appropriated $4,700,000 during the period 1941–43. The few thousand additional students enrolled in nursing schools fell far short of the growing need. Concurrently with the withdrawal of nurses for military service, civilian use of hospital facilities increased at a phenomenal rate, and industries also required unprecedented numbers of nurses. An extensive program of assistance was provided by the Nurse Practice act of 1943 under which the U.S. public health service (PHS) set up a department of nursing education to administer the U.S. cadet nurse corps (July 1, 1943). When enrolment was discontinued Oct. 15, 1945, 84.5% of the 139,000 students in the schools had received federal assistance, *i.e.,* they were members of the U.S. cadet nurse corps. In contrast, there had been only 87,500 students in all schools in 1941, the year before federal aid was made available. The cadet corps effectively met the wartime emergency. Its methods also contributed to the advancement of nursing education. Following the war the essentiality of nursing as a national resource was recognized by the appointment of Lucile Petry Leone, who had directed the corps program, as chief nurse officer of the PHS with the rank of assistant surgeon general (equivalent to army rank of brigadier general). A division of nursing resources was created which conducts and promotes research and disseminates information about nursing.

The termination of World War II brought no end to the demand for nurses, so swiftly did social forces already in action create new or expanded demands for nursing services. Among them were the continuing growth of various types of hospital and health insurance, the adaptation of nursing to rapid changes in medical practice due to chemotherapy, advances in surgical procedure, anaesthesia and the like and to the broadening functions of medicine, especially in relation to prevention, rehabilitation and psychiatry, and the expansion of national health programs. The World Health organization became a stimulating and co-ordinating agency.

In the U.S. the Hospital Construction and Survey act (1947) set in motion a program which is rapidly expanding the capacity of hospitals and health centres but there is no federal program which helps to finance the preparation of the additional nurses and other personnel required by these facilities.

Publication of *Nursing for the Future,* the report of a study it had sponsored to facilitate the postwar adjustment of nursing, terminated the program of the National Nursing council. Out of a study of the structure and functions of the national nursing organizations, emerged in 1952 the new National League for Nursing (N.L.N.) and an expanded American Nurses' association (A.N.A.). The N.L.N., which superseded the National League of Nursing Education, National Organization for Public Health Nursing, and Association of Collegiate Schools of Nursing, set up an accreditation program as recommended by the study of nursing education. In Great Britain the passage of the National Health Service act (1946) was followed by a comprehensive nationally sponsored study of recruitment in preparation for nursing. The recommendations, directed toward improving the conditions which were causing serious "wastage" of students during training, were similar to policies generally accepted in the U.S. and Canada. Chief among them was recognition of student nurses as enrollees in schools as distinguished from service personnel. The study was followed by a

job analysis (1953). An earlier study had called attention to the preparation of nurses, including midwifery training, for work in the colonies.

Need for experimentation and studies of nursing functions, in order that the services of professionally prepared personnel be utilized at the highest level of efficiency, was everywhere apparent. The Canadian Nurses association courageously led off with a major research project. With financial support from the Canadian Red Cross, it set up an experimental school which attracted international attention and stimulated further experimentation in Canada. In a period of sharp competition for the services of young women it was believed that shortening the basic period of education would tend to attract larger numbers of desirable candidates to nursing schools. At the end of the four-year experiment it was concluded that when a school has complete control of students' time, nurses can be prepared at least as well in two years as in three (the 50-year-old standard) but their education must be paid for in money and not in service.

Number of Active Graduate Nurses per 100,000 Population, Selected Years (U.S.A.) 1900–51

Year	Number of active graduate nurses	Population (thousands)	Graduate nurses per 100,000 population
1900	11,804	76,094	16
1910	82,327	92,407	89
1920	103,878	106,466	98
1930	214,292	123,077	174
1940	284,159	131,936	215
1951	366,134	154,360	237

In the U.S. individuals and both official and voluntary agencies were increasingly interested in research. The A.N.A. in 1950 set up a five-year research program in the functions of nursing and a clearing bureau by means of which work in progress might be co-ordinated.

The World Health organization became the directing and co-ordinating agency in the health field. Missionary groups had been at work constructively in some of the underdeveloped areas for generations. By 1950 Catholic and Protestant groups had each established more than 1,100 hospitals and at least double that number of dispensaries. The total number of nurses employed by these agencies is not known. Emphasis by both groups has usually been on remedial therapy.

In addition to participation in W.H.O. programs, U.S. nurses were also assigned to the health missions included in the programs of the Technical Cooperation administration (Point Four) and the Mutual Security agency of the U.S. Nurses were sent to such countries as Iran, Thailand, Burma and Lebanon.

NUSKU, personification of the new moon, the name of the light and fire god in Sumer, Babylonia and Assyria, who is hardly to be distinguished from a god Gibil. Nusku-Gibil is the symbol of the heavenly as well as of the terrestrial fire. As the former he is the son of Anu, the god of heaven, but he is likewise associated with Enlil of Nippur, the earth god, and regarded as his messenger. A centre of his cult in Assyria was in Harran, where, because of the predominating character of the moon cult, he is viewed as the son of the moon god Sin (*q.v.*). He is often called upon to cleanse the sick and suffering in the magic fire rituals.

The fire god is also viewed as the patron of the arts and the god of civilization in general, because of the natural association of all human progress with the discovery and use of fire, and as the protector of the family. He becomes the mediator between humanity and the gods, since it is through the fire on the altar that the offering is brought into the presence of the gods.

While temples and sanctuaries to Nusku-Gibil are found in Babylonia and Assyria, he is worshipped more in symbolism than the other gods. Nusku and Gibil are symbolized by the lamp.

NUT, a term applied to that class of fruit which consists generally of a single kernel enclosed in a hard shell. Botanically speaking, nuts are one-celled fruits with hardened endocarps, sometimes enveloped in a cupule or cup, formed by the aggregation of bracts as in the hazel and acorn. A great number of nuts enter commerce for various purposes, principally as articles of food or sources of oil and for several ornamental and otherwise useful purposes. Certain of the edible species such as pecan, hickorynut, Brazilnut, sapucaianut, butternut, Persian walnut, coconut, pistachionut, and others are especially rich in fat, while such others as the lychee, chestnut, chufanut and the waterchestnut are notably rich in carbohydrates. Some nuts yield oils hardly fit for human consumption, yet very valuable in soapmaking, while still others furnish oils used in making paints, varnishes and many other products. Some nuts are used only in making buttons, cigarette holders and other similar products of turnery.

While most nuts of leading importance are discussed separately elsewhere in alphabetical order, there is here included a list of many plant products commonly known under this name, together with an indication of their original source and the principal uses of either the nut or the plant, or both. Following are brief comments concerning a few that are of special interest.

The sweet almond is one of the world's best-known and best-liked nuts of the market. While of greatest importance as a crop in the Mediterranean basin, it is also of great importance in California and Australia. The bitter almond is grown chiefly in northern Africa. It is an important source of almond flavouring extract and prussic (hydrocyanic) acid.

Beechnuts are of little importance for human food, although in parts of Europe they are used as the source of a pleasing salad oil. The trees are of chief value for timber and ornamental planting.

The betelnut is chewed in the Philippines and other eastern tropics in much the same manner as tobacco.

Brazilnuts and sapucaianuts are close relatives from the Amazon region and elsewhere in northern South America. The former are well-known and much prized. The latter are not well known but are among the choicest nuts obtainable from any source.

The breadnut, a relative of the true breadfruit (*Artocarpus altilis*) is about an inch in diameter and contains a single seed, which when roasted or boiled is pleasant and nutritious.

The true butternut is the seed of a member of the walnut family which grows in northeastern United States and Canada. It is considerably hardier than is the Eastern black walnut but of less value for timber. Its kernels are preferred by some to those of any other *Juglans*.

The cashewnut is a native of the American tropics but is grown to greatest extent in southern India, Ceylon and East Africa. Marketed little except in the shelled and roasted condition, it is one of the cheapest and most pleasing of the world's nuts.

The castanopsis is a warm-country evergreen which produces a nut resembling the chestnut in bur and an oak in seed. It is eaten to a considerable extent although in flavour it is intermediate between an acorn and a chestnut.

The chestnuts were originally important as food and timber producers in Europe, Asia and North America. Between 1900 and 1940, the American and European trees, which were abundant in the eastern part of the United States, were practically destroyed there by chestnut blight. By 1943, much headway had been made toward reestablishing orchards with resistant strains and varieties of Chinese origin.

Common names in order of preference	Latin name	Original source	Principal use of nut or plant
Allegany oilnut; Elknut; Buffalonut	*Pyrularia pubera*	Eastern U. S.	Botanical interest
Almond (sweet)	*Prunus amygdalus*	Mediterranean basin	Food
Almond (bitter)	*P. amygdalus*, var. *amara*	Mediterranean basin	Flavouring extract; Prussic acid
Araucarian pinenut; Piñon; Pinyonie	*Araucaria araucana*	Chile	Food; Ornamental tree
Arnut; Yer-nut; Earth chestnut; Hawknut; Lousy-nut	*Bunium* spp.	Western Europe to Caucasus	Food
Babassu nut	*Orbignya oleifera*	Brazil	Food; Fuel oil; etc.
Bambarra-nut; Groundnut	*Voandzeia subterranea*	Tropical Africa	Food
Barbadosnut; Physic nut	*Jatropha curcas*	Tropical America	Medicine
Beechnut, American	*Fagus grandifolia*	Eastern U. S.	Mast; Timber
Beechnut, European	*Fagus sylvatica*	Central Europe; S.W. Asia	Salad-oil; Mast and timber
Ben-nut	*Moringa oleifera*	India and West Indies	Artists' oil
Betelnut; Arecanut; Pinang	*Areca catechu*	Eastern Pacific islands	Masticatory
Bladdernut, American	*Staphylea trifolia*	Temperate North America	Ornamental plant
Bladdernut, European	*Staphylea pinnata*	Southern Europe; S. Asia	Necklaces
Bomah-nut; Bome N.; Boomah N.	*Pycnocoma macrophylla*	Africa	Tanning; Poison plant
Bonduc nut	*Caesalpinia bonduc*	Tropics	Medicine; Beads
Brazilnut; Castanea; Creamnut; Paranut; Butternut; Niggertoe; Castana	*Bertholletia excelsa*	Northern South America	Food; Timber. *See* BRAZILNUT
Breadnut	*Brosimum alicastrum*	Tropical America	Food
Butternut; Long or White walnut	*Juglans cinerea*	Eastern U.S.; S.E. Canada	Food; Timber. *See* BUTTERNUT
Candlenut; Lumbang; Kukui; Varnish tree	*Aleurites moluccana*	Tropical Pacific islands	Manufacturing oil. *See* ALEURITES
Capechestnut	*Calodendrum capense*	Southern Africa	Ornamental plant
Cashewnut; Acajou; Caja; Cajou	*Anacardium occidentale*	West Indies and Tropical America	Food. *See* CASHEW
Castanopsis nut	*Castanopsis* spp.	S.E. Asia; California	Food; Ornamental evergreens
Chestnut, American	*Castanea dentata*	Eastern U. S.	Food; Timber; Tannin. *See* CHESTNUT
Chestnut, Chinese	*Castanea mollissima*	Northern China; Chosen	Food; Timber
Chestnut, European; Spanish, French, Italian C.; Marron	*Castanea sativa*	Southern Europe; N.Africa; S.W. Asia	Food; Timber
Chestnut, Japanese	*Castanea crenata*	Japan; Chosen	Food; Timber
Chilehazel	*Gevuina avellana*	Chile	Food; Ornamental plant
Chinkapin, Alabama	*Castanea alabamensis*	Southeastern U. S.	Food; Timber. *See* CHESTNUT
Chinkapin, Allegany; Dwarf chestnut	*Castanea pumila*	Southeastern U. S.	Food
Chinkapin, Ashe	*Castanea ashei*	Southeastern U. S.	Food; Tannin
Chinkapin, Florida	*Castanea floridana*	Southeastern U. S.	Food; Tannin
Chinkapin, Henry	*Castanea henryi*	China	Food; Timber
Chinkapin, Ozark	*Castanea ozarkensis*	Arkansas	Food; Timber
Chinkapin, Trailing; Creeping Chinkapin	*Castanea alnifolia*	Southeastern U. S.	Botanical interest
Chocolate nut; Cacao (Cocoa)	*Theobroma cacao*	Central and South America	Food and beverage
Chufa; Rush nut; Earthnut; Ground almond	*Cyperus esculentus*	Southern Europe	Food
Cobnut. See *Hazelnut* and *Filbert*, below			
Cobnut of Jamaica	*Ophalea triandra*	West Indies and Tropical America	Food
Coconut; Cocoanut	*Cocos nucifera*	Tropics generally	Food
Cohunenut; Cahoun nut	*Attalea cohune*	Honduras	Soap oil
Colanut; Kolanut; Ombene; Temperance nut; Bissy-bissy nut; Guru nut	*Cola acuminata*	West Africa	Food; Beverage
Coquilla nut	*Attalea funifera*	Brazil	Turnery
Coquita-nut; Monkey's coconut; Dwarf coco-nut; Coker-nut	*Jubaea spectabilis*	Chile	Soap oil
Cumaranut (Tonka or Tonquin bean)	*Dipteryx odorata*	Tropical South America	Perfume
Dika-nut	*Irvingia gabonensis*	West Africa	Food; Oil
Filbert, American (Hazelnut)	*Corylus americana*	Eastern North America	Food. *See* FILBERT
Filbert, Beaked	*Corylus cornuta*	Eastern North America	Food
Filbert, California	*Corylus californica*	West Coast of U. S.	Food
Filbert, Chinese	*Corylus chinensis*	Central and West China	Food; Timber
Filbert, European; Cobnut; Hazelnut	*Corylus avellana*	Europe	Food
Filbert, Giant	*Corylus maxima*	Europe	Food
Filbert, Himalaya	*Corylus ferox*	Himalayas	Food
Filbert, Japanese	*Corylus sieboldiana*	Japan	Food
Filbert, Mildred	*C. americana* x *avellana*	United States	Food
Filbert, Siberian	*C. heterophylla*	China; Siberia; Japan	Food
Filbert, Turkish; Constantinople hazel	*Corylus colurna*	Turkey; Southern U.S.S.R.; Himalayas	Food; Timber; Ornamental tree
Ginkgonut	*Ginkgo biloba*	China; Japan	Food; Timber; Ornamental tree
Goatnut. See *Jojoba*, below.			
Grugru nut; Corozo nut	*Acrocomia aculeata*	Tropical South America	Beads
Hazelnut. Synonym for Filbert			*See* FILBERT
Heartnut; Japanese walnut; Cordate W.	*Juglans sieboldiana cordiformis*	Japan	Food. *See* WALNUT
Hican (Pecan x shellbark hybrid)	*Carya illinoensis* x *laciniosa*	Indiana; Illinois; Iowa	Novelty trees and nuts. *See* HICKORY
Hickorynut, Bitter	*Carya cordiformis*	Eastern U.S.; Ontario	Timber; Nut inedible
Hickorynut, Black; Buckley hickory	*Carya texana*	Texas; Okla.; Arkansas	Food; Fuel
Hickorynut, Carolina; Southern Shag	*Carya carolinae-septentrionalis*	Southeastern U.S.	Food; Timber
Hickorynut, Cathay	*Carya cathayensis*	China	Food; Timber
Hickorynut, Fernow	*Carya fernowiana*	Southwestern U.S.	Food; Timber
Hickorynut, Hammock	*Carya ashei*	Southeastern U.S.	Timber; Fuel
Hickorynut, Mockernut; Bigbud H.; Bullnut	*Carya tomentosa*	Eastern U.S.; Ontario	Food; Timber
Hickorynut, Nutmeg	*Carya myristicaeformis*	Southwestern U.S.	Food; Timber
Hickorynut, Pig or Hognut	*Carya glabra*	Eastern U.S.; Ontario	Mast; Timber

Common names in order of preference	Latin name	Original source	Principal use of nut or plant
Hickorynut, Red; False shagbark	*Carya ovalis*	Eastern U.S.; Ontario	Food; Timber
Hickorynut, Sand; Paleleaf hickory	*Carya pallida*	Southeastern U.S.	Mast; Timber
Hickorynut, Scrub; Florida hickory	*Carya floridana*	Florida	Fuel
Hickorynut, Shagbark; Little scalybark; Tuscatine	*Carya ovata*	Eastern U.S.; S.E. Canada	Food; Timber
Hickorynut, Shellbark; Bigleaf H.; Bottom H.; Big scalybark	*Carya laciniosa*	Central, Eastern U.S.	Food; Timber
Hickorynut, Swamp	*Carya leiodermis*	Louisiana; Mississippi	Food; Fuel
Hickorynut, Tonkin	*Carya tonkinensis*	Southern China; Indo-China	Food; Timber
Hickorynut, Water; Bitter Pecan	*Carya aquatica*	Southern U.S.	Fuel; Inedible
Horsechestnut	*Aesculus hippocastanum*	Europe	Starch; Ornamental tree
Hyphaene-nut; Doum-nut; Dom-nut	*Hyphaene crinita*	South Africa	Turnery
Indiannut. Synonym for various North American edible pinenuts			
Javaalmond; Luzon-nut; Philippine N.	*Canarium commune*	Pacific Tropics	Food
Jojoba nut; Goatnut	*Simmondsia chinensis (californica)*	California and Mexico	Food and hair oil
Lychee; Chinese nut	*Litchi chinensis*	South China.	Food
Macadamia. Synonym for Queenslandnut			
Markingnut; Marany; Marsh nut	*Semecarpus anacardium*	India	Ink; Varnish
Marron. French name for large chestnuts			
Moretonbaychestnut; Black Bean	*Castanospermum australe*	Australia	Food
Mu-yu-oil-nut; Mu-yu-shu	*Aleurites montana*	South China.	Manufacturing oil. *See* ALEURITES
Nittanut; Nuttanut	*Parkia africana*	Africana	Food
Nutmeg	*Myristica fragrans*	East Indies	Spice
Nut Pine. Synonym for North American edible pinenut			
Olive-nut	*Elaeocarpus ganitrus*	India	Beads and turnery
Oysternut; Tabui	*Telfairia occidentalis*	Africa	Food
Palm nut	*Elaeis guineensis*	W. Africa	Oil. *See* PALM
Pascualito nut; Pinonchillo	*Garcia nutans*	Mexico to Venezuela	Hard, quick-drying oil
Peanut; Goober; Pindar; Groundnut	*Arachis hypogaea*	Brazil	Food. *See* PEANUT
Pecan; Illinois-nut	*Carya illinoensis*	Southern U.S.	Food; Ornamental tree. *See* HICKORY
Pekeanut. Synonym for Sawarrinut			
Pilinut	*Canarium ovatum*	Pacific tropics	Food
Pinenut; Indiannut	*Pinus* spp.		
Pinenut, Aleppo	*Pinus halepensis*	Southern Europe; W. Asia	Food
Pinenut, Colorado Pinyon	*Pinus cembroides edulis*	Southern Wyoming; Colo.; N. Mex.; Ariz..	Food
Pinenut, Coulter	*Pinus coulteri*	California	Food
Pinenut, Digger	*Pinus sabiniana*	California	Food
Pinenut, Italian Stone (Pignolia)	*Pinus pinea*	Mediterranean region	Food
Pinenut, Jeffrey	*Pinus jeffreyi*	California; Oregon	Food
Pinenut, Korean	*Pinus koraiensis*	Chosen; Japan	Food
Pinenut, Lacebark	*Pinus bungeana*	Northwestern China	Food
Pinenut, Limber	*Pinus flexilis*	Alberta to Texas	Food
Pinenut, Mexican Pinyon	*Pinus cembroides*	Southwestern U.S., Mexico	Food
Pinenut, Parry Pinyon	*Pinus cembroides parryana*	California	Food
Pinenut, Ponderosa	*Pinus ponderosa*	Western U.S.	Food
Pinenut, Singleleaf Pinyon	*Pinus cembroides monophylla*	Southwestern U.S.	Food
Pinenut, Sugar	*Pinus lambertiana*	Oregon to Lower California	Food
Pinenut, Swiss Stone (Pignolia)	*Pinus cembra*	Central Europe to Siberia	Food
Pinenut, Torrey; Soledad Pinenut	*Pinus torreyana*	Southern California	Food
Pinenut, Western White	*Pinus monticola*	Northwestern U.S.; B.C.	Food
Pinenut, Whitebark	*Pinus albicaulis*	Northwestern U.S.; B.C.	Food
Piñon. Synonym for Pinenut			
Pistachionut; Pistache; Green almond	*Pistacia vera*	Mediterranean basin to Southwestern Asia	Food. *See* PISTACHIONUT
Poisonnut	*Strychnos nuxvomica*	India	Medicine
Quandongnut	*Fusanus acuminatus*	Australia	Food
Queenslandnut; Australian nut; Macadamia; Australian hazel	*Macadamia ternifolia*	Australia	Food
Ravensara nut	*Ravensara aromatica*	Madagascar	Spice
Sapucaianut; Paradise nut	*Lecythis zabucajo*	Tropical South America	Food
Sassafras nut	*Ocotea* spp.	South America	Aromatic
Sawarrinut; Pekeanut; Peruvian almond; Butternut; Piki	*Caryocar nuciferum*	Peru; Brazil	Food
Sheanut	*Butyrospermum parki*	British Africa	Food; Soap oil
Snakenut	*Ophiocaryon paradoxum*	Guiana	Charm for snakebite
Soapnut	*Sapindus saponaria*	Southern Florida to Northern S. America	Washing; Ornament
Taguanut; Ivorynut; Vegetable ivory	*Phytelephas macrocarpa*	Central America	Buttons, etc.
Tahiti-chestnut; South Sea chestnut	*Inocarpus fagiferus*	South Seas	Food
Tallownut, Chinese	*Sapium sebiferum*	China	Wax for soap and candles
Tropical-almond; Myrobalan; Tavolanut; Demerara almond	*Terminalia catappa*	Southwestern Asia	Food; Street tree
Tungnut; Wood-oil tree	*Aleurites fordii*	South China.	Paint and varnish. *See* ALEURITES

Walnut, American	*Juglans nigra*	Eastern U.S.	Trade name for lumber of this sp.
Walnut, Ancona	*Juglans regia*	Persia	Trade name indicating streaked figure in Persian Walnut
Walnut, Argentine	*Juglans australis*	Argentina	*See* WALNUT
Walnut, Arizona Black	*Juglans major*	Southwestern U.S.	Food; Lumber

Common names in order of preference	Latin name	Original source	Principal use of nut or plant
Walnut, Bixby	*J. cinerea* x *sieboldiana*	U.S.	Food; Novelty tree
Walnut, Bolivian Black	*Juglans boliviana*	South America	Food; Lumber
Walnut, California (S. Calif.) Black	*Juglans californica*	Southern California	Food; Lumber
Walnut, Cathay	*Juglans cathayensis*	China	Food; Fuel
Walnut, Circassian	*Juglans regia*	Persia	Trade name for lumber of Persian W.
Walnut, Claro		California	Trade name for lumber of California and Hinds Walnuts; also California hybrid walnuts
Walnut, Colombian	*Juglans columbiensis*		
Walnut, Cuban	*Juglans insularis*	Cuba	Lumber; Food
Walnut, Eastern Black	*Juglans nigra*	Eastern U.S.; Ontario	Lumber; Food
Walnut, Ecuador	*Juglans honorei*	Ecuador	Lumber; Food
Walnut, Guatemalan	*Juglans mollis*	Guatemala	Lumber; Food
Walnut, Hinds; N. California Black W.	*Juglans hindsii*	Northern California	Food; Shade; Lumber
Walnut, Intermediate	*J. nigra* x *regia*	U.S.	Hardy ornamental
Walnut, Manchu; Manchurian W.	*Juglans mandshurica*	N. China; Manchuria; Chosen	Food; Fuel
Walnut, Nigornica	*J. californica* x *nigra*	California	Vigorous ornamental
Walnut, Nigrind	*J. hindsii* x *nigra* (Paradox in part)	California	Vigorous ornamental
Walnut, Nigroldiana	*J. nigra* x *sieboldiana*	U.S.	Ornamental tree
Walnut, Notha	*J. regia* x *sieboldiana*	U.S.	Ornamental tree
Walnut, Perbut	*J. cinerea* x *regia*	U.S.	Ornamental tree
Walnut, Persian; English; French; Turkish; Italian; Roumania; Common *et al.*	*Juglans regia*	Persia	Food; Lumber; Ornamental tree
Walnut, Regifornica	*J. californica* x *regia* (Paradox in part)	California	Vigorous ornamental tree
Walnut, Siebold; Japanese walnut	*Juglans sieboldiana*	Japan	Food; Ornamental tree; Fuel
Walnut, Texas	*Juglans rupestris*	Texas, Oklahoma; N. Mex.	Food; Ornamental tree; Fuel
Waterchestnut	*Trapa natans*	South China	Food; Conservatory plant
Waternut	*Eleocharis tuberosa*	South China	Food
Wingnut; Caucasian walnut; False walnut	*Pterocarya fraxinifolia*	Southwestern Asia	Ornamental tree

The chinkapins are closely related to the chestnuts, but are generally inferior in size of nuts and in timber values.

The chocolate nut is the source of the well-known material used in making candies and cocoa. It is extensively cultivated in many tropical regions.

The chufa is a small sedge plant producing a nut-like tuber underground which is an important hog food in the tropics and subtropics. While edible, it is rarely used as human food.

The coconut is the fruit of a palm grown in practically all tropical regions, where it furnishes food, healthful drinks, intoxicants, fibre and coconut oil.

Colanuts, now much cultivated in the American tropics, are the source of an important article of commerce used in making mildly stimulating drinks.

Coquilla nuts, or "coquilhos" as known in Portuguese, are the small coconut-like seeds of the piassava palm of Brazil. They are a by-product from the tree; the main product is fibre. They are elongated oval and 3 or 4 in. long and much used in turnery.

Coquita-nuts are the small, roundish seeds of the Syrup palm from Chile which is much prized as a conservatory plant. The seeds furnish an oil used in making soap.

The filberts are seeds of a number of temperate zone species, some of which are low shrubs while others become large trees. The nuts are roundish or oblong, yellowish brown, usually with gray tomentum over the apical end, a medium thin shell and a single kernel, which is usually slightly hollow at the centre. The filbert is one of the half-dozen or so most important nut-bearing plants of the north temperate zone.

The ginkgonut is the small, whitish, smooth-shelled seed of the Oriental ginkgo tree, also known as Maidenhair tree and as Kew tree. It forms within a fruit greatly like the American persimmon in its mushiness, but exceeding it in foul odour. The seed is roasted by Chinese, who are said to regard it as a great delicacy.

The several hickorynuts, including the pecan, are important food crops grown in the eastern and southern United States. Of these the pecan is the choicest and far the most important. Several others are of great value for their timber.

The javaalmond and the pilinut are close relatives from the eastern Pacific islands, including in particular the Philippines. The shells are very hard and thick, yet the kernels are regarded by many as being fully equal to any other nuts on the world's market.

The lychee is a brownish, roundish, thin, papery and pimpled-shell product containing a raisin-like pulp surrounding a hard, smooth-shelled seed. The edible portion is the pulp. This nut is common in most Chinese stores. It is considered a great delicacy.

The markingnut is closely related to the cashew and is equally poisonous in its effects upon the skin of susceptible persons. The immature juice of the nut is mixed with quicklime and used as an ink. When dry, the juice is the basis of a valuable caulking material and varnish. The seed is edible and is the source of a useful oil.

The pinenuts are seeds of a considerable number of species, native to remote and often more or less arid parts of the earth. The nuts are borne in the axils of the cone scales. The stone pines of Europe and Asia, the pinyon pines of North America, and the Araucarian pine of the Andean region of South America are the most important. With the exception of the Italian stone pine, the seeds of which are sold as "pignolia" and exported, pinenuts are largely consumed in the general regions where they are produced. They are fairly rich in oil and are very pleasing to the taste.

The pistachionut is the small, whitish, thin, but bony-shelled seed of a medium or small-sized tree native to the region including the Mediterranean basin and extending to southwestern Asia. The kernel is of fine texture and of pale green colour throughout; it is much used in colouring and flavouring confections. It is fairly rich in fat.

The quandong is a small, roundish, thick-shelled seed of an Australian tree which is mainly used as a preserve.

The ravensara nut is a Madagascar product considerably used as a spice under the trade name of "clove nutmeg," although it is not a true nutmeg.

The sawarrinut is the fruit of a tall-growing tree, the forest timber of which is used in building ships. The trees are cultivated in the American tropics for their very fine nuts. The latter are seldom seen in the world's market, except locally.

The taguanut is the inedible seed of a palm from northern South America, which becomes exceedingly hard and is much used in making buttons. It takes a high polish, colours well and burns with intense heat.

The tungnuts and their close relatives, the candlenut and the mu-yu-oil-nut, are sources of valuable oils used in many forms of manufacture. (*See* ALEURITES.)

2. Pecan, *Carya illinoensis*. Staminate flowers on branch
3. American chestnut, *Castanea dentata*. Flowers and leaves
4. Eastern black walnut, *Juglans nigra*. Staminate and pistillate flowers

The waterchestnut and its close relative, the singharanut, are important sources of human food, rich in starch. Both are annuals extensively grown in the Asiatic subtropics. The former is very abundant in the slow-moving or stagnant waters in the vicinity of the Yangtze river. It multiplies rapidly and may easily get beyond control, as it has in alcoves of the Potomac river below Washington, where it forms a practically impassable blockade at many points near the shore.

The waternut (*matai* in Chinese) is the edible corm of a sedge plant grown under irrigation in southern China. It is much used in making chop suey and is well suited to occidental cookery. The wingnut is the winged seed of a highly ornamental tree from western China. The nut is too small to be of value. (C. A. Rd.)

Nut Culture in the U.S.—Numerous varieties of the pecan are planted for commercial production in the southern states. Hardy strains are producing successfully, however, in Missouri and Illinois. In 1937, which was an excellent year, the U.S. production was estimated by the U.S. department of agriculture at 76,893,000 pounds. The yearly average for 1927–36 was 61,274,000 pounds. Texas led all other states in this ten-year period with an average annual yield of 23,380,000 pounds.

The commercial production of almonds is restricted to various forms of the sweet variety (var. *dulcis*), with increasing preference for those having thinner walls in the stone, as in the paper-shell almonds. The climatically suitable districts are comparatively limited, being confined chiefly to the Pacific states. In California, which usually grows about 99% of the United States crop, the production of almonds in 1938 was approximately 12,100 tons; in 1937, an unusually good year, it was about 20,000 tons.

The commercial production of the old world or Persian walnut, in the United States often called English walnut, has attained its greatest development in specially selected and prepared soils under irrigation in California. However, hardy strains are grown locally with considerable success in the eastern states from Massachusetts westward and southward to Arkansas, especially in climatic situations similar to the Great Lakes region of western New York; Oregon also produces a considerable quantity. In California, where more than 90% of the commercial crop is ordinarily grown, the estimated production in 1938 was 44,000 tons.

NUT (Engineering): *see* Bolt.

NUTATION [from Lat. *nutare,* to nod], a deviation of the celestial pole from its mean position, due to inequalities in the action of the sun and moon on the equatorial protuberance of the earth. The main part of the nutation is a motion of the pole in a circle of 9″ radius in a period of 18.6 years. *See* Precession of the Equinoxes.

The name is also used in reference to the phenomena of certain organs in plants which bend alternately in opposite directions. In some cases the apex of the stem will describe a spiral movement, inclining to all points of the compass in succession; this being termed *circumnutation. See* Lianes.

NUTCRACKER (*Nucifraga caryocatactes*), a European bird of the crow family (*Corvidae*). The plumage is mottled and the tail feathers have conspicuous white tips. The beak is long and the flight undulating. The nutcracker feeds mainly on conifer seeds, but also takes fruits, insects and young birds. The nest is built on the bough of a tree, about 20 ft. from the ground, and is a large structure of sticks lined with grass. The eggs are of a very pale bluish-green, freckled with pale olive or ash colour. Another species (*N. columbiana*) is found in America.

The Siberian nutcracker migrates into western Europe in large flocks, at intervals of approximately 11 years. *See* also Crow.

NUTHATCH, a small bird, so called from its habit of hacking or chipping nuts, which it cleverly fixes, as though in a vise, in a chink or crevice of the bark of a tree, and then hammers with the point of its bill till the shell is broken. The common nuthatch, *Sitta europaea,* is widely distributed through Europe and Asia, some two dozen local races being recognized. The type form, *S.e.europaea,* described by Linnaeus, lives in Scandinavia and north Russia; *S.e.affinis* in England; *S.e.caesia* in middle Europe; and other races in Spain, the Atlas mountains, Italy, Sicily, Asia Minor, Iran, China, Japan, the Caucasus mountains, Siberia, and Kamchatka.

Without being very plentiful anywhere, it is generally distributed in suitable localities throughout its range, those localities being such as afford it a sufficient supply of food. During the greater part of the year it feeds on insects, which it diligently seeks on the boles and larger limbs of old trees, but in autumn and winter it feeds on nuts, beech-mast, the stones of yew-berries and hard seeds. Its bold disposition and the fact that trees favouring its mode of life often grow near houses make it quite tame and it will become familiar with humans on slight encouragement. Its feathers are ash-gray and warm buff and its manner is sprightly. It generally makes its nest in a hollow branch, plastering up the opening with clay and leaving only a circular hole, just large enough to afford entrance and exit. The interior contains a bed of dry leaves or the filmy flakes of the inner bark of a fir or cedar, on which the eggs are laid.

The rock nuthatches, *S. neumayeri* and its races and close relatives, nest and hunt among rocks rather than trees; they range from southeast Europe to Palestine, Iran, and Turkestan. Four other little-known species of *Sitta* occur in various parts of Asia. Four familiar species, using no mud in the nest, are found in North America: red-breasted nuthatch, *S. canadensis,* mostly in Canada but southward in mountains to North Carolina and to California and New Mexico; white-breasted nuthatch, *S. carolinensis,* southeast Canada to South Carolina and northern Texas, with six races, two in Lower California, one in the Panamint and White mountains of California, southeastern United States, Rockies from Canada into Mexico, and the Pacific coast and its ranges; brown-headed nuthatch, *S. pusilla,* of the southeastern United States, with a local race in Florida; and pygmy nuthatch, *S. pygmaea,* of the middle California coast, with one local race from southern California into Lower California and another along the Rockies from British Columbia to the Mexican border.

No nuthatches are found in South America, none in Africa from the Sahara southward, none in New Zealand. A peculiar genus with a single species, *Hypositta corallirostris,* is confined to Madagascar. The Malay velvet-fronted nuthatch, pink and black, and the deep-blue nuthatch with a beautiful blue belly, belong to an allied genus, *Dendrophila,* living in India and the Malay countries and islands. The genus *Neositta,* comprising some seven species and various races of Australian tree-runners, is also found in New Guinea, to which the single species of *Daphoenositta* is confined.

NUTKA. This people held the west coast of Vancouver island, and with the Makah of Cape Flattery form one branch of the Wakashan family, the Kwakiutl constituting the other. The speech relationship of Nutka and Kwakiutl is not close, and the two bodies must have been distinct a long time. Nutka culture is that of the north Pacific coast, with specializations, such as whale hunting, that reflect frontage on the open ocean. Their trade influence is shown by the considerable proportion of words they contributed to the composite Chinook jargon. (*See* G. M. Sproat, *Scenes of Savage Life,* 1868.)

NUTLEY, a town of Essex county, New Jersey, U.S.A., on the Passaic river, 13 mi. W. of New York city, adjoining Belleville and Bloomfield. It is served by the Erie railroad and bus lines. Industries include pharmaceutical chemicals, woollen goods, paper and electric insulation, but the town is primarily a suburban residential community. The population was 26,992 in 1950 and 21,954 in 1940 by the federal census. Nutley was originally called Franklin, after William Franklin, governor of the colony of New Jersey from 1763–76.

NUTMEG, the commercial name of a spice representing the kernel of the seed of *Myristica fragrans,* a dioecious evergreen tree, about 50 to 60 ft. high, found wild in the Molucca islands and extending to New Guinea. Nutmeg and mace are mostly obtained from the Molucca islands, although the cultivation has been attempted with varying success in Singapore, Penang, Bengal, Réunion, Brazil, French Guiana and the West Indies. The trees yield fruit in eight years after sowing the seed, reach their prime in 25 years, and bear for 60 years or longer. Almost the whole surface of the Molucca islands is planted with nutmeg trees,

which thrive under the shade of the lofty *Canarium commune.* The ripe fruit is about 2 in. in diameter, of a rounded pear-shape, and when mature splits into two, exposing a crimson aril surrounding a single seed. When the fruit is collected the pericarp is first removed; then the aril is carefully stripped off and dried, in which state it forms the mace of commerce. The seed consists

NUTMEG (MYRISTICA FRAGRANS), SHOWING (A) SEED WITH ARIL (MACE) ROUND IT; (B) BRANCH SHOWING RIPE FRUITS, ONE OF WHICH IS SPLITTING AND SHOWS SEED INSIDE; (C) TWIG WITH FLOWERS

of a thin, hard shell, enclosing a wrinkled kernel, which, when dried, is the nutmeg.

To prepare the nutmegs for use, the seed enclosing the kernel is dried at a gentle heat in a drying-house over a smouldering fire, the seeds being turned every second or third day. When thoroughly dried the shells are broken and the nutmegs picked out and sorted, the smaller and inferior ones being reserved for the expression of the fixed oil which they contain, and which forms the so-called oil of mace.

"Oil of mace," or nutmeg butter, is a solid fatty substance of a reddish-brown colour, obtained by grinding the refuse nutmegs to a fine powder, steaming it and then compressing it while still warm. The brownish fluid which flows out being afterwards allowed to solidify. Nutmegs yield about one-fourth of their weight of this substance. It is partly dissolved by cold alcohol, the remainder being soluble in ether. The latter portion, about 10% of the weight of the nutmegs, consists chiefly of *myristin,* which is a compound of *myristic acid,* $C_{14}H_{28}O_2$, with glycerin.

The name nutmeg is also applied to other fruits or seeds in different countries. The Jamaica or calabash nutmeg is derived from *Monodora Myristica,* the Brazilian from *Cryptocarya moschata,* the Peruvian from *Laurelia sempervirens,* the Madagascar or clove nutmeg from *Agathophyllum aromaticum,* and the Californian or stinking nutmeg from *Torreya californica.*

NUTRITION. Despite the fact that life may be continued for many weeks without food and for several days without water, for the practical maintenance of life we must have a regular intake of food; nutrition must go on. Food is required for two main purposes: (1) to supply the necessary energy for the production of internal and external work and the maintenance of the body temperature and (2) to supply the necessary material to make good the wear and tear of the tissues in the adult and also, especially in the child, the material required for growth. The study of the problem of nutrition demands therefore the study of the methods by which the various foodstuffs are digested, absorbed and utilized in the body and further how the waste products formed during the various tissue activities are got rid of.

The evidence available would seem to point to the fact that the majority of mankind eat too much rather than too little. Excessive intake may prove to be, probably is, harmful. Certain experiments carried out for purely commercial purposes on the breeding of pelt-bearing animals go to show that such animals do best on a diet just slightly in excess of the bare maintenance ration. (*See* DIET AND DIETETICS.)

CHEMISTRY OF DIGESTION

The essential step which prepares the ordinary food for utilization in the body, for the change into living matter, is digestion, a process which the food undergoes under the influence of the ferments or enzymes present in the gastro-intestinal tract. By this process it is broken down into simpler substances, which can be utilized by the body tissues for conversion into protoplasm and as the supply of energy.

Enzyme Action in General.—The substances which bring about this change are known as ferments, enzymes or zymins. Formerly it was believed that there were two distinct classes of enzymes: those which were living or associated with living cells, and those which were non-living. In 1897, however, E. Buchner and M. Hahn showed that from living cells (yeast) a ferment could be obtained which acted quite as well extracellularly as when it was bound up within the cell. Subsequent work has shown that other organisms act by the enzymes they contain, so that it is now recognized that there is no essential difference between the living or organized ferment and the non-living or unorganized ferment. All ferments probably act as catalysts. Catalysis (*q.v.*) is the process by which reactions are either initiated or accelerated by the mere presence of certain substances which remain unchanged during the process. It has been shown that the action of ferments is specific; *i.e.,* the ferment only exerts its action on definite substances or substrates of definite structural arrangement. The relation of ferment to substrate has been compared to that of a key to its lock. Ferments which bring about the breakdown of proteins are without influence on fats and carbohydrates; those which decompose fats leave proteins and carbohydrates untouched, and so on.

The chemical composition of enzymes is unknown, but it would seem certain that all enzymes have not the same chemical structure. One of their most important physical properties is their colloidal nature, shown by the fact that they cannot, or only with extreme difficulty, pass through a parchment membrane.

Most of the ferments are soluble in water or saline solutions, and in glycerol and water. The ferments are found to have an optimum temperature of action. This temperature in most cases ranges from 37° to 40° C. All true ferments are thermolabile, being destroyed at about 70° C. The action of many of them is retarded when the products of their action are allowed to accumulate. Just as when a chemical reaction is set up its rate tends to decrease and finally comes to a standstill before the reaction is completed—an equilibrium being established—so the reactions set up by enzymes also tend to come to an equilibrium before the complete conversion of the original substance.

A number of the body ferments have now been shown to exist in the tissues in an inactive form. This condition is known as the proferment or zymogen state, and before any action can be exerted it must be activated, usually by some specific substance, as in the case of the activation of trypsinogen by means of enterokinase. The table on page 649 gives a list of the principal ferments concerned in the digestion and metabolism of food-stuffs.

Certain oxydases, catalases and de-aminizing enzymes are found in the tissues generally and play an important part in the various metabolic processes.

Digestion in the Mouth.—The first of the digestive secretions which food encounters is the saliva. It is produced by the three large salivary glands, the parotid, the sub-maxillary and the sub-lingual, is a colourless or slightly turbid viscous fluid with a faintly alkaline reaction and of low specific gravity, and exercises a twofold function. First, it has a mechanical action moistening the mouth and the food and thus aiding mastication and swallowing by securing the formation of a proper bolus

Material acted on	Enzyme	Where found
I. Protein	Pepsin	Gastric juice
	Trypsin	Pancreatic juice
	Erepsin	Small intestine
	Various autolytic enzymes	Tissues generally
II. Fats	Lipase	Pancreatic juice and certain tissues
III. Carbohydrates	Ptyalin (salivary diastase)	Saliva
	Pancreatic diastase	Pancreatic juice
	Maltase	Pancreatic juice
		Small intestine
	Invertase	Small intestine
	Lactase	Small intestine
	Various tissue diastases	Liver, muscle, etc.

of food; it also assists by binding the particles together, an action of special importance when the food is dry. Second, in man and in some of the lower animals the enzyme ptyalin exerts an action in digestion on part of the carbohydrates of the diet. The starches or polysaccharides are broken down, first of all to the simple dextrins and then to the still more simple disaccharide, maltose. The action of ptyalin on starches is thus very similar to that of acids, except that it stops at the formation of maltose. Ptyalin acts best at a temperature of about 40°C and in a neutral or faintly alkaline medium, its action being inhibited by the presence of even very dilute solutions of the mineral acids. If the acid be in sufficient amount the enzyme is destroyed. For this reason the action ceases in the stomach whenever the bolus is completely permeated by the gastric juice. As it takes time for the gastric juice thoroughly to permeate the food mass, which remains for a considerable period in the fundus of the stomach unmixed with the secretion, salivary digestion goes on for about half an hour after food is taken.

Gastric Digestion.—The stomach has two digestive functions: (i.) it acts as a store chamber permitting a full meal to be taken; (ii.) it acts as a digestive organ of importance in preparing the food for further attack in the intestinal canal. But the stomach cannot be regarded as an essential organ, since it has been removed in dogs and in man without apparent interference with health.

Gastric digestion is brought about by the action of the gastric juice, a clear watery, colourless and strongly acid fluid with a specific gravity of about 1003. The amount of hydrochloric acid present in the juice varies with the period of digestion. The acid exists in the stomach in two forms, as free hydrochloric acid and as combined hydrochloric acid The amount of each depends on various factors: (i) the secretion itself; (ii.) the nature of the food; and (iii.) the rapidity with which the stomach empties itself, etc. For instance, after a protein-free meal the hydrochloric acid is for the most part free, whereas, when protein is present, it combines with it and, unless secreted in very large amount, most of the acid is in a fixed condition.

The hydrochloric acid is formed by the activities of certain gland cells in the middle region of the stomach, and the fact that it does not exist as such in the blood proves that it is formed within these cells. That the chlorine comes from the sodium chloride in the food has been shown by the fact that, when the tissues are deprived of this salt, and sodium bromide is given, hydrobromic acid may appear in the gastric secretion.

The hydrochloric acid is essential for the action of the gastric enzyme, pepsin, in splitting up the protein of the food. In addition to this, the acid has a slight action in splitting polysaccharides and disaccharides. Lastly, it acts as a bactericidal agent, preventing bacterial decomposition from taking place, and it may thus prevent certain noxious bacteria, taken in in the food, from gaining access to the intestinal tract, where there is a chance of their flourishing in the rich alkaline medium.

The quantity of juice secreted varies with the nature of the food consumed. Each separate food seems to give rise to a definite hourly secretion of the juice and to a characteristic alteration in its properties.

The principal ferment found in the gastric juice is pepsin, which acts only in the presence of a mineral acid. The action proceeds best at a temperature of about 37°C in an acid medium of 0·2% to 0·3%. Pepsin is elaborated in the so-called chief cells of the gastric glands as an inert precursor—propepsin. It is only when it comes into contact with the acid of the juice that it is activated into attacking the protein of the food.

As already mentioned, the main function of the gastric juice is to deal with the protein moiety of the food and to prepare it for further digestion in the intestine. The first result of the action of this secretion on protein matter is to render it soluble—a metaprotein or acid albumin being formed. This body may be regarded mainly as the product of the action of the hydrochloric acid independently of the pepsin.

The following steps of decomposition are the result of the action of pepsin. From the metaprotein primary and secondary proteoses are formed, and from these peptones are finally produced. The result of this process of digestion or hydrolysis induced by the pepsin is that complex insoluble protein substances of high molecular weight are converted into simpler soluble protein bodies of comparatively low molecular weight. The contents of the stomach—products of protein digestion—are passed on into the duodenum, chiefly as proteoses and peptones.

In addition to pepsin some workers hold that another enzyme is present in the gastric juice. This is the ferment rennet, rennin or chymosin, the sole action of which, so far as is known at present, is to bring about the curdling of milk, the curd formed being subsequently dealt with in the ordinary way by the pepsin. Clotting of milk under the action of rennin occurs at a suitable temperature with great rapidity. This process is said to take place in two stages: (1) the rennin converts the caseinogen of the milk into soluble casein, and (2) this soluble casein unites with the lime salts present in the milk and forms the curd or precipitate. That lime salts are absolutely essential for this process of clotting has been shown by the fact that, if they are removed by precipitation as by oxalates, no clotting will take place even after the addition of a large amount of active rennin. Immediate clotting takes place, however, when the necessary lime salts are restored.

The speed with which the stomach empties itself depends to a great extent on the nature of the food. Plain water leaves the stomach almost at once, salt and sugar solutions at a somewhat slower rate. On a mixed diet, emptying of the stomach in man proceeds very slowly, requiring about four hours. Cannon, by feeding with food impregnated with bismuth and using X-rays, showed that carbohydrates leave most rapidly, then mixtures of carbohydrates and proteins, then proteins, then fats and finally mixtures of fats and proteins. The diet which remains longest in the stomach is a mixture of fats and proteins—rich food, as it is popularly called. Here two factors enter to prevent rapid emptying: (1) the presence of much fat, and (2) the acid secretion engendered by the abundant protein.

There is no doubt that fats present in fine emulsion can be decomposed in the stomach. The action proceeds in a medium which is slightly acid or neutral, being entirely prevented by the presence of strong acids and alkalis. Many workers believe this gastrolipase to be of pancreatic or intestinal origin, and suppose that it gains entrance to the stomach by a reflux flow through the pylorus.

No specific enzyme for carbohydrates has been found in the stomach in man. Certainly a small amount of polysaccharide decomposition takes place, but this is dependent (1) on the ptyalin which comes from the mouth, and (2) on a certain amount of hydrolysis due to the action of the free hydrochloric acid.

Digestion in the Intestine.—The food so far digested in the stomach is known as chyme, and it is passed on to undergo intestinal digestion under the influence of (1) the enzymes of the pancreas, and (2) of other enzymes present in the different secretions of the intestine.

Pancreatic Digestion. The pancreatic juice is the secretion from the pancreas and is discharged into the duodenum. It is a clear, usually thin fluid with a specific gravity of about 1008, and with an alkaline reaction. The most important inorganic constit-

uent is sodium carbonate, which gives the alkaline reaction. This alkaline salt, along with that contained in the intestinal juice, plays an important part in neutralizing the acid chyme.

In the pancreatic secretion there are at least three important enzymes, each with a definite action: (*a*) trypsin, the proteolytic enzyme which brings about the further breakdown of the food proteins; (*b*) a diastase which deals with the carbohydrates, and (*c*) a lipase which acts on the fats.

(*a*) *Trypsin.* This ferment, in the form in which it is secreted—trypsinogen—is inert. Before it can exert its hydrolytic action it must be activated. This activation is brought about by another enzyme found in the intestinal tract—enterokinase. The conversion is brought about as soon as the trypsinogen comes into contact with the enterokinase, the merest trace of which suffices to activate a large amount of trypsinogen.

Trypsin acts on the protein just as pepsin does, by bringing about hydrolytic changes. It differs from the latter in acting best in an alkaline or neutral medium. Its effect is much more energetic than that of pepsin, so that the protein molecule is more completely decomposed.

The character and properties of the products formed in such digestion depend on the nature of the protein acted upon. As will be seen from the following table, proteins vary fairly widely in the proportion of amino acids which they contain.

Approximate Amino-Acid Percentage Composition of Several Proteins

	Gliadin (wheat)	Gelatin	Caseinogen (milk)	Albumin (milk)	Fish muscle (protein)	Ox muscle (protein)
Glycine	0·0	25·5	0·45	0·37	0·00	2·06
Alanine	2·0	8·7	1·85	2·41	+?	3·72
Valine	3·34	0·0	7·93	3·30	0·79	0·81
Leucine	6·62	7·1	9·7	14·03	10·33	11·65
Phenylalanine	2·35	1·4	3·88	1·25	3·04	3·15
Tyrosine	3·04	0·0	5·36	1·95	2·39	2·20
Serine	0·20	0·4	0·5	1·76	(?)	(?)
Cystine	2·40	0·16	0·25	4·1	.	..

Hydroxyproline	?	14·1	0·23	0·0	..	..
Aspartic acid	0·58	3·4	4·1	9·30	2·73	4·51
Glutamic acid	43·66	5·8	21·77	12·89	10·13	15·49
Hydroxyglutamic acid o	2·40	..	10·5	10·00	..	..
Tryptophane	1·10	0·0	1·6	2·40	Present	Present
Arginine	3·2	8·22	3·81	3·47	6·34	7·47
Lysine	0·63	5·92	8·38	9·87	7·45	7·59
Histidine	1·49	2·94	2·5	2·61	2·55	1·76
Ammonia	5·22	0·49	1·61	1·31	1·33	1·07

(*b*) *Diastase.* This ferment is found in the pancreatic juice apparently secreted in an active form, although some observers hold that it also is secreted in a zymogen form. It is practically identical in its action with the ptyalin of the saliva, converting starch into maltose. It deals with all the starchy food which has escaped conversion into the simple sugars by the ptyalin.

(*c*) *Lipase.* Most of this ferment, if not all, is apparently secreted in the form of a zymogen. There is evidence that the bile salts are the activating agent here, just as the enterokinase acts in the case of trypsin. Lipase can act in any medium acid, neutral or alkaline, and both on emulsified and non-emulsified fats. It converts the fats by a process of hydrolysis into fatty acids and glycerol. It has been found that not only can this enzyme break up fats into their components, but that it also has the power to act in the reverse direction, and in this way bring about the union of fatty acids and glycerol so as to form fats, a process which occurs in the intestinal epithelial cells after absorption.

2 *Intestinal Digestion.* By this is meant the other digestive processes which go on in the intestine under the action of the secretion of Lieberkühn's follicles—the *succus entericus.* This is a yellowish, often opalescent, strongly alkaline fluid. The alkalinity is due to the presence of sodium carbonate. Most of the ferments are found in very small amount in the intestinal juice. They seem to be present actually within the epithelial cells lining the intestine, for extracts made from the intestinal mucous membrane are richer in ferments than the secretion.

The intestinal secretion contains no trace of a ferment acting on native protein, but a ferment—erepsin—is present in fair amount in the intestinal mucous membrane and in small amount in the secretion, which acts in an alkaline medium on proteoses, peptones, and on casein, converting them into amino acids. A lipase has also been detected which is very similar to pancreatic lipase; it, however, attacks only emulsified fats.

Several carbohydrate hydrolysing enzymes have been described in the small intestine. Invertase, the ferment which splits cane-sugar, is present in small amount in the secretion, more abundantly in the extract of mucous membrane. In all probability it deals with the saccharose after or in process of absorption. Maltase is also present in large amount, and here again in greater amount in the extract than in the secretion. The question of the presence of lactase has been much discussed, and it seems probable that suckling animals do possess this enzyme.

Bile.—This fluid, in all probability, has little direct action in ordinary digestion, although it contains substances which act indirectly. The bile salts act as solvents for fats and fatty acids, and as activators of pancreatic lipase. The salts also serve to keep cholesterol in solution. Bile is to be looked upon rather as an excretion, the result of the hepatic metabolism, than as a digestive juice. It has an orange-brown colour, but the colour varies according to the pigment present. It is more or less viscous (not so viscous as bile taken from the gall bladder) and has a specific gravity of about 1010. It has a slightly alkaline reaction, a bitter taste and a characteristic smell. On analysis it is found to have over 2% of solids, of which more than half are organic. It contains in addition to a nucleo-albumin, derived mainly from the bile passages and gall bladder, bile acids, bile pigments, cholesterol, lecithine, etc. The most abundant solids are the salts of the bile acids, of which in man the most important is sodium glycocholate, sodium taurocholate being present in small amount. The bile acids are formed in the liver cells, and when the duct is ligatured they tend to accumulate in the blood.

The pigments amount to only about 0·2%. In human bile the chief pigment is bilirubin, whilst in herbivores biliverdin is more abundant. They are derived from the haemoglobin of the blood, but the pigments are iron-free. They may be regarded as purely excretory products arising from the breakdown of the haemoglobin of effete blood corpuscles.

Cholesterol is a monatomic alcohol, and is probably a waste product. Fats and lecithine are both derived from the liver cells. Of the inorganic constituents calcium phosphate is the most abundant.

The secretion of bile is practically continuous, but it seems to enter the duodenum intermittently. The taking of food increases the flow of bile. The entry of the acid chyme into the duodenum is the stimulus which brings about the ejection of the bile.

Faeces.—The bulk of the waste matter arising from the foods along with the secretions from the alimentary canal form the faeces. On a diet giving little residue the faeces are almost purely intestinal in origin. As a channel of excretion of nitrogenous metabolic waste products they are not very important, although they do play a certain part. The nature of the excreted nitrogenous substances has not been fully examined. It is, however, very difficult to come to any definite conclusion as to what is unabsorbed material and what excreted.

ABSORPTION

Stomach.—No absorption of food-stuffs takes place in the mouth. Absorption from the stomach occurs only to a small extent. Water passes rapidly through the stomach and is practically unabsorbed. Salts are apparently absorbed in a limited amount from their watery solution, the extent of absorption depending to some extent on the concentration of the solution. Sugar is also absorbed to a small extent from its solutions. Alcohol is readily absorbed from the stomach. A small amount of the products of protein digestion may be absorbed. There is no evidence that fats are absorbed under any conditions.

Intestine.—The greatest absorption of the foods takes place in the intestines, especially in the small intestine. It has been shown that practically all the protein digest products have disappeared before the lower end of the small intestine is reached. There are two channels for the removal of the material from the intestine: (1) the blood capillaries spread in the villi, and (2) the lacteals also present in the villi. The foods may reach the blood direct or through the various lymph channels into the thoracic duct and finally into the blood. The lacteals of the villi are channels for the absorption of the fatty parts of the food. The products of the digestion of the proteins and carbohydrates reach the body directly through the capillaries via the portal system. Whether the nervous system plays any part in absorption is not yet determined.

Carbohydrates. These reach the body, as already mentioned, by way of the blood, and in the form of monosaccharides or simple sugars. It has been shown that if lactose be put into a lactase-free intestine, no absorption takes place, the lactose gradually disappearing under bacterial action, whereas when the ferment lactase is present, glucose and galactose, the products of its splitting, are absorbed as readily as cane-sugar and maltose. The body deals with its carbohydrate supply in the form of monosaccharides as if solutions of various sugars, mono- and disaccharides be injected, it is found that the simple sugars are retained, whereas the double sugars are excreted in the urine. The only disaccharide which can be dealt with in the body is maltose, as there is a maltase present in the blood which splits it. Carbohydrates which are not absorbed from the intestine are disposed of by bacterial action.

Fats. Fats are absorbed from the intestine in the form of fatty acids and glycerol, *i.e.*, in the form in which they exist after the action of the lipase. That a resynthesis takes place in the epithelium is shown by the fact that as fat absorption goes on fat droplets are seen to grow in the protoplasm away from the free margin of the cells. As already mentioned, the fat is removed by the lacteals from the cells to the thoracic duct, and then to the general circulation. A small amount of the fat may pass into the body via the blood, but this is practically all retained by the liver. The amount of fat absorbed depends largely on the nature of the fat, especially with reference to its melting-point, fats of low melting-point being most readily taken up.

Protein. It is unquestionable in the light of modern work that the great bulk of the digested protein is absorbed from the intestine via the portal blood stream in the form of amino acids. The work of Abel with his vivi-diffusion apparatus demonstrated very clearly that amino acids circulated in the blood and the work of Folin and van Slyke demonstrated that the amino acids were taken up by the various tissues.

In the large intestine, little absorption of nutrient matter takes place under normal conditions, mainly of course because most of the absorbable material is removed whilst the food is in the small intestine. The principal substance absorbed here is water; and thus the excreta become firm and formed.

METABOLISM

Within the living protoplasmic mass of the tissue-cells activity is ceaseless. The whole series of changes has been given the name of metabolism and within this title are recognized the two phases of building up, *anabolism*, and of breaking down, *catabolism*. There is a constant interplay between these two phases, sometimes rapid, sometimes slow, with a straining towards an equilibrium which is never reached whilst life goes on. When this metabolism is analysed further it is customary to divide it into two parts, the metabolism of energy and the metabolism of matter or material. But it must be made clear that within the living cell metabolism is one and indivisible. Further, although for descriptive purposes it is necessary to discuss the metabolism of the different proximate principles, *e.g.*, protein, carbohydrate, etc., individually the fact must be appreciated that the living protoplasmic mass which forms the content of the cell is not a mere conglomerate of protein, carbohydrate, fat, salts and water, where each constituent may be envisaged as a separate entity. Protoplasm, on the contrary, is a complex colloid—an intimate compound of its various constituents. No constituent can be metabolized without influencing the metabolism of the others.

Protein.—After absorption the amino acids are taken up by the cells of the various tissues and would seem for the most part to undergo sooner or later a disintegrative change, deaminization, in which the amino group (NH_2), is broken off. It is commonly believed that the freed amino group is converted into ammonia (NH_3), which of course does not remain in the free state but becomes neutralized mainly by carbon dioxide to form ammonium carbonate. This ammonium carbonate in its turn is conveyed eventually to the liver, where it is finally transformed into urea and eventually excreted in the urine as a waste product. The nitrogen-free remainder is utilized for energy purposes either directly or indirectly. The work of Lusk and others has shown that under certain circumstances about 58% of the protein molecule can be converted into sugar. Such would seem to be the history of the fate of the bulk of the protein ingested. Of course a certain amount of the ingested material is not broken down in the way above described but is utilized intact by the organism as building material for the repair of tissue waste and for the formation of new tissue as in growth. Despite the variation in composition of the ingested proteins of a mixed diet the fact that all in the course of digestion are reduced to their simple amino-acid components serves a useful purpose in that it permits the various tissues, which have, of course, varying needs, to exercise a selective action over what they will retain and what reject. It is the composition of the tissues which determines the type of retention.

Evidence of the importance of the chemical composition of the protein fed has been had from another aspect which has shown definitely that the organism must receive certain, probably the majority, of its amino acids in the preformed state. Feeding experiments on young growing animals have been carried out where the protein fed was abnormal in that certain amino acids were completely absent. One of the proteins used was zein (from maize), which lacks the amino acids tryptophan and lysine. When young animals were fed on a well selected diet with zein as the sole protein they rapidly went downhill and died. When to the diet as before the appropriate amount of tryptophan was added to make good the deficiency in this amino acid, the animals remained alive but did not grow; when as a further addition lysine was added the animals not merely lived but grew.

Carbohydrate.—Carbohydrate may be regarded as the foodstuff which most readily gives up its energy in the organism. The tendency of modern work is to accept carbohydrate as *the* fuel. After absorption into the blood stream any excess above immediate requirements would seem to be deposited in the liver and muscles in the form of animal starch or glycogen as a readily available form of reserve. If there is a persistent over-ingestion the excess carbohydrate would seem to be converted into fat and thus there is built up a more permanent reserve of energy. Finally if the organism is suddenly flooded with sugar as the result of the ingestion of excessive amounts, much of the sugar is excreted as such in the urine—alimentary glycosuria. Normally the sugar is completely burnt in the organism to form carbon dioxide and water. The complete utilization of the sugar is intimately related to a special secretion of the pancreas to which the name of insulin has been given by its discoverers, Banting, Best, Macleod and Collip. When there is a disturbance of this insulin formation as in the disease known as diabetes, sugar is excreted as such in the urine, the body having lost the power to utilize it. Just how insulin acts is unknown. There is very good reason also, due primarily to the interesting work of Harden and Young on fermentation, to believe, certainly as regards muscle, that before the carbohydrate can be broken down it first enters into combination with phosphorus to form a hexose diphosphate.

Fat.—Fat is not apparently readily metabolized in the body, but it is not probably so stable as one might deduce from the apparent readiness with which it is deposited. It is undoubtedly, so to speak, invested capital, whereas carbohydrate may be looked upon as capital in current account or at most on deposit receipt. When combustion is carried out normally it is complete, the end

products being carbon dioxide and water. For this complete combustion it is essential that a certain amount of carbohydrate be present as is evidenced by the fact that when carbohydrate is withheld from the diet or when it is not available as in diabetes a condition known as acidosis ensues. In acidosis the combustion of fat ceases before combustion is complete, with the result that there is formed in the body and excreted in the urine β-hydroxybutyric acid, aceto-acetic acid and acetone. These substances can be caused to disappear from the urine if a supply of carbohydrate is made available. It would seem that there are two chemical actions involved in the breakdown of the long fatty acid chain, a special process of oxidation known as β-oxidation, associated with desaturation which renders the chain unstable. Although the evidence for the conversion of carbohydrate to fat is plain, there is still lacking indubitable evidence of the conversion of fat to carbohydrate, although many workers accept the idea.

Salts.—Although the mineral salts do not directly contribute to the supply of energy to the body and although generally speaking, they themselves undergo no metabolic change in the body they play a very important part in the various tissue activities. Unless the salts be present in proper amount and in proper proportion, metabolism is impossible. The principal mineral elements found in the body are sodium, potassium, calcium, magnesium, iron, phosphorus, sulphur, chlorine and iodine, with in addition traces of many other elements. Of course these various elements do not exist in the tissues in their free state but as compounds which, in the majority of instances, would seem to be inorganic. As all these substances are continually being lost from the body in the various excretions, it is essential that a sufficient supply be always available in the food. These mineral constituents play the main rôle in the maintenance of the faintly alkaline reaction of the various tissue fluids. As the result of the different metabolic processes which take place in the tissues there is a constant production of acid, chiefly from sulphur and phosphorus, which requires to be neutralized by basic elements like sodium and potassium and probably also calcium and magnesium. The kidney for the most part regulates in a very selective fashion the output of these various inorganic constituents. It must not be imagined, however, that the body can completely protect itself from excessive salt loss, a loss so great that it may give rise to symptoms of a serious character. Thus it has been shown that men who are, in the course of their work, exposed to high environmental temperatures with consequently much sweating, are very liable to a form of cramp. Further it has been noted that the cramp is frequently exacerbated where the men drink freely of water to allay their thirst. Recently it has been found that the condition is due to an excessive loss of sodium chloride from the body carried away in the sweat and that the condition may be cured or prevented by giving the men saline fluid to drink.

Although five-sixths of the total mineral matter of the body is found in bone and in spite of the fact that bone has all the appearance of being firm and resistant the evidence available goes to show that the bony structures must be regarded as active storehouses of mineral matter. When the need arises the body as a whole can draw upon the bones for constituents like lime and phosphates. Under certain conditions the bones indeed may give up so much of their mineral matter that they become soft and can no longer function as an effective frame work.

The other one-sixth of the mineral constituents found in the body are not distributed uniformly throughout the remainder of the tissues. As regards this varying distribution of salts in the tissues and the blood Macallum, in his study of palaeochemistry, produced some most interesting evidence in favour of his view that the present composition of the blood plasma, in so far as its inorganic constituents are concerned, is probably identical with that of the sea water just before the Cambrian period and that the salt concentration in protoplasm represents conceivably the salt concentration of the primaeval ocean in which life first appeared. At any rate the curious ratio of potassium and calcium to sodium, which is characteristic of protoplasm, is reflected in the salt relationship in water drawn from pre-Cambrian formations.

The mineral constituents play an important part without doubt in digestion in that acid must be secreted for gastric digestion and alkali for intestinal digestion.

Water.—In so far as water forms about 60% of the body-weight of man it is very obvious that the part it plays in metabolism must be an important one. It is indeed true that the whole series of chemical actions which are so intimately related to the life of the living organism, be it animal or vegetable, are ultimately referable to changes which take place in solution. It has been conclusively shown that the younger the animal the richer it is in water. It has also been found that the fatter the animal the smaller the percentage amount of water present.

So far as is known water undergoes no change in the body, but nevertheless all the water present in the organism does not come from some source external to the body but is in part formed in the tissues during the metabolism of the various foodstuffs and of the tissues themselves. According to one calculation this internal source of supply accounts for about 16% of the water excreted. It has been also maintained that this intracellularly formed water is of greater value to the living structure than the imbibed water as it presumably does not bring about drastic osmotic changes. It is impossible, however, with the information now available to decide whether the metabolic water in the cell differs in any way from the water received from external sources.

It is of interest to note that animals which live in arid regions, in contradistinction to those which live where water is abundant, excrete as their main nitrogenous waste product uric acid which is voided with the minimum waste of water instead of urea, which has to be excreted in solution.

Methods of Investigation.—Brief reference may here be made to the methods employed in investigating metabolism. No matter the line of attack selected, the investigator is handicapped by the fact that he can only deal with the end products of metabolic activity.

If the extent and degree of metabolic activity of a subject have to be determined we may do so by direct calorimetry. The subject is enclosed in a special chamber or calorimeter so devised that all the heat given off by the subject can be directly collected and measured (fig. 1). These calorimeters, which we owe mainly to the ingenuity and skill of Atwater, Rosa and Benedict, are very delicate and costly pieces of apparatus. In order that there be no escape of the body heat to the environment, the double copper walls of the chamber are fitted up with elaborate electrical equipment which permits of so delicate a balance that heat can neither pass out nor into the chamber. In order to measure the heat given off by the subject, a current of cold water is circulated within the box in continuous piping. If the temperature of the incoming and outgoing water is carefully measured and if the quantity of water passing through be also known the heat lost by radiation and conduction by the subject in a given time can be determined. As part of the heat lost, amounting to about one-fourth of the whole, is eliminated by the subject in the form of water vapour this must be and is also determined by absorbing the water lost in sulphuric acid and subsequent weighing of the acid container. This method of direct calorimetry is very accurate and reliable, but the method is difficult and the apparatus is very liable to get out of order. In addition to this direct measurement of the heat output, the metabolic activity of the subject

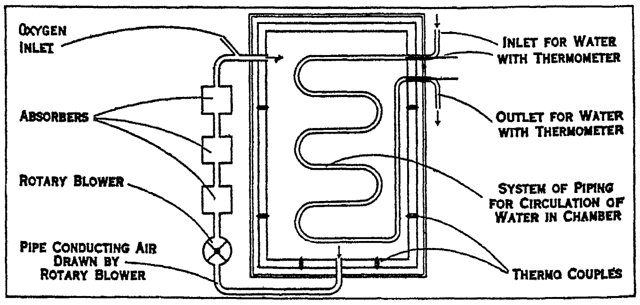

FIG. 1.—SCHEMA PRINCIPLES OF ATWATER-ROSA-BENEDICT RESPIRATION CALORIMETER

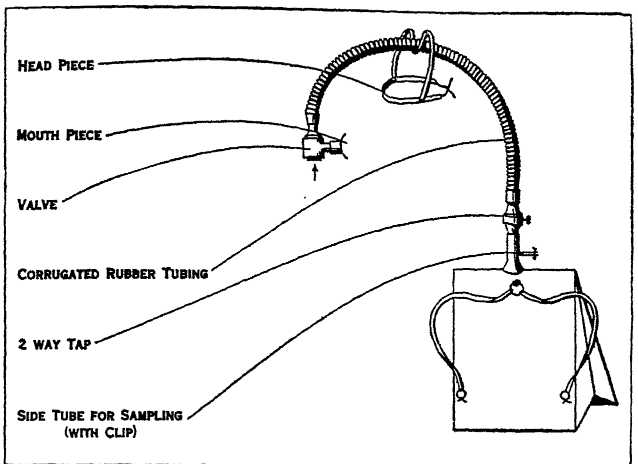
can be calculated from a determination of the amount of carbon dioxide given off and the amount of oxygen utilized by the subject in a given period. This method of Indirect Calorimetry can be carried out simultaneously with the direct method and serve as a check upon it. The calorimeter chamber in which the subject is enclosed is gas-tight and the air is circulated through a gas-tight absorbing system (fig. 1) by means of a rotary blower. The



FROM CATHCART, PATON AND PEMBREY, "PRACTICAL PHYSIOLOGY" (EDWARD ARNOLD & CO.)

FIG. 2.—INDIRECT CALORIMETRY: DOUGLAS BAG

carbon dioxide given off is absorbed by means of soda lime, the amount absorbed being determined by weighing the soda lime container at the beginning and the end of the experiment. The carbon dioxide free air is returned to the chamber after the deficiency in oxygen, which is approximately determined by reduction in volume, has been made good from a cylinder of pure oxygen. The amount of oxygen used during the experiment is determined either by measuring by a meter the amount of oxygen passed in or by weighing the cylinder before and after the experiment. The heat lost by the subject can be determined from the amount of oxygen used. The caloric value of a litre of oxygen used in the tissue combustion has been determined. This value varies with the carbon dioxide–oxygen ratio, called also the respiratory quotient (R.Q.), from 4·795 calories with an R.Q. of ·713 which is held to represent the combustion of fat alone to 5·058 calories with an R.Q. of 1·00, which is accepted as representing the combustion of pure carbohydrate by the tissues. The two methods of direct and indirect calorimetry have been found to give almost identical results.

It is obvious that the use of the chamber would act as a great handicap if the determination of energy expenditure were confined to it. To enable measurement of energy expenditure of subjects engaged in actual work a portable apparatus was first devised by Zuntz and later much simplified by Douglas (fig. 2). In this last form the subject wearing either a mask or special mouthpiece, with nose clip, fitted with two one-way valves breathes into a gas-tight bag carried on his back. The air collected in the bag at the end of the experiment is measured by passage through a meter, a sample of the expired air is analyzed in the Haldane gas analysis apparatus and the amount of carbon dioxide and oxygen present is determined. As the composition of the atmospheric air is known it is readily calculated how much carbon dioxide the subject excreted and how much oxygen is utilized in a given time and the caloric values can be determined as above. In order to relate the carbon dioxide output and oxygen utilization to the non-protein moiety of the food the protein metabolized during the period of the experiment is determined from the nitrogen output in the urine. For every gram of urinary nitrogen derived from protein 8·45g. of oxygen are required and 9·35g. of carbon dioxide are given off. Hence to determine the non-protein utilization the appropriate amounts of carbon dioxide and oxygen are deducted from the total amounts. As the amount of nitrogen excreted during the period of examination is minute, in practice it is usually ignored.

When the alterations of the gaseous metabolism are considered they are commonly referred to variations from the so-called Basal or Standard Metabolism. The basal metabolism may be defined as that of a subject lying comfortably at rest in a warm bed and in the post-absorptive condition, *i.e.*, about 12 to 15 hours after the last meal. With the subject in such a condition the metabolism reaches its lowest level. As it has been estimated that functional activities of the various organs may account for about 25% of the resting metabolism (thus the activity of the heart for about 3·6%, respiratory movements for about 10% and the kidney for about 5%) Krogh maintains that it is better to call this resting metabolism standard rather than basal. It, of course, could only be truly basal if all functional activities were in abeyance at the time of the determination.

It is obvious, in view of the fact that humanity is of varying sex and size, that if a universally applicable standard is to be obtained there must be some fundamental unit on which to base assessments. It has been shown that body-weight is not satisfactory. The modern unit selected is the surface-area of the body. A very useful formula for the determination of this area based on height $\times$ weight $\times$ a constant has been worked out by E. F. and D. Du Bois. As the result of their work it is common practice now to take as the fundamental unit the calorie output per square metre surface area.

This basal metabolism is shown to be high in childhood and that as adolescence is reached it falls to a level which is more or less uniformly maintained until about the age of fifty. Thereafter the decline is steady although small. The basal metabolism is also influenced by the sex of the subject, the nature of the food consumed, and environmental conditions like temperature, climate, etc. The most potent factor is, however, muscular work.

FACTORS WHICH INFLUENCE NORMAL METABOLISM

Fasting.—During fasting the body draws upon its own reserve of stored material for its requirements in the production of energy, and the rate of breakdown varies with the energy requirements. An individual kept warm in bed, therefore, stands fasting longer than one who is compelled to take exercise in a cold place. The breakdown of tissue during the early days of a fast is much greater than later, for as the fast progresses the body becomes more economical in its utilization of tissue. During a fast the tissues do not waste at an equal rate; those which are not essential are utilized at a much greater rate than those which are essential to the maintenance of the organism. For instance, it has been shown that during a fast the skeletal muscles may lose over 40% of their weight, whereas an essential organ like the heart loses only some 3%.

The essential tissues obtain their nourishment from the less essential by ferment action, a process which has been termed autodigestion or autolysis. The autolytic products of tissue digestion are practically identical with those which arise during the ordinary gastro-intestinal digestion.

Muscular Work.—The muscular tissue plays the most important part in general metabolism. Not only is muscle the most abundant tissue present, but it is constantly active and is the great energy-liberating machine of the body. Formerly it was believed on the authority of Liebig that muscular work was done at the expense of the protein material, but it has been conclusively shown that the real source of energy in moderate work is the non-protein material, carbohydrates and fats; of these the former plays the greater part in a man on ordinary diet. That there is some influence on protein is shown by the fact that there is a definite but small increase in the output of nitrogen in the urine as the result of muscular work, but it is in no sense proportionate to the work done; whereas the output of carbon dioxide produced by the combustion of the carbohydrates and of the fats is increased proportionately to the work done.

Internal Secretions.—Evidence is accumulating to show that the activities of the various tissues of the body are presided over and controlled not merely by the action of the nervous system but also by certain chemical substances elaborated in special glands known as endocrine glands or glands of internal secretion. The

active secretions of these glands are poured out into the blood stream. There is direct evidence that some of these secretions such as thyroxin from the thyroid gland and insulin from the pancreas exercise a very active influence on metabolism. In regard to the other secretions, more is known about their action on various tissues than of their direct influence on metabolism.

EXCRETION

While comparatively little is known of the intermediate stages in the breakdown of the food constituents, and more particularly of the protein moiety, knowledge of the final products of the metabolic changes excreted is fairly full. The urine is the main channel of excretion for the nitrogenous waste products. Water is excreted by the lungs, the kidneys and the skin.

The urine is a yellowish fluid which varies greatly in its depth of colour, from pale amber to a deep brown. It has a specific gravity of about 1020, varying with the percentage of solids in solution, and it usually has an acid reaction. Among the principal organic substances present are urea, ammonia, purines (uric acid and the so-called purine bases, xanthin, etc.), creatinine, conjugated sulphates, various aromatic bodies and many other substances in small amount, together with the water and inorganic salts.

The following table from Folin indicates the average composition of the urine in regard to the nitrogen-containing constituents, and its variation according to the nature of the diet when this is free of creatin, creatinine and the precursors of the purines.

	Nitrogen-rich diet	Nitrogen-poor diet
Total nitrogen	14·8–18·2g. per day	4·8– 8 0g. per day
Urea nitrogen	86·3–89·4% of total	62·0–80·4% of total
Ammonia nitrogen	3·3– 5·1% " "	4·2–11·7% " "
Creatinine nitrogen	3·2– 4·5% " "	5·5–11·1% " "
Uric acid nitrogen	0·5– 1·0% " "	1·2– 2·4% " "
Undetermined nitrogen	2·7– 5·3% " "	4·8–14·6% " "

Urea, which forms the chief nitrogenous constituent, amounting on an ordinary diet to about 30 g. per day, is for the most part formed in the liver, from ammonia obtained either directly from the blood after absorption from the intestine, or resulting from the deaminization of the amino acids.

Ammonia is present in the form of ammonium salts, and forms about 4% of the total urinary nitrogen. It may exceed this amount under certain conditions, for the most part pathological. The ammonia is utilized by the body to neutralize acids which arise during the various metabolic processes.

Purines (uric acid, xanthin, hypoxanthin, etc.) are all members of a series which have as their common nucleus a body which E. Fischer called purine. The most important member of this series is uric acid. It forms about 2% of the total urinary nitrogen. It has been shown that it has two quite definite sources of origin: (1) from ingested food containing the precursors, and (2) from the tissue-metabolism. The first is known as the exogenous source, and the second as the endogenous. This acid is chemically known as trioxypurine, and may be regarded as the union of two urea molecules with a three-carbon chain fatty acid. All the uric acid formed in the body is not excreted as such, part being, as already mentioned, converted into urea. The amount which is converted into urea varies with the species of animal. The other chief purine bodies present in urine are xanthin and hypoxanthin, purines less oxidized than uric acid; the first is a dioxypurine, and the second is a monoxypurine. The main source of total purine supply would seem to be muscle metabolism. The mother substances from which all are derived in the body are the nucleo proteins. These complex bodies are apparently first broken down by enzyme action to aminopurines. These in their turn have their amino groups split off, and then, according to the degree of oxidation, the different purine bodies are formed.

Creatinine. The physiological significance of this substance is as yet unknown. The daily excretion varies little with the character of the diet, provided, of course, that the diet be creatinine-free. It would seem to be derived from the creatine of muscle, a substance which is very readily changed into creatinine outside the body. Whatever its source, after urea and ammonia it is one of the important nitrogenous substances excreted.

Sulphur excreted in the urine comes chiefly from the sulphur of the protein molecule. It is excreted in various forms: (1) as the ordinary preformed sulphates, *i.e.,* sulphur in the form of sulphuric acid combined with the ordinary bases; (2) as ethereal sulphates, *i.e.,* in combination with various aromatic substances such as phenol, indol, etc.; (3) in the form of so-called neutral sulphur in such substances as cystin, which are intermediate products in the complete oxidation of sulphur.

Phosphorus appears linked to the alkalis and alkaline earths as phosphoric acid. A very small part of the phosphoric acid may be eliminated in organic combination such as the glycerophosphates, etc.

Sodium (mostly as sodium chloride), potassium, calcium and magnesium are the common bases present in the urine.

The lungs are the important channel of excretion for the waste product of carbon metabolism, carbon dioxide or CO_2 (*see* RESPIRATION); and also a very important channel for the excretion of water. In regard to the skin, the sweat carries off a large amount of the water. It has been estimated that about 900 c.c. are excreted each day under normal resting conditions, rising to 7,000 c.c. and over when hard work is done. Sweat contains salts, chiefly sodium chloride, and organic waste products. Of the organic solids excreted from this source, urea forms the most important under normal conditions.

Under pathological conditions, especially when there is interference with free renal action, the amount of nitrogenous waste excreted may become important.

NUTTING, MARY ADELAIDE (1858–1948), U.S. nurse educator, was born at Waterloo, Quebec, Canada, on Nov. 1, 1858. Educated in private schools, she became a member of the first class in The Johns Hopkins hospital school of nursing, Baltimore, of which school she was principal from 1894 to 1907, when she was given the chair of institutional administration at Teachers college, Columbia university, New York city. There in 1910 the first university department for the education of nurses was created and she was assigned to the chair of nursing and health. During World War I she was appointed by Pres. Woodrow Wilson chairman of the committee on nursing under the National Defense council. In 1920 the "Adelaide Nutting Historical Collection," showing the progress of nursing in the U.S. and other countries, was established in her honour at Teachers college. She retired in 1925.

With Lavinia Dock she wrote *A History of Nursing* and she was also the author of *A Sound Economic Basis for Schools of Nursing.* She died Oct. 3, 1948, in New York city.

NUX VOMICA, a poisonous drug, consisting of the dried ripe seed of *Strychnos nux-vomica,* a tree (Fam. *Loganiaceae*) indigenous to most parts of India, and found also in Burma, Thailand (Siam), Indochina and north Australia. The tree is of moderate size, with a short, thick, often crooked stem and ovate entire leaves, marked with three to five veins radiating from the base of the leaf. The flowers are small, greenish-white, tubular and arranged in terminal corymbs. The fruit is the size of a small orange, and has a thin hard shell, enclosing a bitter, gelatinous white pulp, in which from one to five seeds are vertically embedded. The seed is disk-shaped, about 1 in. in diameter, and $\frac{1}{4}$ in. thick, slightly depressed toward the centre, and in some varieties furnished with an acute keellike ridge at the margin. Externally, it is grayish-green and satiny from a coating of appressed silky hairs. Internally it consists chiefly of horny albumen, which is easily divided along its outer edge into halves by a fissure, in which lies the embryo. The latter is about $\frac{3}{10}$ in. long, and has a pair of heart-shaped membranous cotyledons.

The chief constituents of the seeds are the alkaloids strychnine (*q.v.*) and brucine, each of which constitutes from 1% to 2% of the dried seeds. The two have similar pharmacological actions though brucine is much less active.

NYACK, a village of Rockland county, New York, U.S., on the west bank of the Hudson river (which there expands into Tappan Zee, 3 mi. wide), 14 mi. above New York city. It is served by the Erie railroad, by buses and by a ferry to Tarrytown, nearly opposite. Pop. (1950) 5,889. With the adjacent villages of Upper Nyack, South Nyack, Central Nyack and West Nyack, the population exceeded 11,000 in 1950. The industries include shipyards, machine shops and several factories. Permanent settlement there dates from about 1700.

Nyack was incorporated in 1833 and was named after a tribe of Algonkin Indians.

NYANZA, the Bantu name for any water area of considerable size; especially applied to the great lakes of east Central Africa. The word is variously spelt, *e.g.*, Nyanja, and Nyasa.

NYASA, the third in size of the great lakes of Central Africa. It occurs south of the confluence of the two great rift valleys and extends from 9° 29′ S. to 14° 25′ S. The lake measures along its major axis, which is slightly inclined to the west of north, exactly 350 mi. while the breadth varies very little, the maximum being 45 mi. about the middle. The total area may be estimated at 11,000 sq.mi. The lake lies at an altitude of about 1,650 ft. above the sea. The sides of the valley in which Nyasa lies, which are somewhat irregular towards its southern end, take a decided character of parallel fault scarps in the northern third, and are continued as such beyond the northern extremity. The depth seems to vary between 200 and 430 fathoms, in accordance with the steepness of the shores. The lake receives its water-supply chiefly from the streams which descend from the mountains to the north, all the rest becoming very small in the dry season. Like other lakes of Central Africa it is subject to fluctuations of level, apparently caused by alternations of dry and wet series of years.

At the north-western end is a plain of great fertility, traversed by the Kivira, Songwe and other streams. On the delta of the Rukuru, is the British station of Karonga, the northern port of call for the lake steamers. Southwards the plain narrows, and the sandstone scarp of Mt. Waller rises sheer above Florence bay, the high western plateaux continuing to fall steeply to the water. At Cape Chirombo (11° 40′ S.) the coast bends to the west, and soon the plateau escarpments recede, and are separated from the lake along its southern half by an undulating plain of varying width, with Bandawe and Kota Kota ports on the coasts. A little north of the latter the Bua river, coming from a remote source on the upper plateau, enters by a projecting delta. At Domira bay the coast turns east, contracting the lake to a narrow neck, with Fort Rifu (west), and Fort Maguire, near Makanjira point (east). Beyond this the lake runs southwards into two bays separated by a granitoid peninsula, off which lie several small rocky islands. From the extremity of the eastern bay the Shiré makes its exit to the Zambezi. On the eastern side the escarpments and the boundary fault keep close to the lake, leaving few plains along its shores. In the north-east, the coast is formed by the unbroken wall of the Livingstone range (*q.v.*). On this coast is the station of Lumbira (Tanganyika Territory). The valley of the Ruhuhu, the only important stream which enters the lake from the east, breaks through the Livingstone range. The formation is here Karroo sandstone, corresponding to that of Mt. Waller on the opposite shore. Just north of the Ruhuhu is Manda, on an excellent harbour. To the south the wall of mountains recedes somewhat, and the remainder of the eastern shore shows a variation between rocky cliffs, marshy plains and low hills, to be followed farther south by a wide semicircular bay, generally rock-bound, and ending in Malo point, off which are the largest islands the lake possesses, Likoma and Chisamulu. In the southern half the coast is highest where the Mapangi hills rise to 3,000 ft.

Nyasa, reached in 1859 both by David Livingstone (from the south) and by the German, Albrecht Roscher (from the east), was explored by the former to about 11°, and to its northern end by E. D. Young in 1876. From this date onwards it has been the scene of much civilizing work on the part of British missionaries, traders and government officials, and of Germans also. Its shores are divided between Great Britain (with Tanganyika Territory and Nyasaland Protectorate) and Portugal (with Portuguese East Africa). British steamers, including gunboats, have been launched on Nyasa, which forms an important link in the water-route from the Zambezi mouth to the heart of the continent. The first detailed survey of its shores was executed by Dr. James Stewart (1876–1877), but this has been superseded by later work.

Bibliography.—A. R. Andrew and T. E. G. Bailey, "The Geology of Nyasaland," with note on fossil plants, fish remains, etc., by E. A. N. Arber and others and bibliography in vol. 66 of *Quart. Jnl. Geog. Society* (May 1910); Gen. J. C. Smuts, "East Africa," *Geogr. Journal* (1918); also Blue books and Colonial Office reports.

NYASALAND PROTECTORATE. Nyasaland covers rather more than 40,000 sq.mi., of which 37,374 are land. The country is situated between 9° 45′ and 17° 15′ S., and between 33° and 36° E. Its length from north to south is about 520 mi., while its width varies from 50 to 100 miles. It is bounded on the west by Northern Rhodesia and Portuguese East Africa, on the northeast by Tanganyika Territory, and on the east and south by Portuguese East Africa. The northern half of its eastern boundary is formed by Lake Nyasa.

Physical Features.—Nyasaland consists of elevated plateaus, sometimes separated by low-lying ground. The most important of these are the Nkonde mountains in the northwest, 6,000 to 7,000 ft. high, the Nyika plateau, rising to more than 8,000 ft., and the Angoniland plateau, whose highest points range between 5,000 and 6,000 ft., both of these plateaus being on the western side of the lake: the Mlanje massif, in the extreme southeast, mostly more than 6,000 ft., with several peaks rising above the general level, one attaining 9,843 ft., and the Shiré highlands between Lake Shirwa and the Shiré river, reaching, in their highest point, an elevation of 7,000 feet.

Lake Nyasa (*q.v.*), situated 1,650 ft. above sea level, receives a number of comparatively small rivers from the neighbouring highlands, and is drained southward by the Shiré river, which flows into the Zambezi. The lake has few good harbours, and is swept from time to time by violent northerly and southerly winds. Other large lakes are Lake Shirwa and Lake Chiuta, a sheet of water situated north of Lake Shirwa, and being 30 mi. long and from 2 to 8 mi. broad. The water of Lake Chiuta, like that of Lake Nyasa, is fresh.

Climate.—Three distinct climatic zones may be distinguished. In the low-lying Shiré valley the climate is hot, in October and November temperatures rising to 115° F. In the highlands, at an altitude of 3,000 ft. and above, extreme heat is unknown. Along the shores of Lake Nyasa the high degree of humidity makes the climate particularly trying to Europeans, although the temperature rarely rises above 95°. The dry season lasts from May to September, the weather being comparatively dry and cool. In higher mountain regions occasional frost may even occur during the night. The first rains, accompanied by violent thunder storms, set in after the middle of October and continue periodically until the end of December, when the season of heavy rains begins, lasting from January through March. The annual rainfall is about 50 in. in the highlands, 35 in. in the lowlands.

Vegetation.—Large tracts of the country are still covered with forest, especially away from the centres of European or native settlement. The forests are of little economic value, apart from their effect in checking rapid run-off and soil erosion. Most of the trees are small, the diameter of their trunks at about 4 ft. from the ground being usually from 4 to 12 inches. Timber trees of greater size and value are to be found in damp ravines on the mountain sides and along the banks of the rivers. The most important of these are the patches of Mlanje cypress (*Widdringtonia Whytei*), which yields a soft, durable wood, immune from the attacks of termites. These trees grow on the higher slopes of Mlanje mountain, and are not found elsewhere in Nyasaland. Two species of Brachystegia—Mombo and Nchenga—provide the natives with material for bark cloth and ropes. Tree planting is encouraged, and seeds are easily procurable of the Mlanje cypress, and of several kinds of eucalyptus, which is the most important

of the exotic trees.

Population.—In 1945 the population consisted of 2,044,707 Africans, 2,941 Asiatics, 1,948 Europeans and 455 other non-Africans. Almost half of the Europeans live in Blantyre (*q.v.*) and Zomba; the remainder are scattered widely in various parts of the protectorate. The average density is 55.66 persons per square mile, one of the most thickly populated areas in Africa. The native Africans belong to the Bantu and are composed of many ethnic groups of which the Nyanja, Nguru, Yao (*q.v.*) and Ngoni (or Angoni *q.v.*) are numerically the strongest.

Administration.—The protectorate is administered by a governor appointed by the crown. He is assisted by executive and legislative councils consisting of official and unofficial members. The principal departments of administration are in Zomba. Since March 1, 1945, the country has consisted of three provinces—Northern, Central and Southern—which are divided into three, seven and ten districts respectively. Provincial commissioners are in charge of the former; district commissioners supervise the latter. Towns are administered by town councils; that of Zomba is appointed by the governor, those of Blantyre and Limbe are elective. The native administration after 1933 followed the pattern of indirect rule, allowing African chiefs limited authority under the supervision of the district commissioners. In 1944 advisory councils composed of African chiefs were established in the provinces; these are designed to enable Africans to be more closely associated with the central administration.

Religion and Education.—The majority of the Africans are pagans; only 11% are classified as Christians and 10% as Moslems. Missionary activities are of long standing; the first mission opened near Zomba in 1861. Of the 11 missions which were active in 1940 the following may be mentioned: the Universities mission, the Livingstonia Mission of the Church of Scotland, the Church of Scotland mission, the Dutch Reformed Church mission, and the White Fathers. Education is primarily managed by missions which, in 1938, bore 65% of the expense. The education department assumed control in 1926. In 1942 there were four private schools for Europeans providing education to standard VI only, two schools for Asiatics and 4,171 primary schools for Africans with an enrolment of 173,692 children. Attendance is irregular, and few students complete the four-year course. Forty-seven vocational schools provide training for teachers; 453 men and 155 women were in training in 1941. Chief educational institution is the Jeanes Training Centre at Domasi.

Economy.—Agriculture is the chief occupation in Nyasaland. Besides maize and millet, which are the staple foods of the Africans, both European settlers and African natives grow tobacco, cotton and tea for export. The total tobacco production in 1942 was 24,800,000 lb.; in 1941 17,800,000 lb. were exported. Most of the tea is grown on European estates in the Mlanje district, but there are some plantations in the Cholo district. According to the international tea agreement (1938), Nyasaland agreed not to plant more than 17,700 ac. or produce more than 18,750,000 lb. for sale in the world's markets. The 1942 export was 5,600 short tons. Cotton production was developed gradually, chiefly among Africans, who exported more than 2,240 short tons in 1942. The production of tung oil is encouraged as an export crop; about 5,000 ac. were under cultivation in 1940, and in 1943 58,000 lb. were exported. Coffee production is insignificant. Livestock supply the needs for local markets. There has been an intensive search for minerals by the British South Africa company, holding the mineral rights for the country. The only prospect is the bauxite deposit in the Mlanje district, estimated as 67,200,000 short tons. Ten thousand natives engaged in fishing in Lake Nyasa and Lake Chilwa supply the local markets. Although the African is primarily an agriculturist working on his own farm, many have taken to wage earning. In 1937, 50,000 were seasonally employed in Nyasaland on European estates, while 100,000, or more than 18% of the fit adult population, had found employment outside the country, chiefly in Southern Rhodesia.

The value of exports in 1940 was £1,042,310; in 1941 it rose to £1,271,000; tobacco and tea accounted for more than 95%. Imports consisting of provisions, building material, agricultural implements, and textiles, were valued at £792,966 in 1940 and £1,004,000 in 1941; textiles accounted for more than 35% of the 1941 total. Nyasaland, falling under the Congo Basin treaties of 1885, cannot give a preference in its customs tariff to any state.

Wages in Nyasaland are low; unskilled labourers earn from 6*s.* to 10*s.* a month, domestic servants earn from 6*s.* to 30*s.* Special food allowances are normally provided.

Communications.—Nyasaland is connected with the port of Beira in Portuguese East Africa by a single track 3 ft. 6 in. gauge railway. In 1939 the Nyasaland railways extended from Salima via Chipoka and Blantyre to Port Herald (273 mi.) and connected via Sena and the Zambezi bridge (12,064 ft.) with Dondo in Portuguese East Africa. The railway was serviced by about 1,500 mi. of all-weather road (1938). On the lake was a regular service of ships, but river shipping on the Shiré lost its importance after the completion of the railway in 1935. Capital for the railway was acquired by involved series of loans (*c.* £5,000,000) which became the chief obstacle to the stabilization of Nyasaland's finances. Although the burden of the railway was largely shifted to the United Kingdom, the government insisted that the railway pay what it could, and therefore freight rates remained rather high, retarding the economic development.

(H. A. Wf.; X.)

History.—The first European who visited southern Nyasaland was Jasper Bocarro, who in 1616 carried samples of Zambezi silver from the vicinity of Tete to Malindi near Mombasa. During the next century Jesuit missionaries travelled through many sections of the country and brought back rumours of the existence of Lake Nyasa. The Lacerda expedition which penetrated as far as Lake Mweru in 1798 made the watershed of Lake Nyasa known, but the lake itself was not effectively discovered nor the country opened to Europeans until David Livingstone (*q.v.*) reached it on Sept. 16, 1859. In the following year the first attempt to establish missions was made, but it failed when a small group led by Bishop Mackenzie of the Universities Mission to Central Africa was decimated by fever and Yao hostility in the vicinity of Zomba. The region was, therefore, left to itself until the Livingstonia Free Church mission and the Church of Scotland mission were established in 1875–76. Since the missions found themselves unable to cope with the problems of supplying food and transport, the African Lakes corporation was formed in 1878. This corporation, nicknamed *mandala* (glass) by the natives because its founder, John Moir, wore spectacles, was the most important factor in opening Nyasaland.

The clashes between the missionaries and Arab slave traders brought the first British consuls into the country in 1883, and the African Lakes corporation enlisted volunteers in its unofficial war placed in 1888 under the command of Captain (later Lord) Lugard. At this time, the British government hesitated to interfere officially because Nyasaland was surrounded by Portuguese territory and remained inaccessible. A change in British attitude occurred in 1889, when D. J. Rankin discovered the navigable Chinde mouth of the Zambezi river, the status of which as an international waterway had been recognized in 1884. In the same year Cecil Rhodes' British South Africa company obtained a charter to develop Nyasaland. These developments inspired the British government to send Mr. (later Sir) H. H. Johnston into Nyasaland to negotiate treaties with the native chiefs and to thwart a Portuguese expedition under Major Serpa Pinto designed to link together the Portuguese territories of Mozambique and Angola. Between 1889 and 1891 British influence was consolidated, and as a result of the Anglo-German convention of 1890 and the Anglo-Portuguese convention of 1891, the Nyasaland Protectorate was established and was formally proclaimed in 1892. Johnston was put in charge of it as commissioner and consul-general responsible to the British Foreign Office. For five years he combined this post with that of administrator of the British South Africa company's trans-Zambezi territories which became Northern Rhodesia. With the aid of gunboats and Indian troops he suppressed slave raiding, forced Arabs and Yao into submission and subdued the Angoni, who had harassed the non-Angoni natives. The country was finally pacified in 1897. There

were then about 150 European settlers, nearly all in the vicinity of Blantyre and Zomba.

Sir Harry Johnston was succeeded as commissioner in 1897 by Sir Alfred Sharpe, whose intimate knowledge of the country was valuable in the work of development. The progress made was marked in 1904 by the transfer of the protectorate, up to that time under Foreign Office control, to the Colonial Office. In 1907 the title of the chief official was changed from commissioner to governor and in the same year executive and legislative councils were established. Called at first the Nyasaland Protectorate, the name was changed in 1893 to "The British Central Africa Protectorate," but in 1907 the old name was revived. When in 1910, Sir Alfred Sharpe retired, the urgent problems awaiting solution were economic; chief concern being over Nyasaland's communications with the sea, the river route having proved unsatisfactory. When World War I began, northern Nyasaland was invaded by Germans from East Africa. The governor, Mr. (later Sir) George Smith, was capable and energetic, and he received the full support of both Europeans and Africans.

There were 18,920 Africans recruited for service with the King's African Rifles, and 191,200 rendered seasonal service as carriers and noncombatants. The Germans were repelled, and later Nyasaland became a base for operations against them. There was, however, during the war, a disquieting incident. Among the natives were a number of professed Christians who claimed freedom from white control. One of these men, John Chelembwe, who had been educated in the United States, on his return built a church and preached the independence of Africans. With some 500 followers he rose in revolt in Jan. 1915. Three white settlers were murdered, one a Mr. Livingstone (a descendant of David Livingstone), and Chelembwe preached a sermon in his church with Mr. Livingstone's head placed on the pulpit. The revolt was speedily suppressed by a small force of British and natives, Chelembwe, who had taken to flight, and 20 of his followers were shot.

Following World War I, which brought German East Africa (renamed Tanganyika) within the British orbit, several attempts were made to amalgamate Nyasaland with adjacent British territories. While during the 1920s and 1930s Nyasaland's ties appeared to have been with Kenya and Tanganyika, after 1938 there was a movement to unite it to Northern Rhodesia. In 1939 the governor became a member of the East African Governor's conference as well as of the Inter-territorial conference at Salisbury, an assembly of the governors of Southern Rhodesia, Northern Rhodesia and Nyasaland. On Oct. 18, 1944 the British colonial office formally established a standing Central African committee to promote the closest contact and co-operation between the governments of the three territories. This council under the chairmanship of the governor of Southern Rhodesia held its first meeting in Salisbury, Southern Rhodesia, on April 24, 1945.

See S. S. Murray, *A Handbook of Nyasaland* (1932); *Annual Reports of the social and economic progress of the people of the Nyasaland Protectorate* (annually, British Colonial Office); *Yearbook and Guide of the Rhodesias and Nyasaland, 1938–39* (1939).

(H. A. Wf.; F. R. C.)

NYBORG, a seaport of Denmark on the island of Fyn, in the *amt* (county) of Svendborg. Pop. (1940) 8,994. The town was founded in the 12th century and a castle erected on Knudshoved (Canute's Head). From the 13th to the 15th century Nyborg was one of the most important places in Denmark. In 1658 it was held by the Swedes for about a year. The fortress, built by Christian IV. and Frederick III., was dismantled in 1869, and the ruins of the castle are used as a prison.

NYE, EDGAR WILSON (1850–1896), American humorist, was born at Shirley, Me., on Aug. 25, 1850. His parents removed to a farm on the St. Croix river in northern Wisconsin in 1852, and young Nye was educated in Wisconsin at the academy at River Falls, where he studied law. In 1876 he was admitted to the bar at Laramie, Wyo., where he served as justice of the peace, superintendent of schools, member of the city council and postmaster. Here he began to contribute humorous articles under the pseudonym of "Bill Nye" to newspapers, especially the Cheyenne *Sun* and the Denver *Tribune*. In 1881 he founded at Laramie the *Boomerang*, and his reputation as a humorist was soon widespread. Later he became a successful lecturer, and in 1885, with James Whitcomb Riley, the poet, made an extended tour through the country, each reading from his own writings. Nye removed to New York city in 1886, and passed the later years of his life at Arden, a village in North Carolina, where he died on Feb. 22, 1896. His principal books are *Bill Nye and Boomerang* (1881); *Forty Liars and other Lies* (1882); *Nye and Riley's Railway Guide* (1886), with James Whitcomb Riley; and two comic histories, *Bill Nye's History of the United States* (1894) and *Bill Nye's History of England from the Druids to the Reign of Henry VIII.* (1896).

See *Bill Nye, His Own Life Story, continuity* by F. W. Nye (1926).

NYIKA. This Swahili word means "forest and thorn bush country" and is used by the Swahili to designate a set of Eastern Bantu tribes, who during the 16th century under pressure from the Galla migrated down the coast from the steppes on the left bank of the Tana river. It does not include the Taita, Pokomo, Segeju and Akamba, though these are ethnically connected with the tribes to whom it is applied. The nine tribes included in the term Nyika are the Giryama, now living about 3° south of the Equator, the Rabai, the Duruma and the Digo—all upper Nyika tribes and the most important of the group: the other five are the lower Nyika—the Kauwa, Chonyi, Dzihana, Kambe and the Rihe or Ribe.

Generally speaking they are tall, muscular, well set up and broad-headed. The Digo, however, though well built are slender and have refined oval faces. There are evident affinities with the Northern Hamites, and their general colour is dark brown, becoming paler the nearer Mt. Kilimanjaro is approached. Waist clothes are worn by the men, and women wear many-pleated kilts, but are nude from the waist up, though now the tendency is to dress like Swahili women.

The *kaya* or fortified village was fundamental to their clan organization, but now that war is no longer anticipated, and villages are built outside the fortification, it has lost some of its significance, though still used for the assemblies of elders. The *kaya* is always situated on a hill or in a dense forest and is strongly palisaded. The Pokomo build circular huts like the Galla, but this group generally is characterized by rectangular huts, with a ridge-pole and a thatched roof extending to the ground and thus dispensing with walls. The houses are either gable- or hip-ended.

The Nyika tribes are divided into exogamous clans, which observe certain prohibitions and avoidances and share a general veneration for the hyaena in which all the cognate tribes join except the Pokomo: but now at any rate there is no trace of totemism. The clans of the Digo and Duruma are matrilineal; the rest are patrilineal with the exception of the Rabai, who are in a transitional stage. The Rabai have two sets of clans, male and female, and every man inherits the clan of his father and of his mother, but for all practical purposes he is reckoned as a member of his father's clan; a woman, on the other hand, while she similarly inherits both clans, stresses the mother's. Every clan has its own clubhouse (*lwanda*) and there is also the *moro* or council house, which is the general inter-clan meeting place for men, and houses the friction drum used for convening the council.

The Digo, probably under Arab influence, have hereditary sultans, but otherwise there are no paramount chiefs The government is in the hands of elders, who wear an ivory armlet as a badge of office. Every 13 years males have to be initiated at circumcision into an association analogous to Masai age-grades and after passing through the preliminary degrees they eventually reach the status of elders, among whom there is an inner circle called the Hyaena, which alone knows all the magical spells and consequently inspires great terror. From this circle are selected the "owners of the land," who carry on the government during the space of a *rika* or circumcision cycle.

The bow is the most usual weapon and the arrows are often poisoned. They also carry swords which are, however, as much implements as weapons. The Giryama have a parrying stick unique in the eastern area. Agriculture is carried on by women

who grow maize, millet, vegetables and sweet potatoes. They have sheep and goats but few cattle, and like most of the coastal tribes are careful not to take the cattle out till the heavy dew has dried from the grass, a precaution which does not seem to be necessary to the Bantu and Nilo-Hamitics living at higher altitudes.

The Nyika worship the typical Eastern Bantu deity *mulungu,* a vague abstraction of the sky combined with ancestor-worship with the main emphasis on the latter, the spirits of the dead (*koma*) surviving mortality and taking the world of the living under their charge. *Mulungu* is the dispenser and creator and from his union with the earth have sprung all things in the world including human beings, who are *mulungu's* hens and chickens. There are no professional rainmakers.

NYIREGYHAZA, the capital of the county of Szabolcs, in Hungary, is situated on the sandy loess Nyirseg plateau. It is an agricultural centre, specializing in the intensive cultivation of fruit and vines. There are also small manufactures, *e.g.,* of soda, soap and agricultural machinery. Pop. (1939) 56,108.

NYKÖPING, a seaport of Sweden, chief town of the district (*län*) of Södermanland, 98 mi. S.W. of Stockholm by a branch from the Stockholm-Malmö railway. Pop. (1943) 14,299.

Nyköping (*i.e.,* New-Market, Latinized as *Nicopia*) begins to appear as a town early in the 13th century. Its castle was the seat of the kings of Södermanland, and after those of Stockholm and Kalmar was the strongest in Sweden. It was burned by Albert of Mecklenburg's party in 1389, by an accidental conflagration in 1665, and by the Russians in 1719. Nyköping lies at the head of the Byfjord, an inlet of the Baltic. The ruins of its once famous castle, the town hall (1662), and the district governor's residence, are notable buildings.

NYMPH, in zoology, is the name given to the immature stages through which all insects with incomplete metamorphosis pass after leaving the egg. At its last moult the nymph gives rise to the perfect insect. (*See* INSECTS.)

NYMPHAEUM, a monument consecrated to the nymphs (*q.v.*), especially those of springs. These monuments were originally natural grottoes, which were traditionally considered the habitations of the nymphs. They were arranged to furnish a supply of water. Subsequently, artificial grottoes took the place of natural. The nymphaea of the Roman period were borrowed from the Hellenistic east (*e.g.,* The Great Nymphaeum of Ephesus). The majority were rotundas, adorned with statues and paintings. They served the threefold purpose of sanctuaries, reservoirs and assembly-rooms. A special feature was their use for the celebration of marriages. Such nymphaea existed at Corinth, Antioch and Constantinople; the remains of some 20 have been found at Rome and of many in Asia Minor, Syria and Africa. The term nymphaeum was also applied to the fountain in the atrium of the Christian basilica. (*See* FOUNTAIN.)

NYMPHS, in Greek mythology, the generic name of a large number of female divinities of inferior rank. The word, the etymology of which is uncertain, seems to mean simply a marriageable woman; this is appropriate, as they are mostly associated with fertile, growing things (as trees), or with water. They are frequently associated with the superior divinities, as Artemis, Apollo, Dionysus, Pan and Hermes (*q.v.*).

The nymphs were distinguished according to the different spheres of nature with which they were connected. Sea nymphs were *Oceanids* or *Nereïds,* daughters of Oceanus or Nereus. *Naiades* (from Gr. νάειν, flow, cf. νᾶμα, stream) presided over springs, rivers and lakes. *Oreades* (ὄρος, mountain) were nymphs of mountains and grottoes, one of the most famous of whom was Echo. *Napaeae* (νάπη, dell) and *Alseïdes* (ἄλσος, grove) were nymphs of glens and groves. *Dryades* (*q.v.*) or *Hamadryades* were nymphs of forests and trees.

In Italy they tended to be identified with native divinities of springs and streams (Iuturna, Egeria, Carmentis, Fons), while the Lymphae (originally Lumpae), Italian water-goddesses, owing to the accidental similarity of name, were identified with the Greek Nymphae.

O This letter, the fourth vowel of the modern alphabet, corresponds to the Semitic *ayin,* which represented not a vowel but a breathing. The Greeks, or possibly their Asianic predecessors, in adapting the Semitic alphabet to their own use used this letter (*omicron*) to express the vowel O, as was the case also with the letters *aleph, he, cheth* and *yodh.* Vowels were not expressed alphabetically in Semitic. The form of the letter on the Moabite stone was small, O, and this small form appears in early Greek inscriptions from Thera and Corinth. In Corinth and in the inscriptions from Abu-Simbel in Egypt there is a form ⬦. A form with a dot in the centre occurs in Thera, ⊙, and this is paralleled in the large Etruscan ⊙. At Miletus a form Ω occurs. The Latin form, taken from the Chalcidic or Etruscan, was O. The minuscule form retains the shape of the majuscule letter.

The Greeks used the letter to represent the short close vowel ŏ. For the long vowel they used a sign Ω (*omega*) probably adapted from O to one of the forms of which in use at Miletus it closely approximates. The western dialects used Ω to represent the long vowel, whether open or close. In the east it was used only for the open vowel, ου being used for the long close vowel as well as for the true diphthong. In the Cyclades however a reversal of this process frequently took place, Ω being used for the close sound whether long or short, O for the open. In Latin the letter stood for the same vowel without distinction of length, and the sound has passed almost unchanged into the Romance languages.

Classical Latin and onwards		O

THE DEVELOPMENT OF THE LETTER "O" FROM THE EARLIEST TIMES TO THE PRESENT DAY

In modern English the vowel has undergone changes. The long ō has become a diphthong (*ou*) as in the words *bone, rose.* Short ŏ has become more open and lower, as in *rob.* Before the consonant *r* the sound is rounded and pronounced very far back in the mouth, *e.g., glory, north.* In the word *do* the single letter is used where a more usual orthography would require its doubling. Again in the word *son* one would expect the vowel *u.* In words such as *word, work, world* the sound has been affected by the preceding bilabial. The short sound is the descendant of Middle English short ŏ in which both the close and open short ŏ, which were distinguished in Old English, met. The long ō, now a diphthong, descends from Middle English long ō, an open sound, which was derived from Old English long ā. In Middle English this was a rounded back vowel akin to the modern vowel in the words *shore, north.* Old English close long ō became in Middle English *oo* (ū). (B. F. C. A.)

OAK, the name given to trees and shrubs of the genus *Quercus* of the beech family (Fagaceae, *q.v.*), a large group which includes some of the world's most important timber trees. The oaks are widely distributed over the temperate parts of Europe, Asia, northern Africa and North America, and extend southward in mountains and highlands into the tropics. On the mountains of Europe and North America they grow only at moderate elevations and none approaches the arctic circle. The tendency of many species to vary in a marked degree and the existence of numerous hybrid forms make the determination of the exact number of species difficult, but it is estimated at from about 300 to upwards of 500.

The oaks are readily distinguished by their peculiar fruit, an acorn which consists of a nut partially or wholly enclosed in a cup composed of numerous involucral scales. The carpellate flower contains a single ovary, three-celled at first, but normally becoming one-celled and one-seeded by abortion. The staminate flowers are in small clusters on the usually slender and pendent stalk, forming an interrupted catkin. The alternate leaves are more or less deeply lobed or cut in many species, but in some of the deciduous and many of the evergreen forms are nearly or quite entire on the margin. The well-known *Q. robur,* one of the most valued of the oaks, and the most celebrated in history and myth, may be taken as a type for oaks with sinuated leaves. Though known in England, where it is the only indigenous species, as the English oak, it is a native of most of the milder parts of Europe and of the Caucasus mountains in Asia. More than 40 varieties are in cultivation in European nurseries and collections. The English oak is one of the larger trees of the genus, though old specimens are often more remarkable for the great size of the trunk and main boughs than for very lofty growth. The spreading branches have a tendency to assume a tortuous form, causing a zigzag development; to this peculiarity the picturesque aspect of ancient oaks is largely due. When standing in dense woods the trees are rather straight and formal in early growth, and the gnarled character traditionally assigned to the oak applies chiefly to its advanced age. The fruit matures in a single season. Vast oak forests still covered the greater part of England and central Europe in the earlier historic period. Many of the ancient oaks that remain in England may date from Saxon times; the growth of trees after the trunk has become hollow is extremely slow, and the age of such venerable giants is only a matter of vague surmise. The celebrated Newland oak in Gloucestershire, known for centuries as "the great oak," was 47½ ft. in girth at 5 ft. from the ground. The wood of the English oak, when grown in perfection, is one of the most valuable produced in temperate climates. The heartwood varies in colour from dark brown to pale yellowish-brown, is hard, close-grained and liable to split. The oak of Great Britain was formerly in great demand for the construction of merchant shipping. The fine-grained heartwood is sought by the

cabinetmaker for the manufacture of furniture, as are also the gnarled and knotted portions of slowly grown trees, which are sawn into veneers. Oak was formerly largely used by wood-carvers and was thus applied at a very early date; the shrine of Edward the Confessor, in the abbey at Westminster, was constructed of dark-coloured oak-wood.

The cultivation of this oak in Europe forms one of the most important branches of forestry. Its growth is slow, though it varies greatly in different trees; when grown for large timber oak can rarely be profitably felled until the first century of its growth is completed. It is often grown as an ornamental tree in the eastern United States, where, however, it is usually short-lived. In the southern parts of Australia and in New Zealand it seems to flourish as well as in its native home. An important product of oak woods is the bark, formerly the chief tanning material of Europe. The acorns of the oak possess a considerable economic importance as food for swine. In the Saxon period the "mast" seems to have been regarded as the most valuable product of an oak forest.

Of the European timber oaks, the next in importance to the English oak is *Q. cerris,* the Turkey oak of the nurserymen. This oak abounds all over the Turkish peninsula, on the Taurus ranges, and in many parts of southern Europe; it was introduced into England about 1735, and is common in parks and plantations.

The evergreen holly oak of southern Europe is *Q. ilex,* usually a small tree, frequently of rather shrub-like appearance, with abundant glossy dark-green leaves, more or less prickly at the margin. It abounds in all the Mediterranean countries. The bole sometimes grows 90 ft. in height, but it does not often reach a great size. In its native lands it attains a vast age; Pliny attributes to several trees then growing in Rome a greater antiquity than the city itself.

The cork oak, *Q. suber,* the bark of which yields cork (*q.v.*), is a native of the west Mediterranean area. In Spain the wood is of some value, being hard and close-grained, and the inner bark is used for tanning.

The valonia of commerce, one of the richest of tanning materials, is the acorn of *Q. macrolepis,* a fine species indigenous to Greece and the coasts of the Levant.

Some oaks are of indirect importance because of products formed by their insect enemies. Of these the Aleppo gall (*see* GALLS) is yielded by *Q. infectoria,* a native of Asia Minor and western Asia. *Q. coccifera,* a small bush growing in Spain and many countries around the Mediterranean, furnishes the kermes dye. (*See* KERMÈS.)

In North America the oaks are generously represented. They attain their greatest size and economic importance in the southern United States, especially in the lower Mississippi valley, and reach their maximum diversity as regards species in the highlands of Mexico, notably in the western Sierra Madre range, where they form vast forests. In *The American Oaks* (1925), W. Trelease enumerated 371 species, of which 253 occur in Mexico, 54 in Central America, 3 in Panamá, 4 in Colombia, and 1 in the Antilles (Cuba), while 84 are found in the United States, 10 extending into the southern border of Canada. These vary greatly in size from small, straggling or even creeping shrubs to magnificent forest trees, 150 ft. or more in height, with trunks exceeding 6 ft. in diameter. In addition, Trelease recognized more than 50 named hybrid oaks whose parent species are regarded as satisfactorily determined.

The American oaks fall into two main groups—the white oaks and the red or black oaks—about equal in number and comprising practically all the species. In the white oak group (*Leucobalanus*) the acorns ripen at the end of the first season, the shell of the nut is smooth inside, and the leaves or their lobes, which are usually rounded, are without bristle tips. In the black or red oak group (*Erythrobalanus*) the acorns ripen at the end of the second season, the shell of the nut is hairy inside, and the leaves or their lobes, which are usually sharp-pointed, are bristle-tipped.

Of the oaks found in the United States, upwards of 50 species attain the stature of trees, more than half of which are of economic value for timber or other useful purposes. Fully 20 species attain a height of 100 ft. or more, and 5 equal or exceed a height of 150 ft., with correspondingly massive trunks. These larger oaks constitute the chief supply of native hardwood lumber in North America. Three-fourths of them occur east of the Rocky mountains; the others are found in the Pacific states, chiefly in California, the quality of their timber in general being inferior to that of the eastern oaks.

Among the most valuable eastern white oaks are the typical white oak (*Q. alba*), 80 ft. to 100 ft. high, with a trunk 3 ft. to 4 ft. in diameter, one of the finest North American trees; the rugged and massive bur oak (*Q. macrocarpa*), sometimes 170 ft. high, with a trunk 6 ft. to 7 ft. in diameter; the chestnut oak (*Q. montana*), the post oak (*Q. stellata*), the overcup oak (*Q. lyrata*), and the swamp chestnut or basket oak (*Q. prinus*), all growing to a height of 100 ft. and highly valued for lumber. Noteworthy representatives of the eastern red or black oak group are the red oak (*Q. borealis*), sometimes 150 ft. high; the Shumard red oak (*Q. shumardi*), 120 ft. high; the black oak (*Q. velutina*), 150 ft. high; the somewhat smaller scarlet oak (*Q. coccinea*) and willow oak (*Q. phellos*), all important timber trees.

The oaks of the Rocky mountain region are mostly small trees, often becoming shrubby at the higher elevations. The Rocky mountain white oak (*Q. utahensis*), rarely 45 ft. high, is the largest Colorado oak, and the Arizona white oak (*Q. arizonica*), sometimes 60 ft. high, is the chief oak of New Mexico and Arizona.

In California some 15 species of oak occur. Among the deciduous forms are the valley oak (*Q. lobata*), often 100 ft. to 125 ft. high, sometimes with a massive trunk 10 ft. in diameter; the Oregon white oak (*Q. garryana*), 60 ft. to 100 ft. high, found from San Francisco bay to British Columbia, and the California black oak (*Q. kelloggii*), sometimes 100 ft. high, found also in Oregon. Among the evergreen species are the coast live oak (*Q. agrifolia*) and the interior live oak (*Q. wislizenii*), both medium-sized trees; the scrub oak (*Q. dumosa*), usually 2 ft. to 8 ft. high, abundant in the chaparral (*q.v.*), and the canyon live oak (*Q. chrysolepis*), sometimes growing erect to a height of 110 ft.

The only evergreen species of the eastern states is the live oak (*Q. virginiana*), found near the coast from Virginia to Texas; it grows to a height of 75 ft., usually branching near the buttressed base into a round-topped head, sometimes 130 ft. across. The very strong wood was formerly much used in shipbuilding.

The total cut of oak lumber in the United States in 1899 was 4,551,000,000 bd.ft., an all-time maximum. In 1940 the total cut was 1,467,000,000 bd.ft.; about one-third of this was cut in Virginia, Arkansas and Louisiana, the rest in 33 other states. Commercially, oak lumber is classified as white oak and red oak. White oak lumber is cut principally from the white, chestnut, post, bur, overcup and swamp chestnut oaks; red oak lumber is cut chiefly from the red, Shumard red, scarlet, black and willow oaks.

For world distribution *see* A. Engler and K. Prantl, *Die Natürlichen Pflanzenfamilien* (1887–1909); *see* also C. S. Sargent, *Manual of North American Trees* (2nd ed., 1922); W. Trelease, "The American Oaks," *Mem. Nat. Acad. Sci.* v, xx (1925); G. B. Sudworth, "Check List of the Forest Trees of the United States," *U.S. Dept. Agr. Mis. Cir. 92* (1927).
(F. W. J.; X.)

OAKDALE, a city of Allen parish, Louisiana, U.S.A., in the southwestern part of the state, on the Calcasieu river, and served by the Santa Fe and the Missouri Pacific railways. Pop. (1950) 5,598. Industries include manufacture of hardwood and pine lumber, furniture stock and naval stores.

OAKHAM, a market town, and the county town of Rutland, England, 90 mi. N. by W. of London by the London Midland Region railway. Pop. urban district (1951) 3,537; area 3.5 sq.mi. All Saints' church is chiefly Perpendicular. Of Oakham castle, first mentioned in 1151, the Norman hall (built 1190–1200) is little changed, and is used as the county hall. A custom prevails by which every peer of the realm on first passing through Oakham has to give a horseshoe (or a sum to buy one) to be placed in the hall.

OAKLAND, a city of California, U.S.A., on the mainland shore of San Francisco bay; connected with San Francisco by the 8¼ mi. San Francisco-Oakland bay bridge; the county seat of Alameda county and the third city of the state in size. It is a port

of call for numerous steamship lines and is served by the Santa Fe, the Southern Pacific and the Western Pacific and electric railways; by several air lines and by ferries and motor-coach lines. The population was 384,575 in 1950, in 1940 it was 302,163.

The business section of the city is built on a level crescent-shaped plain along the bay, averaging 3 mi. in width, behind which gently sloping hills rise to an elevation of 1,500 ft., providing residential sections with magnificent views of the bay, with San Francisco and the Golden Gate directly opposite. The land area of the city is 60.25 sq.mi. Adjoining it on the north is Berkeley; to the south, across an arm of the bay, is Alameda. These three cities and the five smaller municipalities of the metropolitan Oakland area (Emeryville, Piedmont, San Leandro, Albany and Hayward) had a population approximating 630,000 in 1950. In the heart of the city is Lake Merritt, a 160-ac. body of salt water and the only salt water lake in the heart of any American city.

After World War II the city undertook a vast program of building, including a civic centre at the south end of Lake Merritt. The University of California, in Berkeley, is only 4 mi. from the Oakland city hall. In Oakland, on a 60-ac. campus in the foothills, is Mills college for women, opened in 1871 by Cyrus T. Mills and Mrs. Mills.

Oakland has 19 mi. of water frontage in the port area. The estuary was dredged out to become a fine seaport bristling with docks, wharves, piers, ship-building cranes and ways. The railroads have solid filled moles and trestles extending from the shore into the bay. Much of the shallow bay front was filled in for additional industrial sites; the Oakland naval supply centre, the army base and the Alameda naval air station were almost entirely built on reclaimed land. The commerce of the harbour (including the Alameda side of the inner harbour) was approximately 4,000,000 tons annually at mid-20th century.

The industrial district lies just behind the water front, extending from Richmond on the north to Hayward in the south, and is traversed by many miles of main-line railroad trackage with spur-line facilities. After World War II, metropolitan Oakland had a great industrial expansion. Manufacturing plants in the metropolitan area obtain raw materials from nearby points, and minerals, petroleum, structural materials and other industrial materials are readily available. Agricultural products are funnelled in from southern Alameda county and adjacent communities for the many food-processing plants. Second only to the Los Angeles area in the Pacific coast production of automobiles and trucks at mid-century, the metropolitan Oakland area ranked first in the world in the production of calculating machines. Processed foods, canned goods, chemicals, electrical machinery, confectionery products, office equipment, paint and furniture were some of the other major industries.

The original site of Oakland was part of the holdings of Don Luis Maria Peralta, who received vast grants from the Spanish crown. In 1842 he divided his lands among his four sons, and the two to whom this region fell established themselves on their estates. From one of them in 1850 Moses Chase leased a tract, and he became the founder of the future city. In 1852 it was incorporated as a town, and in 1854 it was chartered as a city. In 1931 the city adopted a council-manager form of government. The name Oakland was suggested by the groves of oaks in which the first homes were built.

See E. J. Hinkel, *Oakland, 1852–1938* (1939).

OAKMONT, a residential and industrial borough of Allegheny county, Pa., U.S., on the Allegheny river and the Pennsylvania railroad, 12 mi. N.E. of Pittsburgh. Pop. (1950) 7,264; (1940) 6,260.

OAKMOSS, a lichen (*Evernia prunastri*) containing an oleoresin valued in perfumery both for its own fragrance of heavy, oriental type, and as a fixative base. Another species (*E. furfuracea*) having similar properties, is often included under the same common name, which is a translation of the French *Mousse de chêne*. Oakmoss grows on the trunks and branches of trees, also on poles and rails, in mountainous country throughout much of the northern hemisphere, in pale, greenish gray tufts 2 or 3 in. long, extending or drooping, made up of flattened strands which fork repeatedly, ending in pointed tips. The upper or outer surface of these strands is minutely warty and dusted with pale gray soredia, particles which reproduce the plant in the absence of the rare, disk-shaped, sexual fruit bodies (apothecia). The under surface is whitish, channeled in a faint, net-like pattern. Other lichens of the genera Usnea, Ramalina, Parmelia, etc., which grow intermingled with the Evernia, frequently gathered with it in the commercial product, have little fragrance, but may contribute to the value of the oleoresin as a base. Chief sources of oakmoss from about 1900, when the perfume first came into general use, until 1940, were Yugoslavia and France, large quantities being shipped for distillation in northern Europe. After the disruption of trade by war conditions, investigation showed the lichens to exist in Canada and northern United States, and they have been distilled in America to a limited extent. Oakmoss was used in perfumery as early as the 16th century, later forgotten. Baskets filled with it have been found in the ancient royal tombs of Egypt, but whether intended for perfume or, as some suggest, for making bread, is not known. It contains a starchy substance undoubtedly edible.

OAKMOSS (EVERNIA PRUNASTRI). AFTER "THE LICHEN BOOK"

OAK PARK, a village of Cook county, Illinois, U.S.A., 9 mi. W. of Chicago's loop. It is served by the Chicago and North Western, the Chicago, Aurora and Elgin, and the Baltimore and Ohio Chicago Terminal railways. Pop. (1950) 63,529. Assessed valuation of property in 1949 was $161,196,453. The village was incorporated in 1901.

OANNES (also Iannes, Euahanes), in Babylonian mythology, the name given by Berossus to a mythical being who taught mankind wisdom. He is identical with the god Ea (*q.v.*), although there may not be any direct connection between the two names. Berossus describes Oannes as having the body of a fish but underneath the figure of a man. He is described as dwelling in the Persian gulf (Erythraean sea) and rising out of the waters in the daytime and furnishing mankind instruction in writing, the arts and the various sciences. Other epithets of Oannes are Annēdotus, Odakōn, Euedokus, Eneugamos, Eneuboulos, Anēmentos. This antediluvian myth of a fish-like monster is based on the water god Enki of Eridu, patron of wisdom, symbolised as a "goat fish," and identified with Capricorn. (S. L.)

OARFISH, an oceanic fish, *Regalecus,* characterized by the long, compressed body, short head, large eye and long dorsal fin forming a crest on the top of the head. The oarfish is distinguished from its allies, the dealfishes (*q.v.*) by the long filamentous pelvic fins ending in a spatulate expansion (hence their name). These fish reach a length of nearly 40 ft.

OASIS, a fertile spot surrounded by desert (the Greek form is αὔασις which is doubtfully referred to the Coptic word *ouahe,* a dwelling place). On the desert Libyan plateau immediately west of the Nile between Aswan and Cairo are areas where the water comes to the surface or is found in shallow wells, *e.g.,* Oases of Khârga, Dâkhla and Farâfra. The water may come to the surface in springs, upon the artesian principle, or it may collect and remain in mountain hollows. These areas vary considerably in extent; they are always intensively cultivated and support thick growths of date-palms; and all kinds of tropical vegetables, grains and small fruits are grown. Some oases have a large population with substantial dwellings, others are merely halting-places.

OASTLER, RICHARD (1789–1861), English reformer, was born at Leeds on Dec. 20, 1789, and in 1820 succeeded his father as steward of the Thornhills' extensive Fixby estates at Huddersfield, Yorkshire. In 1830 John Wood, a Bradford manufacturer, called Oastler's attention to the evils of child employment in the factories of the district. Oastler at once started a campaign against the existing labour conditions by a vigorous letter, under the title "Yorkshire Slavery," to the *Leeds Mercury.* After many years of agitation, in which Oastler played a leading part, the Ten

Hours bill and other Factory acts were passed, Oastler's energetic advocacy of the factory-workers' cause procuring him the title of "The Factory King." In 1838, however, owing to his opposition to the new poor law and his resistance of the commissioners, he had been dismissed from his stewardship at Fixby; and, in 1840, being unable to repay £2,000 which he owed his late employer, Thomas Thornhill, he was sent to the Fleet prison, where he remained for over three years. From prison he published the *Fleet Papers,* a weekly paper devoted to the discussion of factory and poor-law questions. In 1844 his friends raised a fund to pay his debt, and on his release he made a triumphant entry into Huddersfield. Oastler died on Aug. 22, 1861.

See W. R. Croft, *The History of the Factory Movement, or, Oastler and his Times* (1888).

OATES, TITUS (1649–1705), English conspirator, was the son of Samuel Oates (1610–1683), an Anabaptist preacher, chaplain to Pride, and afterwards rector of All Saints' church, Hastings. On leaving Cambridge he took Anglican orders, and officiated in several parishes, Hastings among them. Having brought malicious charges in which his evidence was rejected, he narrowly escaped prosecution for perjury. He next obtained a chaplaincy in the navy, from which he was speedily dismissed. He now applied for help to Dr. Israel Tonge, a rector who was obsessed with the idea of Roman Catholic plots; Oates was to help him in unravelling the plots. To this end it was decided that Oates should pose as a Catholic. He spent some time at the Jesuit colleges of Valladolid and St. Omer, being expelled from both.

Returning in June 1678 to Tonge, he forged a plot by piecing together things true and false, or true facts falsely interpreted, and by inventing treasonable letters and accounts of preparations for military action. The whole story was written by Oates in Greek characters, copied into English by Tonge, and finally told to one of Charles II's confidential servants named Kirkby. Kirkby having given the king his information, Oates was sent for. He gave details, in 43 articles, of the plot and the persons who had engaged to assassinate Charles. Charles at no time believed this incredible farrago. To bolster up the case a fresh packet of five forged letters was concocted; but the forgery was transparent, and even Sir William Jones, the attorney-general, though a violent upholder of the plot, dared not produce them as evidence.

Oates now made an affidavit before Sir Edmond Berry Godfrey (*q.v.*) to an improved edition of his story, in 81 articles. Among the persons named was Coleman, secretary to the duchess of York, whom Godfrey knew, and to whom he sent word of the charges. Coleman in turn informed the duke, who induced Charles to compel Oates to appear before the privy council. Here Oates was exposed by a few simple questions. But among the papers seized at Oates's request were Coleman's, and in them were found copies of letters written to Père la Chaise, suggesting that Louis should furnish him with money, which he would use in the French and Catholic interest among members of parliament. Among them, too, were these passages: "Success will give the greatest blow to the Protestant religion that it has received since its birth"; "we have here a mighty work upon our hands, no less than the conversion of three kingdoms, and by that perhaps the utter subduing of a pestilent heresy, which has so long domineered over great part of the northern world." The credit of Oates was thus, in the eyes of the people, re-established, and Coleman and others named were imprisoned.

On Oct. 12, occurred the murder of Godfrey. On Oct. 21, parliament met, and Oates was called before the house. A new witness was wanted to support Oates's story, and in November a man named William Bedloe came forward. At first he remembered little; by degrees he remembered everything that was wanted. Oates then accused the queen before Charles of high treason, and carried his tale before the house of commons. The commons voted for the queen's removal from court, but, the lords refusing to concur, the matter dropped. It was not, however, until 1679 that the slaughter of Jesuits and other Roman Catholics upon Oates's testimony and that of his accomplices was checked. Sir George Wakeman, the queen's physician, was accused of purposing to poison the king, and the queen was named as being concerned in the plot. Sir Philip Lloyd proved Oates to have perjured himself, and Wakeman was acquitted. On June 26, 1680, upon Oates's testimony, the duke of York was presented as a recusant at Westminster. But the panic had worn itself out, and Oates retired on a pension. Shortly before the death of Charles, James brought, and won, a civil action against Oates, with damages of £100,000; in default of payment Oates was taken to prison; while there he was indicted for perjury, and was tried in May 1685, soon after the accession of James II. He received a severe sentence with repeated floggings, which was expected to kill him, but to the astonishment of all he survived.

Oates was in prison for three and a half years. Finally he received a royal pardon, with a pension of £300 a year. The remainder of his life was spent in retirement, varied by sordid intrigue. In 1691 he became acquainted with William Fuller, whom he induced to forge another plot, though not with the success he had himself attained. In 1696 he dedicated to William III a book called *Eikon Basilike,* a tissue of invective against "the late king James." In 1698 he obtained admission as a member of the Baptist Church, and used to preach at Wapping; but in 1701, as the result of a financial scandal, he was formally expelled from the sect. He died on July 12, 1705.

On the question of the place of his education see *Notes and Queries* (Dec. 22, 1883). *See* also T. Seccombe's essay in *Twelve Bad Men* (1894, bibliography).

OATH (O.Eng. *âdh*), an asseveration or promise made under non-human penalty or sanction. The word is found throughout the Teutonic languages, but without ascertainable etymology.

Retribution for Violation (*see* DYNAMISM).—The harm or penalty consequent on perjury may be considered to result directly, without any spirit or deity being mentioned. Thus among the Nagas of Assam, two men will lay hold of a dog or a fowl by head and feet, which is then chopped in two with a single blow of the dao, this being emblematic of the fate expected to befall the perjurer. Or a man will take hold of the barrel of a gun, a spear-head or a tiger's tooth, and solemnly declare, "If I do not faithfully perform this my promise, may I fall by this!" (Butler in *Journ. Asiatic Soc., Bengal,* 1875, p. 316).

In Siberia, in lawsuits between Russians and the wild Ostiaks, it was usual to bring into court the head of a bear, the Ostiak making the gesture of eating, and calling on the bear to devour him in like manner if he does not tell the truth. Similar oaths are sworn on the head or skin of a tiger by the Santals and other indigenous tribes of India. Death by a tiger precludes reincarnation and therefore involves social and physical extinction. Both in the old and modern world oaths by rivers are most sacred. In earlier ages men swore inviolably by Styx or Tiber, and an oath on water of the Ganges is to the Hindu the most binding of pledges, for the goddess will take awful vengeance on the children of the perjurer. The Tungus brandishes a knife before the sun, saying, "If I lie may the sun plunge sickness into my entrails like this knife."

The transition to invoking gods conceived in human form is shown in the treaty-oath between the Macedonians and the Carthaginians recorded by Polybius (vii 9); here the sun and moon and earth, the rivers and meadows and waters, are invoked side by side with Zeus and Hera and Apollo, and the gods of the Carthaginians. The heaven-god, able to smite the perjurer with his lightning, was invoked by the Romans, when a hog was slain with the sacred flint representing the thunderbolt, with the invocation to Jove so to smite the Roman people if they broke the oath (Liv. i 24; Polyb. iii 25). But bears and tigers are as apt to kill truth-tellers as perjurers, and the lightning-flash falls without moral discrimination. In the *Clouds* of Aristophanes, the Socrates of the play points out that notorious perjurers go unharmed, while Zeus hurls his bolts at his own temple and the tall oaks, as if an oak-tree could perjure itself.

The doctrine of miraculous earthly retribution on the perjurer

lasted on in legend, as where Eusebius relates how three villains conspired to bring a false accusation against Narcissus, bishop of Jerusalem, which accusation they confirmed by solemn oath before the church, one wishing that if he swore falsely he might perish by fire, one that he might die of the pestilence, one that he might lose his eyes; a spark no man knew from whence burned to ashes the first perjurer's house and all within, the second was consumed by the plague from head to foot, whereupon the third confessed the crime with tears so copious that he lost his sight (Euseb. *Hist. Eccl.* vi 9). In general the supernatural retribution on perjury has been transferred to beyond the grave.

International Forms.—Gestures such as grasping hands, or putting one hand between the hands of another in token of homage, are not oaths, but ceremonies of compact. Even the covenant among many ancient and modern nations by the parties mixing their blood or drinking one another's is in itself only a solemn rite of union, not an oath proper.

The act of swearing by weapons may signify that the swearer if forsworn is to die by such a weapon; or the warrior may appeal to his weapon as a powerful or divine object (*see* Du Cange, *s.v.* "Juramenta super arma"; Grimm, *Deutsche Rechtsalterth.*, p. 896). Stretching forth the hands towards the object or deity is a natural gesture, used by Israelites (Gen. xiv 22; Deut. xxxii 40; *see* Dan. xii 7; Rev. x 5). In France a juror takes oath by raising his hand, saying, "Je jure!" The Scottish judicial oath is taken by the witness holding up his right hand uncovered, and repeating after the usher, "I swear by Almighty God, and as I shall answer to God at the great day of judgment, that I will," etc.

In the ancient world sacrifice (*q.v.*) often formed part of the ceremony of the oath; typical examples may be found in the Homeric poems. Details of the old Scandinavian oath have been preserved in Iceland in the Landnámabók (*Islendinga Sögur*, Copenhagen, 1843); a bracelet (baugr) of two rings or more was to be kept on the altar in every head court, which the godi or priest should wear at all law-things held by him, and should redden in the blood of the bullock sacrificed, the witness pronouncing the remarkable formula: "Name I to witness that I take oath by the ring, law-oath, so help me Frey, and Niörd, and almighty Thor" (hialpi mer svâ Freyr, ok Miördr, ok hinn almâttki Âss), etc. This was doubtless the great oath on the holy ring or bracelet which the Danes swore to King Alfred to quit his kingdom.

Under Christ's injunction, "Swear not at all" (Matt. v 34; also James v 12), many Christians have shrunk from taking oaths, *see* writings of the Fathers. In more modern times Anabaptists, Mennonites and Quakers have refused to take even judicial oaths. On the other hand, the laws of Christendom from early ages have been directed against such swearing as was considered profane or otherwise improper, and against perjury. Constantine's laws required every witness in a cause to take oath; this is confirmed in Justinian's code which even in some cases requires also the parties and advocates to be sworn (*Cod. Theod.* xi 39; *Justin. Cod.* iv 20, 59). Bishops and clergy were called upon to take oath in ordination, monastic vows, and other ecclesiastical matters (*see* details in Bingham, *Antiq. of Chr. Church,* xvi 7). The Reformation conformed to this principle in Art. xxxix of the church of England. The Christian oath on a copy of the Gospels seems derived from the late Jewish oath taken holding in the hand the scroll of the law (or the phylacteries), a ceremony itself possibly adapted from Roman custom (*see* treatise "Shebuoth" in *Gemara*). The practice of kissing the book, established in England, appears in the middle ages (J. E. Tyler, *Oaths,* pp. 119, 151). The book was often laid on the altar, or the swearer laid his hand on the altar itself, or looked towards it; or touched relics of saints on the altar. Other objects, as the cross, the bishop's crosier, etc., were sworn by (*see* Du Cange, *s.v.* "Jurare"). An oath ratified by contact or inspection of a sacred object was called a "corporal" or bodily oath, as distinguished from a merely spoken or written oath.

Oath Formulas.—Among the oath formulas used in Christendom, that taken by provincial governors under Justinian is typical of one class: "I swear by God Almighty, and His only begotten Son our Lord Jesus Christ, and the Holy Ghost, and the Most Holy Glorious Mother of God and ever Virgin Mary, and by the Four Gospels which I hold in my hand, and by the Holy Archangels Michael and Gabriel," etc. The famous oath of the kings Louis and Charles at Strassburg in A.D. 842 runs: "By God's love and the Christian people and our common salvation, as God shall give me knowledge and power," etc. In the oath of fealty in the capitularies of Charlemagne in 802 is found the familiar form "Sic me adjuvet Deus," corresponding to formulas of pre-Christian Rome. This became widely spread in Europe, appearing in Old French "Si m'ait Dex," German "So mir Gott helfe," English "So help me God." A remarkable point in its history is its occurrence in the "So help me Frey," etc., of the old Scandinavian ring-oath already described. William the Conqueror swore "by the splendour of God," Richard I "by God's legs," John "by God's teeth"; other phrases are given in Du Cange as "per omnes gentes," "per coronam," "par la sainte figure de Dieu," "par la mort Dieu," etc.

Law.—In England the coronation oath is administered by an archbishop or bishop in the presence of the people, who, on their parts, reciprocally take the oath of allegiance to the crown. *The archbishop or bishop shall say:* "Will you solemnly promise and swear to govern the people of this United Kingdom of Great Britain and Ireland and the dominions thereto belonging according to the statutes in parliament agreed on, and the respective laws and customs of the same?" *The king shall say:* "I solemnly promise so to do." *Archbishop or bishop:* "Will you to the utmost of your power cause law and justice, in mercy, to be executed in all your judgments?" *King:* "I will." *Archbishop or bishop:* "Will you to the utmost of your power, maintain the laws of God, the true profession of the Gospel, and the Protestant reformed religion established by law? And will you maintain and preserve inviolably the settlement of the Church of England and the doctrine, worship, discipline and government thereof, as by law established in England? And will you preserve unto the bishops and clergy of England, and to the churches therein all such rights and privileges as by law do or shall appertain to them, or any of them?" *King:* "All this I promise to do." *After this the king, laying his hand upon the holy Gospels, shall say:* "The things which I have here before promised I will perform and keep; so help me God," *and then shall kiss the book.* (*See* CORONATION.)

The chief officers of state take an "official" oath well and truly to serve his majesty. Special oaths are taken by privy councillors, archbishops and bishops, peers, baronets and knights, recruits and others. The old oath of allegiance, as administered (says Blackstone, *Commentaries,* book i chap. x) upwards of 600 years, was replaced in the reign of William III by a shorter form; and it now runs: "I . . . do swear that I will be faithful and bear true allegiance to His Majesty . . . , his heirs and successors, according to law." Statutes of Charles II and George I enacted that no member should vote or sit in either house of parliament without having taken the several oaths of allegiance, supremacy and abjuration. In modern times a single parliamentary oath was substituted for the three, and this was altered to enable Roman Catholics to take it; Jews were enabled to sit in parliament by being allowed to omit the words "on the true faith of a Christian." In its present form the parliamentary oath consists of an oath of allegiance and a promise to maintain the succession to the crown as limited and settled in the reign of William III. The right to affirm in lieu of taking the parliamentary oath was first raised in the case of Charles Bradlaugh (*q.v.*). The "judicial" oath taken by judges of the court of appeal or of the High Court of Justice, and by justices of the peace is "to do right to all manner of people after the laws and usages of this realm, without fear or favour, affection or ill-will." Jurors are sworn, whence indeed their name (*iuratores*); in felonies the oath administered is: "You shall well and truly try and true deliverance make between our sovereign lord the king and the prisoner at the bar whom you shall have in charge, and a true verdict give according to the evidence." (*See* PRACTICE AND PROCEDURE: *Juries.*) The oath of the jurors in the Scottish criminal courts is: "You [the jury collectively] swear in the name of Almighty God and as you shall answer to God at the great day of judgment that you will truth say and no truth conceal in so far as you are to pass upon this assize." In the ancient

custom of compurgation, once prevalent in Europe, the accused's oath was supported by the oaths of a number of helpers or compurgators who swore to their belief in its validity.

Witnesses in English law courts must give their evidence under the sanction of an oath, or of what is equivalent to an oath, and the ordinary form of oath adapted to Christians is: "The evidence you shall give . . . shall be the truth, the whole truth, and nothing but the truth. So help you God." Many alterations of the English law as to oaths have been made in relief of (1) those Christians who object on conscientious grounds to the taking of an oath, and (2) of those persons who refuse to admit the binding force of an oath. Special provision was first made for Quakers, Moravians and Separatists; then followed general enactments relating to civil and criminal proceedings respectively, till finally the law was embodied in the Oaths Act 1888, which enacted that "every person upon objecting to being sworn, and stating, as the ground of such objection, either that he has no religious belief, or that the taking of an oath is contrary to his religious belief, shall be permitted to make his solemn affirmation instead of taking an oath." . . . The form of affirmation prescribed by the Oaths Act was as follows: "I, *A. B.*, do solemnly, sincerely, and truly declare and affirm," etc. Under s. 5 of the same act a person might swear in the Scottish form, with uplifted hand (no book of any kind being used) and if he desired to do so "the oath shall be administered to him in such form and manner without question." With the desire of making universal the method of administering the oath the Oaths Act 1909 was passed. A Christian swears on the Gospels, holding a copy of the New Testament in his uplifted right hand, the hand being uncovered, and his head being also uncovered. A witness may elect to be sworn on any version of the Bible which he considers most binding on him, as a Roman Catholic on the Douai Testament or Bible. A Jew is sworn on the Pentateuch, holding a copy thereof in his right hand, the head being covered. A Mohammedan is sworn upon the Koran. He places his right hand flat upon the book and puts the other hand upon his forehead, bringing his head down to the book and in contact with it. He then looks at the book for some moments. Buddhists are sworn on the Buddhist doctrines, Sikhs upon the Granth, Parsees upon the Zend Avesta, Hindus upon the Vedas, or by touching the Brahmin's foot, and, according to caste custom, Indian witnesses sometimes insist upon the oath being administered by a Brahmin; but in India witnesses now generally affirm. Kafir witnesses swear by their own chief, and a Kafir chief by the king of England. When a Chinese witness is to be sworn, a saucer is handed to him which he takes and, kneeling down, breaks into fragments.

The administering or taking of unlawful oaths is criminal in English and Scots law. Statutes relating to the offense were passed in 1797, 1799, 1810 and 1812, and it is evident from the preamble of the latter act (Unlawful Oaths Act 1812) that they were aimed at those societies in the United Kingdom at the time of the French Revolution which required or permitted their members to take an unlawful oath. Supplementary statutes were passed in 1817 and 1837. Children of tender years, who, in the opinion of the court, have not sufficient intelligence to understand the nature of an oath, may give evidence without being sworn.

United States.—In the United States oaths required by way of qualification for public office or citizenship are generally prescribed by constitutions or statutes. At an early date provisions were made for simple affirmation for the benefit of those whose religious faith proscribed the taking of an oath. Witnesses in the law courts or before legal or administrative officials invested with the power of administering oaths must give their evidence under oath or by affirmation. Belief by the witness in a God and an appeal to Him as an avenger of falsehood are the essentials of the oath. Liberal allowances may thus be made for the taking of oaths by non-Christians, the witness being sworn in such fashion as he considers binding on his conscience. Professed atheists have on occasion been excluded from the witness stand, but generally the religious belief of a witness can only be used to impeach his credibility. No special form need accompany the administration of an oath, unless required by statute, provided that some formal act be done to impress the witness with the distinction between sworn statements and bare assertions.

OATS. The oat plant belongs to the genus *Avena* and is one of the more important cereal crops. The grain is used largely as feed for livestock, although some is processed directly into food for humans.

The flowering and fruiting structure is a terminal panicle that is usually lax or spreading. In some of the rarer types, the branches of the central axis are reduced so that in appearance the panicle approaches the spikes or heads of other small grains. The panicles may be either approximately symmetrical or with a preponderance of branches and their terminal spikelets hanging to one side, producing what is called side oats. The panicle is made up of numerous branches and spikelets which in turn are composed of two papery glumes and usually two florets. The primary and secondary florets are held together by a short, thin rachilla. The individual floret has a lemma and palea that enclose three stamens, a pistil and two lodicules.

After fertilization the pistil develops into a one-seeded fruit called a caryopsis. The fruit, also called the groat, is closely clasped by the lemma and palea except in hull-less types where it is freed upon threshing. In *Avena nuda*, an uncommonly grown naked species, spikelets may have eight to ten florets, and two to eight may be fertile.

The lemma and palea, the covering or hulls containing the groat, are usually without hairs for the most part in cultivated oats (*Avena sativa*). In a large number of the wild forms, however, the lemma is covered with numerous hairs. The lemma also bears a weak awn in many cultivated varieties and sometimes a large and twisted awn as in the case of the wild types. The hull colour at maturity may vary considerably from yellow to white, black, brown or red. In some wild species of oats empty glumes remain attached to the panicle branches after the kernels have fallen to the ground. In cultivated species, however, most of the kernels remain attached until threshed. The basal articulation of the spikelet is useful in the classification of species. Sometimes the secondary kernel is tightly clasped by the lemma of the primary kernel; this is known as doubling or bosom kernels. Sometimes the first flower may be sterile and yet not doubled. The caryopsis or groat weighs about 20 mg. and the lemma and palea about 6 mg. in cultivated oats. The oat panicle usually is from 4 to 21 in. long and may have as few as 8 to 10 kernels or as many as 200, and averages about 45 kernels in number.

The leaves of the oat plant are thin, narrow and long. They are very prominent in the early phases of growth, but become less prominent upon maturity, at which time the culms are elongated and produce what is called the stalk or culm of the plant. There is no auricle at the base of the leaf blade, this being in contrast with the other small grains. The stems are usually hollow except at the nodes. Culms are from two to five feet tall and the number per plant depends largely upon the rate of sowing, the fertility of the soil and growth conditions. Roots are fibrous and numerous, and penetrate the soil to various depths.

Origin.—It was previously thought that cultivated oats were derived chiefly from two species, the common wild oat (*Avena fatua*) and the wild red oat (*A. sterilis*). Some cereal workers held that common white oats (*A. sativa*) were derived from *A. fatua* with a spreading panicle and that red oats (*A. byzantina*) came from *A. sterilis*. Later some workers believed that *A. sterilis* was the progenitor of both the red oats and white oats. Wild oats were first found growing in different regions of western Europe. Early writers mentioned the possibility that oats were found as a weed mixed with barley and therefore may have been distributed as a mixture in barley. From western Europe oats spread to other temperate parts of the world and have been in production under a wide range of conditions

Classification.—The genus *Avena* is composed of polyploid series, as is true of *Triticum*, the haploid chromosomes numbering 7, 14 and 21, or 14, 28 and 42 in the vegetative cells. There are several recognized species in the 7-chromosome group, most of

them being wild types. There are at least two species recognized as being in the 14-chromosome group. In the third group with 21 chromosomes are found the common white and yellow cultivated varieties, ordinary wild types, hull-less and *Avena byzantina,* the cultivated red oat. There are also wild forms found in this series.

The different species have been classified by numerous workers, most of whom do not agree in detail.

The common wild oat is a weed in many sections of the world although in some areas it is cut for hay or grazed. Because the seeds may lie dormant for long periods it is difficult to eradicate this type of oat. Kernels mature more rapidly at the top of the panicle and drop to the ground as they ripen, even though the culm may still be green. The panicle of the wild oat is usually longer and more lax than that of the ordinary cultivated sorts.

Fatuoids or false wild oats have been observed in nearly all cultivated varieties. Fatuoid kernels also drop to the ground as in the case of wild oats. However, false wild types do not constitute a weed hazard.

The various common oats are grown in cooler and more temperate regions of the world. Side and late-maturing common oats occur in northwestern Europe and northern sections of the United States and Canada. The smaller yellow-kernelled varieties occur in southwestern U.S.S.R. and in the corn belt of the United States. Red oats are grown principally in the warmer climates, including the southern sections of the United States and the Mediterranean regions of Europe and Africa. Australia also produces some of the common red oats. These are considerably more heat tolerant than are the common types. Hull-less (*A. nuda*) forms are found in the highlands of Tibet, northern India, Turkestan and western China.

Some of the more important older agricultural varieties of oats in North America are Kherson, Silvermine, Victory, Fulghum, Red Rustproof, Markton, Gopher, Columbia, Cornellian, Patterson, Banner, O.A.C. selections, the "Victoria-Richland" group and "Bond" varieties including Clinton, Bonda and Cherokee. Some of the newer varieties are Branch, Clintland, Craig, Floriland, Mustang and Sauk. Varieties from other sections of the world are as follows: Victory, Record, Golden Rain, Potato, Elder, La Industria, Binder, Golden Rain II, Gelbhafer, Sunrise, S.E.S. no. 52, Victoria, Red Algerian, Belar, Dun, Santa Fe and Landhafer.

Cultivation and Use.—A large part of the oats produced in the United States is sown in the spring. There are three groups of spring-sown oats: those that are of midseason to late in maturity; early white and yellow types; and the spring-sown red types that are grown principally in the Great Plains of the United States. There is also a large area of fall-sown oats in the southern section of the United States. Seeding is done in practically all months of the year in various areas of the world.

Oats are less exacting in their soil requirements than are other cereals with the exception of rye. They seem to be able to extract nutrients from the soil that would not be available for wheat and barley. In the presence of sufficient moisture, oats will do comparatively well on soils that are sandy and low in fertility and on soils high in acidity, but will do well under fertile conditions. Rye, however, as a rule will produce crops on soils that are too poor for satisfactory oat production. In the corn belt of the U.S. oats are grown widely in rotation with corn and forage crops. Oats are used as a nurse crop with grasses and legumes that are to be used later for forage purposes. Since oat culture is relatively simple, a good crop may be obtained by either disking or plowing in the fall or spring, followed by sowing seed with a grain drill or with a broadcast seeder. The rate of seeding is about ten pecks to the acre.

Production is usually greater when sown soon after frost has left the ground in the spring-sown area. Various kinds of machines may be used for harvesting, according to local conditions. One method is the use of a binder followed by shocking the bundles and then threshing by means of a separator. In some areas harvesting is done by more primitive means.

In the early 1950s about 93% of the U.S. crop was used for feed. It is fed to all classes of livestock as grain in pure form or in mixtures of feed. The straw is used for animal feed and is excellent for animal bedding. Oats are also used for pasturing in various sections of the world, and the crop is also cut for hay. Oats have long been a favourite source of breakfast food. Rolled oats or oatmeal is used mostly for porridge, although other kinds of breakfast food are manufactured from the grain of the oat plant. It is also used in cookies, breads and puddings.

The oat grain is known to be high in protein and fat content. It is also a very good source of vitamin B_1, and has an appreciable amount of vitamin E. The grain has as much riboflavin as other cereals, but much less niacin than wheat. It is practically devoid of vitamins C and D. Leaves of growing young plants are high in a large number of nutritional elements including the "grass juice factor," which is in commercial usage.

The oat crop enters industrial usage to a small extent. Other than breakfast foods one of the principal industrial products is the liquid aldehyde called furfural. This is made by the destructive distillation of the oat hulls in the presence of acid and steam under regulated conditions. Furfural is used in selective solvents for various purification purposes, in paint remover, lacquer solvents and in adiponitrile, which in turn is used in developing nylon. Limited medical products come from oats.

In most regions of the world, oat culture faces the hazards of rust, smut, *Septoria* and other diseases which may greatly reduce yield and quality. Plant breeders strive to attain resistance to these major diseases and to lodging for the enhancement of quality and yields. In certain areas drought resistance and the survival of fall-sown varieties are much-needed characteristics sought by the plant breeder. Inasmuch as oats are self-pollinated and breed true after pure lining, improvements are easily utilized in production increase. The development of new varieties by means of hybridization followed by purification and testing has commanded considerable attention from oat breeders the world over for many years.

One of the main problems in breeding is the selection of plant progenies in early generations that will resist disease and have high productive capacity. Specialized races of pathogenic fungi complicate the problem of breeding for disease resistance. In the decades between 1930 and 1950 much progress was made in oat breeding in the United States. During those years hybridization and selection were used to develop smut- and rust-resistant varieties. After 1950 plant breeders experimented with several types of irradiation and chemicals with the hope of inducing gene mutations for disease resistance.

Production.—For several years world production averaged about 4,300,000,000 bu. on about 130,000,000 ac. European and Asian production was a bit low immediately after World War II.

For the ten-year period 1942–51, the United States averaged 1,324,614,000 bu., averaging 33.5 bu. per acre. The years of highest production, about 1,500,000,000 bu., were 1945 and 1946, when the predominant varieties were the "Victoria" group, Vicland Tama, etc. Because of susceptibility of the fungus *Helminthosporium victoriae,* these varieties were replaced by the "Bond" group, Clinton, Bonda, etc., which later proved susceptible to leaf rust and race 7 of stem rust. Other principal producing nations, with approximate post-World War II annual averages, were: U.S.S.R., 720,000,000 bu.; Canada, 340,000,000; France, 225,000,000; Federal Republic of Germany, 145,000,000; United Kingdom, 200,000,000. (H. L. Ss.)

OAXACA or OAXACA DE JUÁREZ, capital of the state of Oaxaca de Juárez, Mex. Pop. (1950 est.) 45,000. At an altitude of 5,070 ft., Oaxaca stands in the warm, semitropical temperate Valley of Oaxaca, flanked by lesser fertile valleys and ranges of the Sierra Madre del Sur. The Pan-American highway, continuing south from Mexico City, passes through Oaxaca en route to Tehuantepec and Guatemala. In 1947 the narrow-gauge rail connection to Puebla, 211 mi. N., was broadened to standardize the track. By mid-century a projected highway of 180 mi. to the Pacific port Puerto Angel had been paved to Miahuatlán.

A beautiful colonial city, Oaxaca is notable for its green onyx buildings, especially the 16th-century cathedral, its important Indian market and its handicraft industries. It is built on the site of an Aztec garrison post founded in 1486. (HD. C.)

OAXACA DE JUÁREZ, a southern state of Mexico that includes the greater part of the Isthmus of Tehuantepec on its Pacific side. Pop. (1950) 1,444,929, the majority of whom are Indians divided into more than 15 major tribes. Area, 36,365 sq.mi. The capital, Oaxaca de Juárez (*q.v.*), is near the centre of the state on a high plateau girt by mountains. Northern maritime ranges of Mexico join to form the Sierra Madre del Sur, which runs southeasterly through central Oaxaca with many peaks more than 10,000 ft. high and culminating in Zempoaltepec (11,142 ft.), from which minor spurs extend; the Sierra dies on the Isthmus of Tehuantepec, which is low, hot and arid, as are other Pacific coastal lowlands. The Atlantic lowlands near Veracruz are hot and humid, but most of the state enjoys mild, healthful conditions in its several broad valleys and fertile uplands. The Pan-American highway from Mexico City traverses the state

southeasterly through the Valley of Oaxaca and across the isthmus, while transisthmian rail lines from Puerto Mexico to Salina Cruz (*q.v.*) and trunk lines from Puebla and Veracruz form an incomplete rail net within the state.

Oaxaca is an agricultural and mining area, with a broad range of crops and products, chief among which are maize, wheat, coffee, sugar, tobacco, fibres and tropical fruits. It manufactures items for local consumption: cigarettes, soap and famous Indian blankets or serapes from wool. Its mountains are veined with minerals, including gold, silver, uranium, diamonds, onyx and many minor substances. In colonial times Oaxaca was a fabulous producer of silk and of cochineal for dyestuffs.

In pre-Columbian times the state was inhabited by many Indian groups, chief of whom were the kingdoms of the Zapotecos and Mixtecos, whose remains are found at Mitla and Monte Alban (*see* CENTRAL AMERICA: *Archaeology*) and whose descendants form the majority of the population. Benito Juárez, after whom the state is named, and Porfirio Díaz were born in Oaxaca.

(HD. C.)

OB or **OBI,** river of Asiatic Russia, known to the Ostiaks as the As, Yag, Kolta and Yema; to the Samoyedes as the Kolta or Kuay; and to the Tatars as the Omar or Umar. Its length is roughly 3,200 mi.; the area of its basin is considerably more than 1,000,000 sq.mi. and the navigable waters in its basin total more than 17,000 mi. Its source is in the Altai mountains and its course is through hilly country to the Kirghiz steppe and thence it flows to its delta in the gulf of Ob, an inlet of the Arctic ocean 600 mi. in length. In its middle course, south of its junction with the Irtish, and extending between the two streams, are the Vasuigan swamps, named from the Vasuiga, a left bank tributary of the Ob. They extend for 100,000 sq.mi. and in summer are impassable marshes, with dense thickets of cedars, larches and pines. In spring they are flooded and are then known as the Vasuigan sea. In winter they become ice-bound and may be crossed. When drained the land proves fertile. North of the swamps the river flows through coniferous forest to Berezov, and passes Obdorsk, where there is a Veterinary Institute for the help of the reindeer breeders and to which small sea-going vessels can penetrate.

After receiving its largest tributary, the Irtish, the Ob divides into more than one arm and is of little use for navigation except for barges bringing fish from the delta in the autumn. Above the junction of the Irtish, steamers and barges ply upon the Ob and its tributaries the Irtish, the Tobol, the Tavda and the Tura in summer. In 1915 there were 350 steamers and several hundred barges chiefly carrying corn, flour, salt and timber, in addition to passengers. The east-west river traffic is giving place to railway communication, but the north-south route is still important. The river is frozen from November to May or June; floods, ice and floating timber impede navigation for some time after the thaw.

The fact that in its southern parts the Ob approaches so close to the Yenisei that short and easy portages link them, made the penetration of Siberia by the Cossacks an easy task. The Chulim, a tributary of the Ob, in its upper course is at one point only 6 mi. from the Yenisei, but a canal link is impossible owing to the great difference in level, while the Ket river, another right bank tributary of the Ob has canal communication with the Kas, a tributary of the Yenisei.

The Irtish, which is quite as important as the Ob, rises as the Black Irtish, south of the Mongolian border, and flows through the Dzungarian gate into Russia, where it expands into Lake Zaisan, and then cuts its way across a spur of the Altai into the plains. There are lakes, many of which are salt and are rapidly drying; flourishing villages stand on the site of what in the early part of last century was Lake Chany.

OBADIAH, the fourth of the "minor prophets," the otherwise unknown author of the shortest book in the Old Testament, whose 21 verses, even, show evidence of the expansion or addition of which a manuscript, as distinct from a printed book, so easily admits. Whilst the first fourteen verses address Edom in the second person singular, with apparent reference to recent disasters that have befallen that people, the last six address Israel in the second person plural, promising judgment on the nations, including Edom, and proclaiming the eschatological "Day of Yahweh," when the lost territories shall be recovered. (The "join" is made in verse 15, of which *a* belongs to the latter, and *b* to the former, prophecy.) The Edomites (identified with "Esau," verse 6; *cf.* Gen. xxxvi. 1) occupied the mountainous country south of the Dead Sea, on both sides of the Arabah; hence the reference to their rock-dwellings (verse 3). The aid which they gave to the Babylonians against Jerusalem in 586 (Ps. cxxxvii. 7, etc.) was never forgiven, and its remembrance inspires the present prophecy (verses 11ff.). The actual disaster that befell the Edomites was probably some invasion by the neighbouring nomads, *e.g.*, the Nabatean Arabs (verse 7). The opening paragraph of Malachi may refer to the same event; if so, we may suppose the prophecy of Obadiah in its earlier part to belong to the first half of the fifth century B.C. The dominant thought of it is that at last Edom has received its deserts at the hand of Yahweh. We do not know at what date this earlier portion was continued and incorporated into the more general prophecy concerning the future vindication of Judah, with which the book now closes. The original prophecy has elsewhere been reproduced, as well as expanded. Its first five verses occur in almost the same form in Jer. xlix. 14–16 & 9 (*cf.* also Joel ii. 32), a passage probably later than Obadiah. *See* EDOM.

OBAN, small burgh and seaport, Argyllshire, Scotland, 113 mi. N.W. of Glasgow by L.M.S., and about the same distance by water. Pop. (est. 1938) 5,794. Its bay is screened by the island of Kerrera and sheltered by hills to the north and east. The Roman Catholic pro-cathedral was erected by the 3rd marquis of Bute. Oban, a government fishing station in 1786, is now the centre of tourist traffic for western Argyllshire and the islands.

At the north end of the bay stands the ruin of Dunolly Castle, the old stronghold of the Macdougalls of Lorne, whose modern mansion adjoins it. In the grounds is a huge conglomerate rock called the Dog Stone (*Clach-a-choin*), from the legend that Fingal used to fasten his favourite dog Bran to it. About 3 m. N.E. are the ruins of Dunstaffnage Castle. It was here that the "Stone of Destiny," now contained in the base of the coronation chair at Westminster Abbey, was kept before its removal to Scone.

OBBLIGATO or **OBLIGATO,** in the modern sense, a musical term for an instrumental accompaniment to a musical composition which, while in one way independent, is included by the composer on purpose and in a prescribed form, instead of being left to the discretion (*ad libitum*) of a performer.

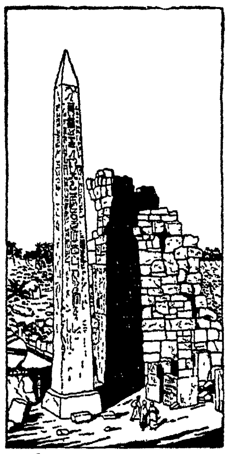
OBEDIENT-PLANT (*Physostegia virginiana*), a North American herb of the mint family (*Labiatae*), called also false dragon-head and lion's-heart, native to moist soil from Quebec to Ontario and Minnesota, and south to Florida and Texas. It is an erect, usually unbranched perennial, 1 to 4 ft. high, bearing oblong or lance-shaped, sharply-toothed, pointed leaves and dense terminal clusters (spikes) of pale-purple, rose-coloured or sometimes white flowers, about 1 in. long. The flower displays the peculiar characteristic of remaining temporarily at whatever angle it may be placed with reference to the stem.

OBELISK, a form of monumental pillar; and also the term for a bibliographical reference-mark in the form of a dagger. The typical Egyptian obelisk is an upright monolith of nearly square section, generally ten diameters in height, the sides slightly convex, tapering upwards very gradually and evenly, and terminated by a pyramidion whose faces are inclined at an angle of 60°. Obelisks were usually raised on pedestals of cubical form resting on one or two steps, and were set up in pairs in front of the entrance of temples. Small obelisks have been found in tombs of the Old Kingdom. The earliest temple obelisk still in position is that of

Senwosri I. of the XIIth Dynasty at Heliopolis (68 ft. high). A pair of Rameses II. (77 and 75 ft. high respectively) stood at Luxor until one was taken to Paris in 1831. Single ones of Tethmosis I. and Hatshepsut still stand at Karnak and remains of others exist there and elsewhere in Egypt. Colossal obelisks were erected by only a few kings, Senwosri I. in the Middle Kingdom and Tethmosis I., Hatshepsut, Tethmosis III. and Rameses II. of the Empire. Smaller obelisks were made in the Saïte period. The Romans admired them, and the emperors carried off some from their original sites and made others in imitation (*e.g.*, that for Antinous at Benevento); 12 are at Rome, one in Constantinople; two, originally set up by Tethmosis III. at Heliopolis, were taken by Augustus to adorn the Caesareum at Alexandria: one of these, "Cleopatra's Needle," was removed in 1877 to London, the other in 1879 to New York. The pyramidions were sheathed in bright metal, reflecting the sun's rays as if they were thrones of the sunlight. They were dedicated to solar deities, and were especially numerous at Heliopolis, where there was probably one of immemorial antiquity sacred to the sun. The principal part of the sun-temple at Abusir built by Neuserrē of the Vth Dynasty appears to have been in the shape of a stumpy obelisk on a vast scale; only the base now remains, but hieroglyphic pictures indicate this form. The hieroglyph of some other early sun-temples shows a disc on the pyramidion . The material employed for the great obelisks was a pink granite from Syene, and in these quarries there still remains, partially detached, an example 70 to 80 ft. long. The largest obelisk known is that in the piazza of St. John Lateran at Rome, set up by Tethmosis III. at Heliopolis in the 15th century B.C. and brought from Egypt by Constantine the Great and erected in the Circus Maximus, being ultimately re-erected in 1552 by Pope Sixtus V. It was 105 ft. 9 in. high, including the pyramidion, and its sides measured 9 ft. 10 in. and 9 ft. 8 in. respectively. On the base of the obelisk of Hatshepsut at Karnak, 97 ft. 6 in. high, there is an inscription stating that it and its fellow were made within the short space of seven months.

There was another form of obelisk, also tapering, but more squat than the usual type, with two of the sides narrow and terminating in a rounded top. One such of Senwosri I., covered with sculpture and inscriptions, lies at Ebgīg in the Fayum.

In Abyssinia, at Axum and elsewhere, there is a marvellous series of obelisk-like monuments, probably sepulchral. They range from rude menhirs a few feet high to elaborately sculptured monoliths of 100 feet. The loftiest of those still standing at Axum is about 60 ft. high, 8 ft. 7 in. wide, and about 18 in. thick, and is terminated by a rounded apex united by a necking to the shaft. The back of the obelisk is plain, but the front and sides are subdivided into storeys by a series of bands and plates, each storey having panels sunk into it which seem to represent windows with mullions and transom. These architectural decorations are derived from a style of building as found by a German expedition extant in an ancient church; courses of stone here alternate in the walls (both inside and out) with beams of wood held by circular clamps. In front of the best-preserved obelisk is a raised altar with holes sunk in it apparently to receive the blood of the sacrifice to the ancestors. Most of these must date before the adoption of Christianity as the State religion in the 6th century.



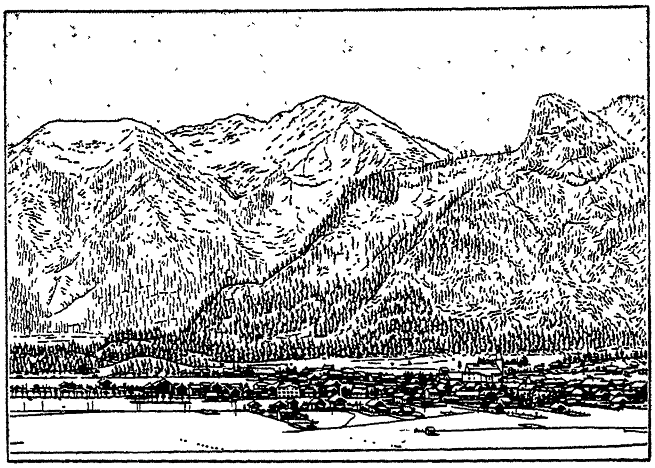
OBELISK (KARNAK)

See G. Maspero, *L'Archéologie égyptienne* (new ed., 1907); H. H. Gorringe, *Egyptian Obelisks* (New York, 1882; London, 1885, etc.); F. W. von Bissing and L. Borchardt, *Das Re-Heiligtum des Königs Ne-woser-Re* (1905); on the ancient method of raising obelisks, L. Borchardt, "Zur Baugeschichte des Amonstempel von Karnak," in Sethe's *Untersuchungen zur Geschichte und Altertumskunde Aegyptens*, vol. xv. For the Abyssinian obelisks *see* especially E. Littmann and D. Krencker, *Vorbericht der deutschen Aksum Expedition* (1906). (F. Ll. G.)

OBERAMMERGAU, a village of Bavaria, Germany, situated among the foot-hills of Kofel mountains, a range of the Alps, in the Ammer valley, 64 m. S.S.W. of Munich. Pop. about 1,700. The outside walls of many of the houses are decorated with fresco paintings, reproductions of famous biblical masterpieces. The villagers make toys and pottery, and carve wooden crucifixes, rosaries and images of saints. These carvings are shipped to all parts of the world and are found in many churches.

THE OBERAMMERGAU PASSION PLAY

The village is famous for its performance of a Passion play every ten years. This is probably the most important survival of the miracle plays so popular from the 13th to the 16th century. Contrary to popular belief, this production is not a portrayal of the life of Christ, but only of the events of his last few days on earth, known as Passion week.



A VIEW OF THE VILLAGE OF OBERAMMERGAU, SITUATED IN THE MOUNTAINS OF BAVARIA

In 1633 the village was stricken with the scourge of the Black Death. As an expression of gratitude for the cessation of the scourge the inhabitants vowed to enact the Passion and death of Christ every ten years. The first performance was given in 1634 and repeated every ten years until 1674, after which the dates were changed so as to fall on decimal years. This now has been faithfully kept with the exception of 1870, when the Franco-Prussian War interfered. The earliest extant text of the play was written in 1662, probably by the monks of Ettal, a monastery situated a few miles from Oberammergau. The text is slightly revised every ten years. The music was composed by Rochus Dedler, a schoolmaster of the parish, in 1814. The initial performance of the play is given the first Sunday in May, and is repeated every Sunday, with two or three extra performances each week. On account of the unsettled conditions resulting from the World War the 1920 production was postponed until 1922, during which year it was played 61 times. It starts at eight o'clock in the morning and continues for eight hours, with a short intermission at noon. The characters are chosen by a committee made up of the village priest, burgomaster, village council and members selected by popular vote. No one may participate in the spectacle unless he is a native of the village and is of unimpeachable moral character and dramatically qualified to enact the rôle for which he is chosen. Over 700 characters participate in the play. This includes the orchestra of 50 members and the chorus of 46. It is estimated that more than 300,000 witness the production each season. The proceeds are divided into four equal parts: one for the preparation of the play, one for the furnishing of homes for the visitors, one for the church and one for the players.

The play is enacted on a large open-air platform, the audience occupying an auditorium with a capacity of about 6,000, viewing the play through an immense oval opening in front of the auditorium. The play consists of 18 acts and a number of tableaux. Each act is prefaced by an orchestral selection and a choral anthem giving the motif of the act. This, in turn, is followed by

a tableau based on the Old Testament prefiguring the theme of the act. For instance, the scene depicting the Crucifixion is preceded by a tableau representing the offering of Isaac as a sacrifice by Abraham. The chief characters are the Christus, the Twelve Disciples, Mary the mother of Jesus, Mary Magdalene and Martha. Anton Lang (1875–1938) held the distinction of portraying the part of the Christus for three decades, 1900, 1910 and 1922. The participants regard their rôles with religious devotion and enact their parts with the deepest reverence. In the years between the representations of the play, performances are given of many classics for the purpose of training the prospective players for the Passion play, in enunciation, stage bearing and all other requirements of dramatizing. No wigs or facial make-up are permitted. The costumes, however, are of the biblical period and are of the very best material. The participants train their hair and beards and study to assume the general appearance of the characters for which they are candidates.

OBERHAUSEN, a town in the Prussian Rhine province, Germany, 5 mi. east of the Rhine, 20 mi. N.E. of Düsseldorf, on the main railway line to Hanover and Berlin, and at the centre of an important network of lines radiating hence into the Westphalian coal and iron fields. Pop. (1939) 191,305. The first houses of Oberhausen were built in 1845, and it received its municipal character in 1874. The town has large iron-works, coal-mines, rolling-mills, zinc smelting-works, dye-works, railway workshops and manufactures of wire-rope, glass, chemicals, sugar, porcelain and soap. It was bombed in World War II.

OBERLIN, a city of Lorain county, Ohio, U.S., 34 mi. W.S.W. of Cleveland, on federal highway 20 (by-pass) and served by the New York Central lines and bus. Population in 1950 was 6,457. It is a pleasant residential city, the seat of Oberlin college. In 1926 it adopted a manager form of government. Oberlin college was founded in 1833 by the Rev. John J. Shipherd (1802–44) and Philo P. Stewart (1798–1868), and was named after John Frederick Oberlin (d. 1826), the Alsatian pastor and philanthropist. Its educational plant at mid-20th century was valued at about $9,800,000; its endowment funds aggregated $24,000,000; the library had about 500,000 bound volumes; and the student body numbered more than 2,000. Oberlin college includes the college of arts and sciences, the graduate school of theology and the conservatory of music.

The "Oberlin theology" (not now identified with the college) centred in the teachings of Pres. Charles Finney, a powerful preacher and teacher, who carried on remarkable revival services in eastern cities of America and in England and Scotland. The modern theological position of the college was reflected in the writings of Pres. Henry C. King (1858–1934) and of Dean Edward I. Bosworth of the theological seminary (1861–1927). Oberlin was the first American college to adopt coeducation, and in Aug. 1841 three women were regularly graduated from the classical course—the first women in America to receive the degree of bachelor of arts on conditions like those prevailing in the best men's colleges of the time. Oberlin was also a pioneer (1835) in refusing to debar students on account of race. A substantial proportion of the students earn part of their expenses.

Oberlin was a "station" on the underground railroad. The attic of President Finney's home frequently sheltered slaves who were escaping to Canada. In 1858 a runaway slave, John Price, was captured in Oberlin by a U.S. marshal, and was rescued at Wellington (9 mi. S.) by a band of Oberlin professors and others, in consequence of which 30 professors were arrested and imprisoned. This was a famous fugitive slave case. The village was founded as a home for the college, and was incorporated in 1846.

OBERON, king of the elves. In the legendary history of the Merovingian dynasty he is a magician, brother of Merowech (Mérovée). In the *Nibelungenlied* he guarded the treasure of the Nibelungen. In the German mediaeval poem of *Ortnit,* the hero is aided in his wooing by his father Alberich, the king of the dwarfs. As Oberon, king of the fairies, he fills a similar rôle in *Huon of Bordeaux* (*q.v.*). Shakespeare used the fairy element in *A Midsummer Night's Dream,* and Wieland in his epic *Oberon* (1780). Ben Jonson wrote a masque of *Oberon, or the Fairy Prince* (*Works,* 1616). Weber's opera, *Oberon,* to the words of J. R. Planché, was first produced at Covent Garden in 1826.

See also C. Voretzsch, *Epische Studien. Die Kompositionen des Huon von Bordeaux* (Halle, 1900).

OBITER DICTUM, that which is said by the way; specifically, in law, an opinion expressed by a judge incidentally in the course of a case, on a point of law not material to the issue or to the grounds of the decision; such *obiter dicta* have no binding authority.

OBJECT and **SUBJECT,** in philosophy, the terms used to denote respectively the external world and consciousness. The term "object" is used generally in philosophy for that in which an activity of the mind ends, or towards which it is directed. With these may be compared the ordinary uses of the term for "thing" simply, or for that after which one strives, or at which one aims. "Subject," is originally the material or content of a discussion or thought, but in philosophy is used for the thought or the thinking person. The relation between the thinking subject and the object thought is analogous to the grammatical antithesis of the same terms: the "subject" of a verb is the person or thing from which the action proceeds, while the "object," direct or indirect, is the person or thing affected. The true relation between mind or thought (subject) and matter or extension (object) is the chief problem of philosophy, and may be investigated from various standpoints (*see* PSYCHOLOGY and METAPHYSICS).

OBJECTIVISM, in philosophy, a term used, in contradistinction to SUBJECTIVISM, for any theory of knowledge which to a greater or less extent attributes reality (as the source and necessary pre-requisite of knowledge) to the external world. The distinction is based upon the philosophical antithesis of the terms Object and Subject, and their respective adjectival forms "objective" and "subjective." In common use these terms are opposed as synonymous respectively with "real" and "imaginary," "practical" and "theoretical," "physical" and "psychic." A man "sees" an apparition; was there any physical manifestation, or was it merely a creation of his mind? If the latter the phenomenon is described as purely subjective. Subjectivism in its extreme form denies that mind can know more than its own states. Objects, *i.e.,* things-in-themselves, may or may not exist: the mind knows only its own sensations, perceptions, ideal constructions and so forth. In a modified form "subjectivism" is the philosophic theory which attaches special importance to the part played by the mind in the accumulation of experience. *See* PSYCHOLOGY and related articles.

OBLATE, an ecclesiastical term for persons not professed monks, friars or nuns, who have devoted themselves or have been devoted as children by their parents to a religious life. "Oblate" is more familiar in the Roman Church as the name of a religious congregation of secular priests, the Oblate Fathers of St. Charles. This congregation was founded in 1578 under the name of Oblates of the Blessed Virgin and St. Ambrose by St. Charles Borromeo, archbishop of Milan (*see* BORROMEO, CARLO). There is a similar congregation of secular priests, the Oblates of Mary the Immaculate, founded at Marseilles in 1815. *See* the *Catholic Encyclopaedia, s.v.* "Oblate."

OBLATION, an offering, a term, particularly in ecclesiastical usage, for a solemn offering or presentation to God. It is thus applied to certain parts of the Eucharistic service in the Roman Church. There are "two oblations," the "lesser oblation," in which the bread and wine yet unconsecrated are presented after the offertory, and the "greater oblation;" the "oblation" proper, forming the latter part of the prayer of consecration, when the "Body and Blood" are ceremonially presented. *See* the *Catholic Encyclopaedia, s.v.* "Oblation."

OBLIGATION, in law, a term derived from the Roman law, in which *obligatio* signified a tie of law (*vinculum iuris*), whereby one person is bound to perform or forbear some act for another. The *obligatio* of Roman law arose either from voluntary acts or from circumstances to which legal consequences were annexed. In the former case it was said to arise from contract, in the latter

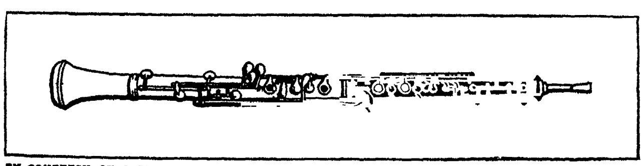
from tort, or from acts or omissions to which the law practically attached the same results as it did to contract or tort. *Obligatio* was used to denote either end of the legal chain that bound the parties, the right of the party who could compel fulfilment of the *obligatio*, the *creditor*, or the duty of the party who could be compelled to fulfilment, the *debitor*. In English law obligation has only the latter sense. Creditor and debtor have also lost their Roman law signification; they have been narrowed to mean the parties where the obligation is the payment of a sum of money. But in legal systems, chiefly founded on Roman law, the original meanings remain. In English law obligation is used in at least four senses—(1) any duty imposed by law; (2) the special duty created by a *vinculum juris*; (3) not the duty, but the evidence of the duty—that is to say, an instrument under seal, otherwise called a bond; (4) the operative part of a bond. The third and fourth uses of the word are chiefly confined to the older writers. The party bound is still called the obligor, the party in whose favour the bond is made the obligee. The word "bond" is, of course, a mere translation of *obligatio*. Obligations may be either perfect or imperfect. A perfect obligation is one which is directly enforceable by legal proceedings; an imperfect or moral obligation (the *naturalis obligatio* of Roman Law) is one in which the *vinculum juris* is in some respects incomplete, so that it cannot be directly enforced, though it is not entirely destitute of legal effect.

American law is in general agreement with English. The term obligation is important in the U.S.A. from its use in art. i. s. 10 of the constitution, "No state . . . shall pass any . . . law . . . impairing the obligation of contracts." This does not affect the power of Congress to pass such a law.

OBOE or **HAUTBOY.** The treble member of the class of wood-wind instruments having a conical bore and a double reed mouthpiece, the oboe consists of a conical wooden tube, composed of three joints, upper, middle and bell, and of a short metal tube to which are bound by many turns of waxed silk the two thin pieces of cane that form the mouthpiece. These pieces of cane are so bevelled and thinned at the end which is taken into the mouth that the gentlest stream of compressed air suffices to set them vibrating and thereby to set up the rhythmical series of pulses which generate the sound waves in the stationary column of air within the main tube of the instrument.

The compass of the oboe is from B flat below the treble stave to F in alt, or even a note or two higher, with all chromatic semitones. Its quality of tone is thin, penetrating and even somewhat nasal. It is possible to play on it diatonic and chromatic scale and arpeggio passages, legato and staccato; leaps; cantabile passages; sustained notes, crescendo and diminuendo, grace notes and shakes (with reservations).

The first appearance of the instrument in a musical work occurs in Sebastian Virdung's *Musica getutscht und aussgezogen* (1511). It there bears the name of *Schalmey*, and is already associated with an instrument of similar construction called *Bombardt*. There exists, however, much earlier evidence, in the illuminated mss. and in the romances of the Middle Ages, of the great popularity of the instrument in all parts of Europe. The oboe was known during the early Middle Ages as *Calamus, Chalumeau* (France), *Schalmei* (Germany) and *Shawm* (England), while after the Renaissance we find instruments of this type ranged in complete families from the soprano to the bass and known respectively as the little Schalmey; the discant Schalmey; the alto Pommer; the tenor Pommer; the bass Pommer; and the great double quint Pommer.



BY COURTESY OF CARL FISCHER, INC., NEW YORK

THE OBOE IN ITS MODERN FORM

The 17th century brought no great changes in the construction of the four smaller instruments of the family. Extensively used in France, they were there called "haulx bois" or "hault-bois," to distinguish them from the two larger instruments which were designated by the words "gros bois." Haultbois became hautbois in French, and oboe in English, German and Italian; and this word is now used to distinguish the smallest instrument of the family still in use.

The reform in the construction of the flute due to Theobald Boehm of Munich about 1840, a reform which principally consisted in the rational division of the tube by the position of the lateral holes, prompted Triebert to try to adapt the innovation to the oboes and bassoons; but he failed, because the application of the system denaturalized the timbre of the instruments, which it was necessary, before all things, to preserve. Further improvements, however, made upon the same lines by Barret and later by Rudall Carte, have transformed the oboe into the most delicate and perfect of reed instruments, as which it constitutes one of the most valuable and indispensable members of the modern orchestra.

OBOK, a seaport on the north shore of the Gulf of Tajura, N.E. Africa, acquired by France in 1862. It gave its name to the colony of Obok (now French Somali coast protectorate). (*See* SOMALILAND: *French.*) The port is separated from the open sea by coral reefs, but is only partially sheltered from the winds. The French in 1896 transferred to Jibuti, on the opposite shore of the Gulf, the seat of government of the colony. Obok is connected with Aden and Jibuti by submarine cables. It is only a native village with a population of about 300.

OBRECHT, JACOB (also HOLBRECHT) (*c.* 1430–*c.* 1500), Dutch composer, was born probably at Utrecht about 1430. About 1474 Erasmus was under him as a choir boy at Utrecht, where he was chapel master, and in the same year Obrecht seems to have held an appointment at Ferrara. He was afterwards director of the Cambrai school of singing, and at some time lived in Florence, where his name is associated with Josquin, Isaac and Africola, and the musicians who clustered round Lorenzo's court. The principal records of his later years are found in Antwerp Cathedral, where he was chapel master from 1491 until his death. That he possessed immense contrapuntal skill and was considered one of the greatest masters of the age there is evidence in the praise of his contemporaries and successors, the honours bestowed upon him, and the visits received by him at Antwerp. The finest of his eight masses, *Fortuna Desperata*, was published in Amsterdam (1870) and appears in 1880 in the *Maatschappij tot Bevordering der Toonkunst* (*No. ix.*). He also wrote chansons and motets. The finest of the motets is *Salve crux arbor vitae*. Great interest attaches to his *Passion*, in which the chorus impersonates all the characters in the story and the narrative is given to the tenor in recitative.

A definitive edition of his works has been published by Johannes Wolf (*Werke van Jacob Obrecht*, Amsterdam and Leipzig).

OBREGÓN, ALVARO (1880–1928), Mexican soldier and president, was born in the district of Alamos, Sonora, on Feb. 17, 1880. During his early life as a planter he became an advocate of land reforms to better the condition of the peons and Indians, and in 1912 he entered the services of Madero, a man of similar ideals. With Indian troops which he recruited, Obregon aided in suppressing the revolt of Orozco against Madero, and later he again took the field against Felix Diaz whose successful revolt led to the downfall of Madero and the establishment of Huerta as provisional president. Obregon then joined the counter-revolution of Carranza who had remained true to Madero. After a string of victories culminating in the successful storming of Sinaloa and Culiacan and the capture of Guadalajara, the way to Mexico City was opened, and on Aug. 15, 1914, Obregon led the Carranza troops into the capital. Huerta fled.

In the struggle which arose between Carranza and Zapata and Villa, Obregon remained loyal to Carranza. He defeated Zapata finally at Pueblo in Jan. 1915. In April he conducted a campaign against Villa for the control of central Mexico and by winning the battles of Celaya and Leon forced Villa back to his mountain fastnesses. As leader of the radical wing of Carranza's followers and chief of the army, Obregon possessed power enough to force into the new Constitution of 1917, against Carranza's wishes, the

famous article 27 which provided for the restoration of communal lands to the Indian villages, limited the size of individual land holdings, deprived religious organizations of the right to hold lands and reserved to the government the ownership of all mineral and petroleum resources. The new constitution also provided that no president should succeed himself, but in 1920 Carranza took steps to have himself retained in power, one of these steps being an order for the arrest of Obregon. Obregon escaped to Sonora where a revolt against Carranza was already in progress and put himself at the head of the troops. In a short time he was master of the situation and on Dec. 1, 1920, was elected president. He immediately adopted a friendly tone toward the United States and other foreign countries, and in 1923 the United States recognized his government. His administration was made notable by many labour and agrarian reforms and by a sincere effort to carry the provisions of the 1917 constitution into force. In 1924 he supported Calles, his minister of the interior, for president. His opponents under Huerta charged fraud in the election and started a revolution. Obregon once more took the field, defeated the rebels and drove Huerta into exile. Obregon was again elected president on July 1, 1928, but on July 17 before taking office he was assassinated.

O'BRIEN, WILLIAM (1852–1928), Irish patriot, was born at Mallow, Co. Cork, on Oct. 2, 1852, son of James O'Brien, a solicitor's clerk. He was educated at the Cloyne diocesan college and at Queen's college, Cork, and began journalism in 1869. In 1881 he became editor of *United Ireland*, which he conducted with such vigour (Aug.–Oct.) that it was suppressed for the time being, and O'Brien was shut up in Kilmainham jail with Charles Parnell and others. There he drew up the famous "No Rent" manifesto, which led to the Land league's being outlawed.

Released in 1882, O'Brien resumed his campaign in *United Ireland*. He was elected M.P. for Mallow in 1883. In 1886, O'Brien started the slogan of "no reduction, no rent." Parnell was much out of Ireland and eventually disavowed the "plan," but O'Brien had stirred up a fierce agitation, met by the British government with the Coercion act of 1887, under which O'Brien was sent to Tullamore jail. On his release he appeared in the house of commons to renew his obstructive tactics there.

After the O'Shea divorce case in which Parnell was involved he tried to mediate between the Parnellites and the anti-Parnellites, siding with the majority who rejected Parnell's claim to retain leadership. In 1900, after years of bitter strife, both sections were reunited under the Parnellite John Redmond, largely as a result of O'Brien's formation of the United Irish league. Having given active support to the Land conference, which secured agreement between the landlords and tenants' representatives and resulted in the Wyndham Land act of 1903, O'Brien became convinced that nationalists and unionists could unite for common purposes. He founded the All for Ireland league, which obtained a large following in County Cork, in opposition to Redmond's control of the United Irish league. But O'Brien's personal following did not survive the rise of the Sinn Fein agitation, and after World War I (Irish participation in which he had supported) he withdrew from public life. He died on Feb. 25, 1928.

O'BRIEN, WILLIAM SMITH (1803–1864), leader of Young Ireland, was born in Co. Clare on Oct. 17, 1803, and educated at Harrow and at Cambridge. He used his second name of Smith on inheriting his maternal grandfather's estates in Limerick. He entered parliament in 1828 as member for Ennis and from 1835 to 1848 represented the county of Limerick. Although he actively supported Catholic emancipation he opposed Daniel O'Connell's election for County Clare in 1828 and continued to oppose repeal of the legislative union until O'Connell's imprisonment at the end of 1843. O'Brien then joined the Repeal association and was at once appointed deputy leader while O'Connell was in prison. He became closely associated with Thomas Davis and Gavan Duffy and the brilliant group who later became the Young Ireland party; and in 1846 he led them in withdrawing from the Repeal association, when O'Connell demanded repudiation of any conceivable resort to arms. Early in 1847 they formed the Irish confederation, to press for a more active policy during the years of famine. In May 1848, after a mission to Paris to congratulate the new French republic, O'Brien was tried for sedition, but acquitted. He exercised a restraining influence while the young men urged preparations for an armed rising, but the government issued warrants to arrest all the most active leaders. O'Brien then assembled all the leaders to make a last stand in County Tipperary and appealed for a general rising. It collapsed in a short collision with the police and military at Ballingarry. O'Brien was arrested at Thurles, tried for high treason and sentenced to be hanged, drawn and quartered. The sentence was, however, commuted to exile to Tasmania for life. O'Brien obtained a full pardon in May 1856 and returned to Ireland. He died at Bangor, North Wales, on June 18, 1864.

OBSCENITY. By English common law it is an indictable misdemeanour to give an obscene exhibition or to publish any obscene matter, whether it be in writing or by pictures, effigy or otherwise. But the test of criminality as accepted in England is whether the exhibition or matter complained of tends to deprave and corrupt those whose minds are open to immoral influences and who are likely to visit the exhibition, or to see the matter published. If the exhibition or publication is calculated to have this effect, the motive of the publisher or exhibitor is immaterial. Even in the case of judicial proceedings, newspapers are not privileged to publish evidence which falls within the definition.

Besides the remedy by indictment there are statutory provisions for punishing as vagabonds persons who expose to public view in public streets or adjacent premises obscene prints, pictures or other indecent exhibitions. These are supplemented by the Indecent Advertisements act of 1889. By the Obscene Publications act of 1857 powers are given for searching premises on which obscene books, etc., are kept for sale, distribution, etc., and for ordering their destruction, and the post-office authorities have power to seize postal packets containing such matter and to prosecute the sender under the Post-Office act.

The use of obscene or indecent language in public places is punishable as a misdemeanour at common law, but it is usually dealt with summarily, under the Metropolitan Police act of 1839, or the Town Police Clauses act of 1847, or under local by-laws.

In the United States, the different states provide punishment for obscene libel, the exhibition of obscene pictures and the display or use of obscene language in public. The federal government penalizes sending of obscene matter through the mails.

Under the tariff act of 1930 (U.S. Code § 1305) the U.S. may ban the import of "any obscene book." "Obscene" is legally defined in the courts as "tending to stir the sex impulses or to lead to sexually impure thoughts." In a decision of the U.S. district court (1933) by Judge John M. Woolsey, the ban was lifted on James Joyce's modern classic *Ulysses*. Legal precedent was established in the opinion, which describes an investigation of a work of art on literary as well as juridical grounds, from the point of view of both intent and results.

Indecent acts committed with intent to insult females are punishable under the Vagrancy act of 1824 as amended by sec. 42 of the Criminal Justice act of 1925, and if committed otherwise under the acts of 1839 and 1847. (W. DE B. H.; X.)

OBSERVATORY (ASTRONOMICAL). The erection of special buildings for astronomical research is a practice of long standing. It is said by Diodorus that the great temple of Belus at Babylon was built for astronomical purposes, and, since there is indication in the Chinese records that the gnomon was used for measuring the height of the sun in the reign of the emperor Yao (2300 B.C.) it may be said that the beginning of practical astronomy was contemporaneous in eastern and western Asia. There is no evidence of the existence of an observatory of Greek or Alexandrine origin until the time of Ptolemy Soter, who, about 300 B.C., built one at Alexandria. The earliest records from an observatory known to be extant are those of Hipparchus (*c.* 140 B.C.) who has left a catalogue of stars from observations made at the island of Rhodes, repeating those made earlier at Alexandria.

AMERICAN OBSERVATORIES

1. The Lick observatory on Mt. Hamilton, Calif., completed in 1887–88. The domes on main buildings covering the 36-in. and 12-in. refractors are shown
2. Mt. Palomar observatory in California. Installation of the observatory's 200-in. reflecting telescope was postponed for the duration of World War II
3. The McMath-Hulbert observatory of the University of Michigan. Located near Pontiac, Michigan, and devoted to solar work. The smallest dome houses a 24-in. reflecting telescope. The middle tower contains a coelostat and the tower-type solar telescope with a 30-ft. spectrograph. The highest tower also houses a coelostat and tower-type solar telescope
4. Mt. Wilson observatory, near Pasadena, Calif., established in 1904–05. Its largest reflecting telescope, completed in 1917, has a mirror 100 in. in diameter
5. Yerkes observatory of the University of Chicago, at Williams Bay, Wisconsin, completed in 1897. View from the southwest
6. The W. J. McDonald observatory. Dome of the 82-in. reflecting telescope at Mount Locke, Texas. Founded in 1939 jointly by the University of Texas and the University of Chicago

OBSERVATORIES OVER THE WORLD

1. Dome of the 48-in. reflecting telescope of the Astrophysical observatory near St. Michel, 60 mi. northeast of Marseille, France
2. Royal observatory, Edinburgh, Scotland. On Blackford hill. Established in 1896 in place of an observatory on Calton hill, Edinburgh
3. Office building of the Astrophysical observatory near St. Michel, France
4. General view of the historic building of the Pulkowa observatory in the U.S.S.R., destroyed during the siege of Leningrad in World War II. The Russian government planned to reconstruct the building on the original plans
5. General view of the La Plata observatory at La Plata, Argentina

Three hundred years later, Ptolemy (A.D. 150) compiled a star catalogue, but it is doubtful whether this was from his own observation and, therefore, whether he had an observatory beyond that at Alexandria.

The art of astronomical observation was revived several hundred years later in western Asia when observatories were established at Damascus and Baghdad and one at Mokatta by Caliph Hakim about A.D. 1000. A splendid observatory was built at Maragha in northwest Persia by Hulagu Khan about A.D. 1260, but the most productive was that of the Persian Prince Ulugha Beigh, grandson of the great Tamerlane, who, at Samarcand with his assistants, made a catalogue of stars from observations with a large quadrant in the first half of the 15th century. Later in that century, about 1471, John Müller of Königsberg, better known as Regiomontanus, set up an observatory at Nuremberg, with the help of Bernard Walther of that city, furnished with instruments of his own design, and after his death in 1476, clocks, then a recent invention, were added to the equipment. The first observatory, however, that may be considered a prototype of modern national observatories was that of Tycho Brahe on the island of Hveen. To the building commenced on Aug. 8, 1576, he gave the appropriate name Uranibourg.

Tycho Brahe's Observatory.—This building was of some magnificence and large enough to house Tycho and several young men who lived with him as students or observers. It was furnished with a large quadrant attached to a wall in the plane of the meridian, for to this astronomer is due the credit of appreciating the advantage of size in instruments of this type, and of the principle which is embodied in the mural circle. Here Tycho Brahe with his assistants, one of whom was Longomontanus, a name well known in the science, observed the heavens and produced a catalogue of the positions of more than 1,000 stars. On the death of his patron, Frederick II in 1588, Tycho was deprived of royal favour and income. In 1597 Tycho left Denmark, the observatory at Hveen having been already dismantled.

The invention of the telescope in 1609 opens a new chapter in the history of observatories, and the building at Padua in which Galileo discovered and made the first observations of Jupiter's satellites on Jan. 8, 1610, may be regarded as the first of a new class. Others were created as additions to universities or similar institutions during the 17th century. In 1637, King Christian IV of Denmark established a permanent observatory at Copenhagen, which was completed 20 years later and then placed under the direction of Longomontanus.

John Hevel, or Hevelius, a member of a noble family of Danzig, built an observatory in 1641 in his own house and furnished it with an azimuthal quadrant of 5-ft. radius and a sextant of 6 ft., with which he measured the meridian altitudes of stars, sun, moon and planets, and their distances from one another in the manner of Tycho—that is, with plain sights, believing this to be superior to the newly adopted telescopic method.

Paris, Greenwich and Others.—Hevelius died early in 1687 and his work was not carried on, but by that date there had come into existence the two national observatories at Paris and Greenwich. The former was built in the years 1667–71, according to the plans of Claude Perrault, as an architectural monument. Under the Cassinis and others, it has done much for astronomy. The Royal observatory, Greenwich, was founded in 1675 for the definite purpose of the improvement of navigation. Architectural pride again entered into the design, for Sir Christopher Wren wrote of it to Bishop Fell of Christ Church, Oxford, as built "a little for pomp" referring to the main building. The essential instruments were housed apart, and at the present time, Wren's beautiful creation is merely a small item in its extensive domain.

Few establishments of the kind were erected during the next half century. Mainly because of the occurrence of the transit of Venus in 1769, George III built and furnished the King's observatory at Kew. The improvement in reflecting telescopes by James Short and the invention of the achromatic object glass in the latter part of the 18th century marked the beginning of many observatories that have since become famous. The Radcliffe observatory at Oxford was erected 1771–74 from funds bequeathed by Dr. Radcliffe, a court physician "for charitable purposes," the words being interpreted somewhat widely. Provost Andrews bequeathed a substantial sum for building and endowing an astronomical observatory for the University of Dublin, which was built at Dunsink in 1783, but not furnished with instruments until many years later. An observatory was established and endowed at Armagh in Ulster in 1793, in charge of Primate Robinson, while the most prolific British observatory of the period was that of William Herschel at Bath, Datchet and Slough, successively.

Early Continental Observatories.—Continental observatories established during this period were those of Mannheim (1775), which was transferred to Karlsruhe in 1880, and again to Heidelberg in 1896; Lilienthal founded by Schroter in 1779, and furnished with a reflector made by Herschel; Leipzig where a small observatory existed on the tower of the university in the years 1787–90; Breslau (1790); also one at Seeberg near Gotha, founded by Duke Ernest II in 1788 that was made famous by Zach and Encke. The observatory at Palermo, Sicily, where Piazzi made his famous catalogue of stars, was founded in 1790; and at about the same time Lalande and his assistants were observing transits of stars from an observatory in l'École Militaire, Paris.

THE NINETEENTH CENTURY

British Observatories.—A full list of observatories, public and private, founded in Great Britain during this next 100 years would be large. An observatory on Calton hill, founded by a private association, the Edinburgh Astronomical institution, in 1818, was taken over by the crown as a royal observatory in 1834, and transferred to its present site on Blackford hill in the years 1889–96. Cambridge university observatory was founded in 1820 and under its noted directors, George Biddell Airy, James Challis, John Couch Adams, Robert Stawell Ball and Arthur Stanley Eddington has done valuable work, and now well equipped with instruments, has a solar and astrophysical observatory. The Radcliffe observatory at Oxford was originally in the charge of the Savilian professor of astronomy but this arrangement lapsed and the offices of professor and Radcliffe observer became distinct about 1839. In 1875 the University observatory came into existence largely through the liberality of Warren de la Rue, for the use of the Savilian professor. The work of this observatory has been largely photographic. An observatory was established at Liverpool mainly for the time service of the port in 1838, and at Glasgow a small observatory attached to the university, of which Dr. Alexander Wilson had been the first director about 1760, was enlarged and transferred to a new site in 1836.

Among private observatories the reflecting telescope with 6-ft. mirror made by Lord Rosse and set up at his seat, Parsonstown, Ireland, in 1845, is famous, and scarcely less so are the smaller instruments of the same type made by William Lassell, and used by him at Liverpool 1844–52.

Observatories established in England in the second half of the 19th century were those of De la Rue, a pioneer in astronomical photography, at Cranford in Middlesex; of George Knott at Cuckfield, Sussex; of William Huggins, the famous spectroscopist, at Tulse hill, the private observatory of Norman Lockyer, who afterwards developed spectroscopic research at a state-supported establishment at South Kensington. Those of Edward Crossley at Halifax, Yorkshire, and Thomas Espin at Towlaw, Durham, have reputations based on double-star observations.

Colonial Observatories.—A feature of the 19th century was the establishment of British Colonial observatories. Acting on the proposal of the Board of Longitude in 1820, the Lords Commissioners of the Admiralty resolved to establish an observatory at the Cape of Good Hope for the improvement of practical astronomy, which came into being in the year 1829, and has adequately fulfilled its purpose as a government observatory under the directorship of Frank Maclear, Edward James Stone, David Gill, George Washington Hough and Harold Spencer Jones of the present day. This observatory has a reversible transit circle of the latest type, and a heliometer and an equatorially-mounted twin telescope with objectives 24 in. and 18 in. in aperture for photo-

graphic and spectroscopic work—gifts of Frank Maclear.

The first observatory on Australian soil was one on Dawes point, the headland on which stands the present Sydney observatory, established in 1786. In 1853 Robert L. Ellery was appointed to superintend an astronomical observatory at Williamstown which was removed to Melbourne in 1861–63. With the observatories of Sydney and Perth, Melbourne has taken a share in the international work of charting the heavens by photography, and in addition meridian observing, magnetism, seismology, meteorology and time service form its activities. The Adelaide observatory was not completed until 1861. The observatory of Western Australia at Perth was established 30 years later. The aim of a small observatory established at Wellington, New Zealand, under Sir James Hector in 1869 for time service was later enlarged and the institution is now called the Dominion observatory.

Continental Observatories.—During this period many observatories were established on the continent of Europe, two of which were made famous by the labours of Wilhelm Struve. The University of Dorpat, Livonia, Russia, possessed in 1809 an observatory of small dimensions, scantily equipped, of which Struve, a student of astronomy in the university, was given charge in the year 1813. His successful work attracted the attention of the Russian government, and soon the observatory was furnished with such instruments and pecuniary means as to raise it to the rank of a first-class establishment, where Struve, almost single-handed, produced results of a very high standard. Attracted by Struve's work the Emperor Nicholas in 1833 resolved to erect a central observatory for the empire of Russia, and, largely to Struve's design, an observatory was completed in 1839, at Pulkowa near St. Petersburg, which was considered to be the finest and best equipped of the time. Another observatory of the first half of the 19th century, though not on the magnificent scale of Pulkowa, but associated with the name of a distinguished astronomer, was that of Königsberg, established by the king of Prussia in 1813 and put in the charge of F. W. Bessel who had already made a reputation at the observatory at Lilienthal. The observatory at Altona near Hamburg, completed in 1823, was made famous because of its association with Heinrich Christian Schumacher, to whose personality is ascribed the encouragement given to astronomy by the Danish government. In 1874, this observatory was transferred to Kiel, which had then become the chief German naval station, and formed the international central bureau for distribution of astronomical information until World War I, when this useful work was transferred to Copenhagen.

The Royal observatory at Berlin had its origin in the year 1705. It was with the 9-in. refractor of this observatory that the planet Neptune was first seen. The establishment of an observatory at the University of Bonn was decided on by the king of Prussia, in 1836, and Friedrich Wilhelm Argelander, who had been director of the Abo observatory, Finland, transferred to Helsingfors in 1837, was chosen as director. Although the instruments of this observatory are not large, the stupendous work of Argelander, carried on by his successors, in star cataloguing, indicates its principal branch of activity. The University of Strasbourg has an observatory attached to it completed by the German government in 1881, consisting of three magnificent buildings placed in a large open garden. Its largest telescope, the great equatorial, a refractor with object glass of 20-in. aperture, is said to have been the largest in Germany at the time of its erection. The University observatory, Vienna, built on a new site in the years 1874–80 to replace one that dated from the middle of the 18th century, is a large structure standing in grounds of 14 acres in extent, with an imposing façade and surmounted by four domes designed on the model of the Berlin observatory. Basle (1874), Bordeaux (1879), Breslau (1790), Budapest (1856), Cracow (1791), Kazan, Leipzig (1790, remodelled in 1861) are other universities of Europe that have observatories attached to them. At Heidelberg (Königstuhl), a private observatory founded by Dr. Max Wolf in 1877, was merged with Grand-Ducal institute, established in 1898, which combined two sections; one an astrometric observatory that had existed successively at Schoetzingen, Mannheim and Karlsruhe since 1762 (*v. supra* Mannheim), and an astrophysical observatory under the direction of Dr. Wolf.

Among the notable observatories in northern Europe established two or more centuries ago but greatly expanded in later years is the Stockholm observatory, founded in 1748, and now equipped with a large double equatorial telescope, a 40-in. reflecting telescope and many modern auxiliary instruments; the observatory of the University of Upsala founded in 1739; the Royal observatory of Lund, first established in 1670; and the University observatory of Copenhagen originally built about 1650 on the summit of the famous "round tower."

Before World War I there were ten French national observatories under the control of a consultative committee that reported annually to the government. The Paris observatory of the 17th century has been mentioned. Some that were resuscitated or created in the ten years after the war of 1870–71, have history behind them. An observatory at Marseilles, founded by the order of Jesuits about the year 1700, was taken over in 1749, after the expulsion of the Order, as the Royal Naval observatory and made famous by Jean Louis Pons, Pons Joseph Bernard, Adolphe Gambart, Jean Valz and Jean Chacornac. A new observatory was built in 1862 with which the older one was incorporated and the names of Jean Stephan, Jérome Coggia and Alphonse Louis Nicolas Borrelly recall many discoveries of minor planets and comets made with its instruments. The observatory at Toulouse had a predecessor as early as 1718, but the existing establishment dates from about 1840 when it was erected and supplied with excellent instruments at the public expense, but with an inadequate staff, so that it was devoted for many years solely to meteors and meteorology.

The observatory at Bordeaux, together with those at Paris, Toulouse and Algiers, has taken a share in the international work of charting the heavens by photography. The Algiers observatory, about half a century old, is an imposing group of buildings set up on a hill at Boudzareah, near Algiers. The two observatories that complete the ten are the solar physical observatory at Meudon near Versailles and the observatory at Nice, bequeathed by the founder to the University of Paris in 1899 and now ranking as a national institution.

American Observatories.—The first American observatory is said to have been erected at Chapel Hill, N.C., in 1831–32. It was destroyed by fire in 1838. Projects for observatories were set on foot at Williams college, Mass., in 1836; at Hudson, O., 1836–37; and for the National observatory at Washington which was actually established by Lieut. J. M. Gilliss of the U.S. navy in 1843–44. The movement was encouraged and in many cases observatories were created by collective financial help. By the efforts of Prof. D. M. Mitchel money was raised for shares in a public company to build an observatory at Cincinnati. The first meeting of stockholders was held on May 23, 1842, and an object glass 11 in. in diameter, which was quite large for that epoch, was procured during the summer. The Litchfield observatory of Hamilton college, New York, was founded by public subscription in 1852. An observatory attached to the University of Missouri in 1853 was afterwards improved by a gift from Dr. S. S. Laws. In 1856, the Dudley observatory, Albany, was established by gifts from citizens of that city, and took its name from the largest donor, Mrs. Blandina Dudley. The Allegheny observatory was founded as an annex to the university in 1860, and was completed in 1867 through the liberality of W. Shand. The Dearborn observatory of the University of Chicago was built in 1864. The Halsted observatory, attached to Princeton university, came into existence in 1866. The Leander McCormick observatory of the University of Virginia (1883), Washburn observatory of the University of Wisconsin (1878), Michigan University observatory, Ann Arbor (1855), and other university observatories are used both for purposes of education and for astronomical research.

The U.S. Naval observatory at Washington is somewhat akin to Greenwich, since it is a nationally-supported institution for the purposes of the navy. Chronometers and compasses are tested, and the staple astronomical work has been the making of star catalogues and astronomical calculations. One of the most famous of these observatories of the 19th century is that of Harvard college, Cambridge, Mass., whose origin is associated with the

personality of William Cranch Bond, a member of a Cornish family that emigrated in 1786 and settled in Portland, Me., where he was born in 1789. Bond had great aptitude for scientific research, especially astronomy, and when, in 1837, it was decided to build an observatory for Harvard college, he, though engaged in a profitable manufacturing business, accepted the invitation to take charge. No salary was attached to the office until the year 1846. The original Harvard observatory (Dana House, 1839) and the new observatory (1843–47) were established by public subscription. Under the direction of Prof. E. C. Pickering, the work of this observatory was mainly photometric and spectroscopic. Harvard had no telescope of size, until the new observatory was furnished with a 15-in. equatorial telescope, one of the two largest made up to that time. Later a refracting telescope of 24-in. aperture was added, the gift of Miss Catherine Bruce. It had a branch observatory in Arequipa, Peru, at a high elevation in the Andes, built and largely supported by a sum of money bequeathed for the purpose by Uriah Boyden, but this branch was in 1928 transferred to South Africa. Yale university has an observatory, founded in 1882, which is known for its work on the determination of stellar parallaxes and theoretical astronomy. The private observatory of Percival Lowell at Flagstaff, Arizona, has attracted attention because of the observations of the surfaces of the planets made there, for which it was founded in 1894.

In South America, there had been an observatory at Buenos Aires in 1822, whose period of activity was short, so that the National observatory at Santiago, Chile, may be regarded as the first permanently founded (1856) on this continent. The National observatory of the Argentine republic, established at Cordoba in 1870, has done good service in cataloguing the stars of the southern hemisphere. It now has a 60-in. reflecting telescope. There are other observatories in South America.

The last quarter of the 19th century may be said to have seen the beginning of the era of the large telescope, though the large specula of Parsonstown (6 ft.) and Melbourne (4 ft.) were earlier. The 26-in. refractor at Washington dates from 1873, but a few years later, a telescope was made on a considerably larger scale through the benevolence of James Lick, who died in San Francisco on Oct. 1, 1876. This telescope, with object glass 36 in. in diameter, is set up in an observatory on Mt. Hamilton, Calif. In 1895 a reflector with a silver-on-glass mirror of 36-in. diameter, that had been used by Dr. Common, was presented by Edward Crossley of Halifax, England, and with these two instruments and others, the Lick observatory, dedicated to the University of California, has done much photographic and spectroscopic observation. The size of the larger instrument was surpassed ten years later when, in Oct. 1897, through the efforts of Dr. George Ellery Hale, C. T. Yerkes presented a refracting telescope with object glass of 40-in. aperture, together with a large observatory building containing it on the shore of Lake Geneva, Wis., to the University of Chicago. From that date the Yerkes observatory has been a centre of astronomical activity. The program has been, to a great extent, spectroscopic and astrophysical but micrometrical work on double stars, planets and satellites, has had a place, together with work in connection with the discovery and observation of comets.

TWENTIETH CENTURY

Modern Observatories.—The names and locations of active and inactive observatories are printed yearly in the *American Ephemeris and Nautical Almanac*. The progress of astronomy and the changes in the aim of celestial research have brought changes in the characteristics of observatories. At the beginning of the 19th century the equipment of an observatory may be said to have consisted of a meridian instrument with an equatorial as subsidiary; today the latter is generally the more important instrument, and usually is supplemented by photographic equipment and numerous auxiliary instruments. The routine determination of the positions of sun, moon, the planets and stars, however, still continues as standard work at Greenwich, Washington and other national observatories, since such records are necessary for the maintenance of fundamental astronomy.

Outstanding facts of the 20th century have been the making of large telescopes, in some cases of novel design for special researches, and the establishment of branches to existing observatories in places considered more suitable meteorologically than those of their parents. One important example is the observatory set up in 1904–05 on Mt. Wilson, 5,700 ft. above sea level, near Pasadena, Calif. This observatory was established by Dr. George Ellery Hale as a department of the Carnegie Institution of Washington, D.C. The telescopes are on Mt. Wilson where the observations are made. The library, laboratory, administrative offices, and machine shop are in the valley below. For solar observations two tower telescopes—one 150 ft. high and one 60 ft. high—are used. A revolving mirror known as a coelostat and a fixed mirror on the top of the tower reflect the sun's light through an object glass downwards. In each of the towers the spectrograph is mounted in a well under the tower, the depth of the well being one-half the height of the tower. With these instruments a continuous photographic record of the sun's surface is maintained day after day. This observatory has two large reflecting telescopes, one having a mirror 60 in. in diameter and one with a mirror 100 in. in diameter, the latter being the largest (in 1945) in use in the world. The 100-in. mirror is carried on an equatorial mounting and has an interferometer for measuring the diameters of stars. Optical arrangements for both telescopes provide for the use of different focal lengths in the Newtonian, Cassegrain, or coudé form. Further equipment includes a horizontal solar telescope, a 50-ft. interferometer, a 20-in. reflector, and a 10-in. and a 5-in. photographic refractor.

Another large American observatory is the McDonald observatory of the University of Texas. Established in 1939 on Mount Locke, 6,828 ft. above sea level, in the Davis mountains of Texas, it was organized under a co-operative agreement between two universities, in which the University of Texas built the observatory and the University of Chicago provided the scientific staff. The mirror is 82 in. in diameter and is mounted in a telescope of the cross-axis type, with the tube situated on the side of the polar axis. There is a prime-focus camera used for direct photography at the focus of the 82-in. mirror, without other reflections such as are common in a Newtonian telescope. A second camera provides for direct photography at the Cassegrain focus. Spectrographic equipment includes a slitless spectrograph for low-dispersion, spectra, a spectrograph for use at the Cassegrain focus and a coudé focus spectrograph for high-dispersion spectra. The program at McDonald is mainly spectrographic.

Mount Palomar Observatory.—This observatory, which had not yet (in mid-1945) been formally named, was established by the California Institute of Technology to which the International Education board of the Rockefeller foundation made a grant in 1929 for the construction of a 200-in. reflecting telescope. Its operation is under a joint co-operative plan between the California institute and the Mount Wilson observatory of the Carnegie institution. Its location is on Palomar mountain in southern California about 100 mi. distant from Pasadena and Mount Wilson, at an elevation of 5,600 ft.

The dome and building for the great telescope were erected in 1938. The dome, which is 137 ft. high and of about the same diameter, is insulated throughout to protect the telescope from change of temperature when not in operation. The building which supports the dome has three floor levels on which are offices, photographic rooms, air-conditioning units, electrical switchboards and motors, and a large vacuum chamber for aluminizing the 200-in. mirror.

In the centre of the building, rising to the height of the third or operating floor, is the heavy structural steel framework which supports the two pedestals carrying the telescope. The frame or yoke in which the tube rests is rectangular in shape with tubular side members 10 ft. in diameter. A unique feature is the horseshoe-like form of the north member of the yoke which permits the telescope to be turned northward as far as the north pole. The lower surface of this member is accurately faced and serves as the north-bearing surface of the telescope mounting. The tube and frame, weighing a total of about 500 tons, are carried on a system of bearings employing high-pressure oil pads which nearly

eliminate friction and provide remarkable ease of motion.

The tube, 22 ft. in diameter, is designed to avoid angular deflections at its ends and thus to reduce injurious effects of flexure. Uniform driving of the telescope is accomplished by a synchronous motor fed by current generated by a vibrating string standard and suitably amplified. The major portions of the mounting including the oil-bearing system have been erected and tested.

The disk for the 200-in. mirror is a single block of "pyrex" glass cast by the Corning Glass works. It consists of a surface plate about 6 in. thick supported by a network of deep ribs. An opening 40 in. in diameter is cast in the centre of the disk. The mirror, which will weigh about 16 tons when completed, was brought to a spherical form in 1938, more than 5 tons of glass being removed in the process. The slow and difficult work of parabolizing the surface was then commenced but was interrupted by the outbreak of World War II. It was estimated that about one year would be required to complete the parabolization and to figure the auxiliary mirrors to be used in conjunction with it. The finished telescope may be used in any one of three forms: Newtonian or primary focus with a focal length of 55 ft.; Cassegrainian combination, equivalent focal length 267 ft.; coudé combination, equivalent focal length 500 ft.

In addition to the 200-in. telescope under construction, the Palomar observatory has in operation an 18-in. telescope of the Schmidt type and several smaller instruments. A 48-in. Schmidt telescope working at ratio F/2.5 and utilizing a 72-in. concave mirror is also being built. The mirror for this powerful telescope has been completed and the dome erected.

Other Observatories.—Canada has a 72-in. reflector at the Dominion Astrophysical observatory established in 1916 at Victoria, B.C., as a branch of the Dominion observatory at Ottawa, which itself had grown from a modest establishment used by the survey department. The telescope has been devoted chiefly to astrophysical work. In 1935 this size was surpassed by the 74-in. pyrex mirror at the David Dunlap observatory of the University of Toronto. In spite of a rigorous climate this reflector has performed admirably.

In the eastern hemisphere an observatory specially adapted for solar investigation was established at Canberra by the federal government of Australia as a link in the chain of such institutions round the world, of which the Solar Physics observatory at Cambridge, England (removed from South Kensington in 1911), and that at Kodaikanal, southern India (which was established as a government institution about 1900 and replaces, in part, the observatory of the government of Madras founded in 1792) are others. A site has been chosen in southwest Africa under the auspices of the Smithsonian institution of Washington for a station for the special study of solar radiation. The Harvard southern station has been transferred from Arequipa in Peru to Mazelspoort, 14 mi. from Bloemfontein, Orange Free State, Union of South Africa. At this station is one of the two 60-in. telescopes in the southern hemisphere. The second is at the National observatory, Cordoba, Argentina. Yale University observatory has set up a southern branch at Johannesburg; and the Detroit observatory of the University of Michigan has done the same at Bloemfontein through the aid of a generous donor. The principal instrument is a refractor of 27-in. aperture, which is used mainly for observing double stars. In the same connection it may be noted that the observatory of the Union of South Africa at Johannesburg which dates under its present name from 1912 (having previously been known as the Transvaal observatory, when it was mainly a meteorological station) has a 26-in. refracting telescope. The observatory at Durban, in charge of the colonial government of Natal, was closed in 1912. The dome and mounting for a 74-in. reflecting telescope of the Radcliffe observatory, Oxford, have been erected at Pretoria, South Africa, but completion of the mirror in England was delayed by war conditions. In 1942 the New National Astrophysical observatory in Tonanzintla, Mexico, was dedicated. Its principal instrument is a 22-in. reflecting telescope of the Schmidt type.

Some notable additions were made to the observatories of Europe in the first quarter of the 20th century. As the climate of Pulkowa was considered to be unfavourable for observation, through the influence of Oscar Backlund, who was its director for 21 years, branch establishments were founded—one at Odessa in 1898 for the astronomy of position; another at Nicolaieff, 75 mi. from Odessa, in 1912, for a similar purpose; and a third at Simeis in the Crimea. Backlund died in 1916, but in the last few years of his life the Russian government sanctioned the expenditure of large sums of money for the purpose of procuring astrophysical and astrophotographic equipment for the new observatories, and during 1926 a reflecting telescope with a mirror one metre in diameter and a photographic refractor with an objective of 41-in. aperture were supplied to the Simeis observatory by a British firm. The observatory of Geneva, which is of very early foundation (1772), now possesses a reflector with mirror, one metre in diameter, the gift of a member of the staff. The Astrophysical observatory at Potsdam, which dates from the year 1878, was enriched by the addition of a 32-in. photographic refractor in the year 1899, and in 1921 a tower telescope was erected in its grounds as a tribute to Prof. Albert Einstein. The building is modern and original.

A tower telescope has been set up at the Royal Astrophysical observatory at Arcetri (Florence) designed for solar observation. A new object glass was supplied to this institution in 1925 by the German government, by way of war reparation. The Italian Royal observatory at Milan, with which the name of Gíovanni Virginio Schiaparelli is associated, has been removed and improved by the help of resources similarly supplied. The observatory at Bergedorf, Germany, five miles south of Hamburg, developed out of a local school of navigation in the city of Hamburg. Contributions by the citizens for instruments enabled the school to grow into the Hamburg municipal observatory. In 1906 it was transferred to Bergedorf and the new establishment was completed in 1909. This observatory continues to do star-cataloguing work and supplies a time service for the city, but it is well equipped for astronomical observations of other kinds. It has a reflector, one metre in aperture, and a large twin telescope for photography. This observatory has been specially successful in the discovery of comets.

In Great Britain, the Norman Lockyer observatory, originally the Hill observatory, is on the top of Salcombe hill near Sidmouth, Devon. This observatory, at a height of 560 ft., contains instruments from the observatory of the late Dr. Frank McClean at Rusthall, near Tunbridge Wells, and others used at the government establishment formerly at South Kensington. The spectroscopic classification of stars and the determination of their parallaxes from examination of their spectra, are items in its program.

An observatory of an unusual type was established in France in 1930 by Bernard Ferdinand Lyot of Meudon, who set up his apparatus on the Pic du Midi in the Pyrenees mountains at an elevation of 9,300 ft. Here, with a special refracting telescope and optical system of his own design, he obtained remarkable results in the photography of the solar corona, prominences and spectrum of the corona in full sunlight. Using a cinematograph, he was able to record the movements of the prominences by means of motion pictures. A station of the Harvard College observatory using equipment of a type similar to that of Lyot was established at Climax, Colo., in 1940.

The effect of World War II upon observatories was twofold; in some cases invasion and physical damage ended all scientific work at least temporarily; in other cases reduction in operating staffs and transfer of research to war problems limited normal activity. Many observatories in continental Europe and some in England were damaged, and two great Russian observatories, Pulkowa and Simeis, were almost totally destroyed. The condition of numerous others was still (in 1945) unknown. Plans were initiated, however, for the construction of several new observatories and the expansion of others at the close of the war, especially in eastern and western Europe and some parts of the United States.

OBSERVER CORPS IN AIR DEFENSE. World War I, England.—At the beginning of world war hostilities in 1914, the necessity of an air-raid warning service was hardly envisioned, but it was not long before the importance and desirability of such an observer system to transmit intelligence of enemy aircraft activity became evident in the British Isles. Flash warnings, it was obvious, would prove invaluable for air defense as well as to centres about to be attacked.

At first in Great Britain the defenses were limited to telephone reports to the admiralty from police within 60 mi. of London. In 1915 the system was extended to cover England and Wales, with reports telegraphed by local chief constables to the admiralty, which then informed the war office.

In 1916 the war office took charge, a more efficient system of observers was introduced with cordons of 30 mi. outside vulnerable areas, while London was provided with two cordons and coastal posts were established. In the autumn of 1917 the London air defenses were reorganized under General Ashmore. The aeroplane patrol improved steadily, but information from the observers as to enemy aircraft operations was not yet quick enough or reliable enough to aid the defensive pilots. German activity early in 1918 being confined to London and its south and east, a new system was devised: the attacked areas were covered with the various units of the defense, coastal posts, squadrons, guns, searchlights and balloon aprons. These units reported activity of the enemy aircraft, the information filtered through certain centres and then was added to a big map in headquarters. All report message lines were open during operations and no connections were necessary. Extensive telephone construction work was not completed until after May 19, 1918, the date of the last air raid.

Air defense revival early in 1924 found large vulnerable areas without observers; despite the simplicity of demands by the service, intelligence reports would be lacking on enemy aircraft movements over Great Britain. Therefore the country was covered by watchers in series of observation posts, six to eight miles apart, equipped with complete telephone service. The year 1924 saw the first experimental operation around Cranbrook, the reporting centre. It proved the system feasible, and valuable experience was gained.

In 1925 the system was extended to two zones covering the whole of Kent and Sussex, each zone consisting of a network of observer posts with lines to a local centre and then to the headquarters of the air defense. Chief constables and special constables manned the equipment, and the R.A.F. tested the layout by day and night operations. As a result the organization received the official sanction of the home office and the war office, and by 1927 the system embraced Hampshire, Sussex, part of Surrey, Kent, Essex and half of Suffolk. Observers, without pay, were efficient and alert.

World War II.—Air raid defense or the protection of the civilian population caused both Allied and axis governments grave concern, so much so that in 1938 German, Swedish and British civil defense personnel were working together in and around the dockyard towns on the Medway in England and witnessing exercises carried out with a view to saving life and dealing with casualties. The Germans provided much better shelter than the British, but Britain was *facile princeps* in its fire-fighting organization.

Before World War II, Sir John Anderson (later home secretary and minister of home security in Great Britain, 1939–40) lectured to the Imperial Defense college and to the staff colleges on air raid precautions. People with foresight began to think of the future safety of Great Britain and the commonwealth, and passive defense, air raid precautions or civil defense, the new baby of national defense services, was born. It was not at first a popular step and roused little public interest; during the first year of World War II, before the heavy bombing attacks on Great Britain began, quite a large percentage of citizens almost suggested scrapping the carefully built civil defense organization. The cabinet and the home office meanwhile had deputed to a dozen regional commissioners the duty of co-ordinating civil defense, and these chosen deputies used that time as one of valuable training for fire fighters, rescue and decontamination squads, stretcher bearers, ambulance drivers and attendants, air raid wardens, repair parties, control and reporting personnel, etc. Preparation was made for dealing with the damage to water mains, gas, sewerage and electric light installations.

The shelter problem necessitated the appointment of a special regional commissioner in London. Generally speaking, adequate shelter was provided by local authorities, but some of the boroughs failed to provide proper shelter and since the deep-shelter policy was turned down by the government as too costly to provide or, for a variety of reasons, an impossible undertaking, basements, surface shelters, underground tube station shelters, etc., were put under central control. Bunks were constructed and made available for distribution, priority of supply being given to the crowded East End boroughs. In recasting the shelter problem, the community was impressed with the need for dispersal as opposed to crowding thousands together in large communal shelters. Some of the bigger shelters were hit, and the casualties were heavy.

Civil defense in Britain was a community business on a territorial basis. Local government was mainly responsible for recruiting its members, acquiring its vehicles, establishing its depots and control centres and, largely, for its training and administration. Usually the town clerk, the chief local government official, was appointed official civil defense controller. In some cities and towns this duty was taken over by the chief constable.

Air raid defense from the civil viewpoint was concerned firstly with saving life, limb and suffering. Property generally came second, but industries, utility services and food supplies had high protection priorities, and it was the duty of the regional commissioners to ensure the minimum interference with production, war effort, health, morale and the education and upbringing of youth. Civil defense, when faced squarely, became a matter of common sense. Expert opinion helped in matters of shelter construction, protection against blast and splinter effect, fire fighting and the strengthening of buildings and special protection of such key points as power stations, pumping stations and communication centres. Water supplies for fire fighting during large-scale attacks were not at first up to requirements. The defect was overcome later by the building of an elaborate system of static water tanks and reservoirs.

British National Fire Service.—The National Fire service, built to start with on the peacetime fire brigade system, was enlarged by what was first called the Auxiliary Fire service, comprising thousands of men and women. The National Fire service built up a vast network of controls which extended and co-operated throughout Britain, and developed a new, highly disciplined fire organization that was visited by the fire services of the United States, Canada and other Allied countries, whose representatives worked with the National Fire service for weeks at a time before going back to their own lands armed with experience of wartime fire fighting.

There were 1,725 fires in the city of London on Dec. 8–9, 1940, and 780 serious fires on Dec. 29, 1940, when the Guildhall was damaged and eight Wren churches were destroyed.

On March 19, 1941, there were 1,880 fires within the London region. The heaviest "fire blitz" occurred on the night of April 16, 1941, when there were no fewer than 2,251 fires, mainly in Chelsea, Westminster and Lambeth. On May 10 there were 2,154 fires in the centre and West End of London. The fire blitz then began in Liverpool. Following the London fire blitz of Dec. 1940, the government ordered compulsory fire fighting by civilians. Ellen Wilkinson (parliamentary secretary for the ministry of home security 1940–45) took over the general direction of the fire guard, and between the National Fire service and the wardens' service millions of men and women were trained and exercised until fire watching and fire fighting became part of air raid defense.

Civil Defense Services in Britain.—More than 1,000,000 people were enrolled in civil defense in Great Britain. In London alone, excluding the fire guard, nearly 250,000 people were en-

rolled to man the different services. The air raid wardens were the "front line soldiers" of the blitz; a very great proportion of them were volunteers or "part-timers." Wardens' work included a greater variety of duties than fell to the lot of any other civil defense service. The control room staff—operators, messengers, teleprinter girls, tally board and plotting clerks and the representatives of the heads of services—were in the charge of a selected deputy who supervised the reports from the wardens; the staff dissected them and dispatched the requisite aid. Members of the rescue party services were mainly builders' workmen, trained to lift steel girders and shift masonry and concrete blocks. They tunnelled under the debris of demolished buildings and cleared a way for the stretcher bearers. The rescue parties had their trucks fitted with standard equipment: jacks, levers, pulleys and tackle, wire and hemp rope, acetylene cutting plant, shores, sheer-legs, picks, shovels, axes and tools enough to satisfy most lifesaving and demolition requirements. The ambulance service was mostly run by women in civil defense. In London alone this ambulance service conveyed 93,524 casualties to hospitals and 609,783 inter-hospital patients. Other uses were made of this form of transport, and nearly 1,000,000 repair workers were carried for first aid to bombed buildings.

Closely associated with the ambulance service were the mobile hospital units of the field hospital type, usually with a crew of eight: medical officer, qualified hospital nurse, five assistants and man driver. Included in the casualty services were first-aid posts situated in places selected according to density of population and distance from hospitals. Hospitals, their size and capabilities were all worked into the civil defense plan, as were rest centres and mobile supporting columns, consisting of rescue parties and casualty units equipped to be rushed to any area which, through concentrated bombing, found its resources inadequate. An organization for housing the homeless was included in air raid defense and whether the bombed-out people were to be accommodated for a very short time or permanently proved a very heavy commitment, especially in London, where well over 1,000,000 homes were hit and more than 250,000 destroyed. (E. R. G. R. E.)

The Royal Observer corps was reorganized in 1946, and by 1950 it had a strength of 13,000 men and 2,000 women. (X.)

United States.—In the United States no effort toward creating aircraft warning systems had been made until about 1933. Following the great earthquake in Long Beach, Calif., in 1933, when the sheriff of Los Angeles county, Eugene W. Biscailuz, found he was without communications to the stricken area 20 mi. away, an organization for communications in event of disaster was formed. From this evolved the civilian aircraft warning service, utilizing networks of observations and detection of possible enemy aircraft over areas 250 mi. from a central point. These points were known as information centres.

The war beginning in Europe in 1939 intensified the study of this subject in the United States. In total war any object in enemy territory is a military target. The army air corps and allied services conducted several blackouts and enemy air raids, simulating as nearly as possible actual warfare.

These exercises were carried out from 1937 to Jan. 1941. The locations covered were southern California, North Carolina, Alabama and the New England area including the metropolitan area of New York. The first air warning exercise to be conducted in the United States was over 9,000 sq.mi. in southern California and central California in 1937; utilizing the Los Angeles county plan, the tests were carried out by the First Wing G.H.Q. air force and the 63rd antiaircraft artillery for two weeks. March field, corps area headquarters, was the theoretical objective of the enemy.

The information centre for southern California was equipped with every means of communication, including telephone, telegraph, county forestry circuit, Edison power and light telephone circuit, teletypewriter circuits, Santa Fe railroad and Southern Pacific railroad telephone and telegraph circuits, commercial radio and amateur wave lenghts in addition to the county short-wave, two-way portable radios under control of the sheriff's office and the army radio network.

A second exercise covering 80,000 sq.mi., comparable to the area of the British Isles and Ireland, was held in 1938. In 1939 the most extensive effort of this type ever attempted in practice involved the entire Pacific coast. Four information centres were set up, two in California, one in Oregon and one in Washington. Army intelligence reported briefly that the service "worked."

From this trial came opportunity to expand further the service. The civil advisory system was inaugurated, operating directly out of the centres, by which information about approaching enemy aircraft was sent directly from communications centre by the sheriff's office to defense industries, aircraft plants, oil, electric and water systems. During exercises, every vital industry within a radius of 250 mi. was given the warning within a few minutes.

In collaboration with the U.S. army, the Los Angeles county system, known as the aircraft warning system, proved so efficient that it was adopted, with slight modifications, by other large concentrations of population in the United States.

For a large-scale national emergency, the nation was divided into four general areas, with communication centres as follows: northeast, Mitchel field, N.Y.; southeast, Tampa, Fla.; southwest, Los Angeles and March field, Calif.; northwest, Spokane, Wash. It was planned to have the intelligence from observation post spotters flow into the centres after first having been directed through filtering stations in each local area.

Under the general plan of the aircraft warning service, the southern California sector information centre was established at Alhambra, a suburb of Los Angeles, with all incoming circuits terminating at this point. There were four outgoing channels of communication, two radio, one telephone and one teletypewriter circuit from Alhambra to March field, U.S. air corps defense headquarters. To inform all officers in the Alhambra information centre simultaneously of the contents of a received "flash message," a translux projector was employed, projecting each message on a moving tape which in turn was reflected on a screen above the operating map. The map itself was a relief scale map horizontally placed and surrounded by a gallery for personnel. It was operated by a control board of 300 individual push buttons for lighting up the courses of invading aircraft.

The purposes of the test were to co-ordinate the communication systems of the various agencies comprising the aircraft warning service and train the observers in the proper procedure for transmission of messages, identification of aircraft, etc.

An aircraft warning experiment was held in the New York-New England region from Jan. 21 to 24, 1941, under the direction of the G.H.Q. air force. A corps of civilian observers, organized under the auspices of the American Legion, worked with the army. The communications network was operated by the American Telephone and Telegraph company and its affiliated companies.

The test was excellently co-ordinated and proved the feasibility of the plan which the army was formulating. As a result of the test an orientation and indoctrination course was held at Mitchel field, L.I., from March 25 to April 13, 1941, during which all knowledge on the subject was weighed and explored with a view to setting up a fixed and standardized aircraft warning service. (H. E. Hy.)

In Sept. 1939 the governor of New Jersey appointed an emergency defense committee. In May 1940 Tennessee and Virginia organized the first state defense councils. By May 1, 1941, defense councils had been established in most of the states and in more than 1,000 communities. On May 20, 1941, the president, by executive order, established the Office of Civilian Defense. The interest of the U. S. public in air raid defense followed the course of the war. At the time of Pearl Harbor, civilian defense had 3,516,600 volunteers and 7,031 defense committees. Two years later there were more than 12,000,000 registered, of whom 5,534,000 were assigned to duty in the protective services. By then the United States had the largest force of civilian volunteers ever formed for war service. Air raid defense included the army, the air force, Civil Air Patrol, state guards, state police, Red Cross and community welfare services. Each had a role and was prepared to carry out its part.

When war was declared, the framework was well under way.

The pattern was that set up in England as a result of experiences there in 1940 and 1941. These demonstrated that the armed forces and the peacetime services of fire, police and medicine were not capable of meeting the impact of the new strategy of total war; that the existing services should be expanded with added equipment and personnel; new services should be added and the individual schooled to take care of himself and his home; and the nation should be mobilized to protect itself.

The OCD (headed by a director appointed by the president), with nine regional offices, was the national organization. Each state had its state defense council and many local councils, of which there were, at the peak, more than 12,000. Every community likely to be attacked organized one. The national government had no authority over the state or local councils. The OCD was a planning and co-ordinating body. The state and local defense councils were the operating units.

OCD set up the Civil Air Patrol, Forest Fire Fighters service, Facility Security program and civilian protection schools. Its training manuals and guidance on gas defense, blackout, dimout, shelters, camouflage, organization, communications, safety measures and the many other problems of civilian defense were followed by state and local councils. It became the research and advisory centre.

The army air force operated the Aircraft Warning service, with about 600,000 volunteers to warn communities of impending attack. To ensure necessary uniformity, the army promulgated an air raid warning system and controlled practice blackouts. The local units had the true responsibility. Operating through a staff, air raid warden, auxiliary police, auxiliary fire, utility repair, road repair, emergency medical and related services and headed by a commander—the mayor, a well-known citizen, or the head of the police department—these people took their task seriously. They knew that if they failed in their mission there was little hope for their community. Each local unit was expected to be strong enough to handle any anticipated attack.

Every community was far short of the fire equipment necessary to handle effectively the fires resulting from even a small attack. To meet this, in Feb. 1942, congress appropriated $57,000,000 for pumpers, hose and other equipment for communities in critical zones, and $43,000,000 for gas masks, helmets, arm bands, medical supplies and miscellaneous equipment for the individuals of the defense corps.

Neither Germany nor Japan was capable of bombing the United States during World War II. How well the civilian defense organization would have kept down the effect of any air raid attack was unknown. Some units performed creditably in local emergencies, which were, in some sense, tests of their efficiency. Experiences elsewhere pointed to many ways in which it might have been improved, yet it accomplished much. It stood out as the greatest example of U.S. mass mobilization, organization and training ever undertaken by volunteers. Communities found a way to unite by themselves for their own welfare. It gathered the people behind the war effort.

After World War II civilian volunteers, serving without pay, were organized as members of the Ground Observer corps, established to supplement coverage provided by radar networks. The civil authorities were made responsible for the administration of the corps, including recruitment, assigning duties, etc., and the air force supervised the tactical operation, including training. The air force headquarters was established at Ent Air Force base, Colorado Springs, Colo. A number of filtre centres were organized as central points to gather information from observers, plot the course of aircraft, pass on the information to the military air defense authorities, etc.

World War II experience and a trial run called Operation Lookout, made in Sept. 1949, indicated that such a system might afford substantial protection.

OBSIDIAN, a glassy volcanic rock of acid composition. Rhyolitic lavas frequently are vitreous, and when the glassy matter greatly predominates and the crystals are few and inconspicuous the rock becomes an obsidian; the chemical composition is essentially the same as that of granite; the difference in the physical condition of the two rocks is due to the fact that one consolidated at the surface, rapidly and under low pressures, while the other cooled slowly at great depths and under such pressures that the escape of the steam and other gases it contained was greatly impeded.

Only a few obsidians are entirely vitreous; usually they have small crystals of felspar, quartz or a ferromagnesian mineral, and when these are numerous the rock is called a porphyritic obsidian.

These crystals have, as a rule, good crystalline form, but the quartz and felspar are often filled with enclosures of glass.

All obsidians have a low specific gravity (about 2·4) both because they are acid rocks and because they are noncrystalline. Their lustre is vitreous except when they contain many minute crystals; they are then velvety or even resinous in appearance. Black, gray, yellow and brown are the prevalent colours of these rocks.

In hand specimens they often show a well marked banding which is sometimes flat and parallel, but may be sinuous and occasionally is very irregular, resembling the pattern of damascened steel.

When crystals are present they generally have their long axes parallel to the fluxion.

Even when conspicuous and well formed crystals are not visible in the rock there is nearly always an abundance of minute imperfect crystallizations (microlites, etc.). They are often so small that high magnifications may be necessary to ascertain their presence. Some are globular and others are rod shaped; they may be grouped in clusters, stars, rosettes, rows, chains or swarms of indefinite shape. In banded obsidians these microlites may be numerous in some parts but few or absent in others. The larger ones polarize light, have angular outlines like those of crystals, and may even show twinning and definite optical properties by which they can be identified as belonging to felspar, augite or some other rock-forming mineral.

These microlites or crystallites (*q.v.*) show that the glassy rock has a tendency to crystallize, which is inhibited only by the very viscous state of the glass and the rapidity with which it was cooled. Another type of incipient crystallization which is excessively common in obsidian is spherulites (*q.v.*), or small rounded bodies which have a radiating fibrous structure. They are of globular shape, less frequently irregular or branching, and may be elongated and cylindrical (axiolites). In some obsidians from Teneriffe and Lipari the whole rock consists of them, so closely packed together that they assume polygonal shapes like the cells of a honeycomb. In polarized light they show a weak gray colour with a black cross, the arms of which are parallel to the crosswires in the eyepiece of the microscope and remain stationary when the section is rotated.

Often bands of spherulites alternate with bands of pure glass, a fact which seems to indicate that the growth of these bodies took place before the rock ceased to flow.

As cooling progresses the glassy rock contracts and strain phenomena appear in consequence. Porphyritic crystals often contract less than the surrounding glass, which accordingly becomes strained, and in polarized light may show a weak double refraction in a limited area surrounding the crystal. Minute cracks are sometimes produced by the contraction; they are often more or less straight, but in other cases a very perfect system of rounded fissures arises. These surround little spherules of glass which are detached when the rock is struck with a hammer. There may be concentric series of cracks one within another. The minute globular bodies have occasionally a sub-pearly lustre, and glassy rocks

which possess this structure have been called perlites (*q.v.*).

Although rocks wholly or in large part vitreous are known from very ancient geological systems, such as the Devonian, they are certainly most frequent in recent volcanic countries. Yet among the older rocks there are many which, though finely crystalline, have the chemical composition of modern obsidians and possess structures, such as the perlitic and spherulitic, which are very characteristic of vitreous rocks. By many lines of evidence we are led to believe that obsidians in course of time suffer devitrification; in other words, they pass from the vitreous into a crystalline state; but since the changes take place in a solid mass, they require a very long time for their achievement, and the crystals produced are of only extremely small size. A dull stony-looking rock results, the vitreous lustre having entirely disappeared, and in microscopic section this exhibits a cryptocrystalline structure, being made up of exceedingly minute grains principally of quartz and felspar. Often this felsitic devitrified glass is so fine-grained that its constituents cannot be directly determined even with the aid of the microscope, but chemical analysis leaves little doubt as to the real nature of the minerals which have been formed. Many vitreous rocks show alteration of this type in certain parts where either the glass has been of unstable nature or where agencies of change such as percolating water have had easiest access (as along joints, perlitic cracks and the margins of dikes and sills). Obsidians from Lipari often have felsitic bands alternating with others which are purely glassy. In Arran there are pitchstone dikes, some of which are completely vitreous, while others are changed to spherulitic felsites more or less silicified.

Obsidians occur in many parts of the world along with rhyolites and pumice. In Europe the best-known localities for them are the Lipari Islands, Pantelleria, Iceland and Hungary. Very fine obsidians are also obtained in Mexico, at the Yellowstone park, in New Zealand, Ascension and in the Caucasus. Included in this group are some rocks which are more properly to be regarded as vitreous forms of trachyte than as glassy rhyolites (Iceland), but except by chemical analyses they cannot be separated. It is certain, however, that most obsidians are very acid or rhyolitic. The dark, semi-opaque, glassy forms of the basic igneous rocks are known as tachylytes (*q.v.*). The typical obsidians exhibit the chemical peculiarities of the acid igneous rocks (viz., high percentage of silica, low iron, lime and magnesia, and a considerable amount of potash and soda) as shown in the following table.

	I Yellowstone park	II Iceland	III Mexico

(J. S. F.)

OBSTETRICS. Obstetrics is the branch of medical science dealing with childbirth, and is concerned with the care of women from conception through pregnancy and labour, and to the completion of the lying-in period, when the reproductive organs have returned to their normal nonpregnant condition. The word itself is derived from the Latin *ob* ("against," "in front of") and *stare* ("to stand"), indicative of the accoucheur in the middle ages, when the attendant stood before the obstetrical chair to receive the child as it was extruded. With gynaecology (*q.v.*), which treats of the diseases peculiar to women, it provides for the care of conditions in, and related to, the female reproductive function. The two subjects are generally taught and practised as a single discipline since their fields are so interdependent and overlapping. There is a growing tendency to begin obstetrical supervision even before conception. In the United States many states make statutory provision for premarital examinations directed particularly at the control of congenital syphilis by preventing the marriage of infected individuals. A more thorough evaluation of reproductive capacity was being demanded by many women before marriage. Such examinations include study of the bony pelvis, the pelvic organs and the organism as a whole for evidence of disease or deformity that might make childbearing unusually hazardous. The old idea that the obstetrician is concerned only with confinement had given way to a newer concept that his duties include all types of supervision necessary to ensure the delivery of a healthy child from a healthy mother.

Pregnancy.—The gestation period in humans averages 280 days from the beginning of the last normal menstrual period, or 266 days from the ovulation which led to conception, assuming that ovulation occurred 14 days before the anticipated period which was missed. Pregnancy is accompanied by significant alterations in the physical economy of the body and by definite mental changes so that the whole body participates. These variations from the nonpregnant normal impose additional stresses which are likely to overload any organ or system that is not completely normal, and may thus lead to serious complications. Not only must the organism provide materials for the growth of the reproductive organs, especially the uterus and breasts, but it must supply the growing conceptus with the elements essential for its growth. These demands become greater as pregnancy advances and the rate of foetal growth increases, and lead to an increasing metabolic strain. The last two or three months constitute the period when these stresses and strains are most likely to disturb the normal body functions. These facts finally forced recognition of the necessity for professional supervision during the greater part of pregnancy; and the development of a program for such prenatal care constituted an outstanding contribution in the field of preventive medicine.

Ante-Partum (Prenatal) Care.—Early in the 20th century there developed an increasing awareness of the need for, and the practical advantages of, medical supervision during pregnancy. This program calls for an initial visit to a physician as soon as pregnancy seems probable, and repeat visits at stated intervals. At the first visit a general physical examination is made with special attention to the pelvic organs and the bony pelvis to determine their integrity and adequacy. In many communities blood is taken for a test for syphilis, for determination of the Rh factor and for routine studies of the haemoglobin and blood cell content. Any apparent inadequacy is subjected to further study. At subsequent visits (every four weeks in the early months to every week in the last month), the weight is recorded, the blood pressure tested, the urine examined and the course of the pregnancy evaluated. The woman comes to know her attendant who assumes the responsibility for advising diet, for regulating physical activity, for treating complaints as they arise and for general supervision aimed at avoiding serious complications and assuring a successful outcome of the pregnancy. Competent authorities ascribe a considerable share of the marked reduction in maternal mortality after 1930 to the beneficial results of ante-partum care, in that it tends to prevent untoward pregnancy manifestations or to detect them in an early stage when they are amenable to treatment.

The pregnant woman is subject to all the diseases and accidents of the average adult and, in addition, is exposed to certain risks inherent in the pregnant state. Among the latter, the most common is abortion (or miscarriage), the expulsion of the conceptus before the period of viability (generally taken as 28 weeks). This may result from causes operative in the mother or the conceptus —spontaneous abortion; from malicious interference with the pregnancy—criminal abortion; or from medical intervention designed to protect the mother's health or life—therapeutic abortion. It is estimated that 10% to 20% of all pregnancies terminate themselves (spontaneous abortion) in the first few months. The most common cause is the failure of some portion of the conceptus to develop properly, its expulsion representing a form of biological economy. The incidence of criminal abortion is not determinable because of the secrecy surrounding its performance, but it has been estimated that 500,000 to 700,000 such illegal procedures were being carried out at mid-20th century in the United States annually. Therapeutic abortion is generally limited

to women with chronic diseases that tend to be aggravated by pregnancy; as the medical treatment of these conditions improves, the reasons for therapeutic abortion become less common. The chief risks in any type of abortion are infection of the uterus and haemorrhage from incomplete separation of the placenta. Under the influence of therapy with antibiotics and blood transfusions, these conditions became much less likely to prove fatal than was formerly the case.

Another inherent pregnancy danger is the possibility of the development of toxaemia of pregnancy, one of several related but seemingly different conditions characterized by hypertension, albuminuria and oedema, which may terminate in generalized convulsions (eclampsia). Toxaemia at mid-century was still one of the three major causes of mortality, but ante-partum supervision had considerably reduced its severity and its death rate. Its cause was still unknown in spite of years of work by many investigators.

Labour.—Labour, the period of parturition, appears approximately 280 days after the onset of the last normal menstruation; variations of two or three weeks in either direction are not uncommon and are usually of no significance. At the appointed time the uterus begins to contract to expel its contents and the contractions are called "labour pains." The process is divided into three (or four) stages depending upon the events transpiring in the birth canal. The first stage, which involves the dilatation of the cervix, the mouth of the womb, is the longest and may last many hours; the second lasts from complete dilatation of the cervix to birth of the child; and the third from then until the expulsion of the placenta (afterbirth). Some authorities include a fourth stage which lasts for an hour or more after birth of the placenta, or until the uterus is thoroughly contracted and the danger of haemorrhage from relaxation of that organ is passed. The entire process may take days, but is generally completed in 12 to 18 hrs. First labours are generally longer than succeeding ones. The primary motive power in all stages of labour is the strong intermittent contractions of the uterine muscle, aided in the second and third stages by reflex or voluntary efforts of the abdominal muscles.

In the first stage the uterine contractions slowly dilate the cervix by pulling it up over the foetal part which is the lowest. Normally this part is covered by the bag of waters, or amniotic sac, in which the child lies. When this sac breaks early, permitting escape of some of the fluid, there is a dry labour. This latter condition was formerly thought to produce long, difficult labours, but it is now recognized that premature rupture of the bag of waters does not materially alter the birth process provided other conditions are normal. In fact, artificial rupture of the sac is widely employed to induce labour when some condition makes it advisable. The child usually descends little during the first stage, especially if the sac remains intact. In the second stage the force of the uterine and abdominal muscular contractions drives the child down, through and out of the birth canal according to certain patterns, the mechanism of labour depending upon the way the child is lying. As the child leaves the uterus, this organ contracts to accommodate to the reduction in the volume of its contents until at the end of the stage its cavity contains only the placenta. The contractions of the third stage separate the afterbirth from its attachment to the uterine wall and then expel it from the canal. In the fourth stage the muscle fibres contract and retract to close off the vessels torn through by separation of the placenta and thus prevent excessive blood loss.

Usually at full term the top of the child's head, the vertex, comes first and this is thought of as the normal position for birth. Occasionally (3% to 4%), the buttocks, or breech, are lowermost, and rarely the child lies crosswise (transverse presentation). A breech presentation is more serious for the child, who may suffocate if not expelled or extracted promptly, while a transverse presentation offers an insurmountable obstacle to the birth of a normal-size child and must be treated by operative intervention. It is common practice to attempt to change a breech or transverse presentation to a vertex by external manipulation before the onset of labour. Failing that, some operative procedure may be required to effect delivery.

Twins occur about once in 80, and triplets once in 6,400 births. Quadruplets and quintuplets are correspondingly still more uncommon. In any multiple pregnancy birth is likely to occur prematurely because of overdistention of the uterus, and the children are generally smaller than normal. It is uncommon for the total weights of the children to exceed 15 to 17 lb. Single children rarely weigh more than 11 lb. (5,000 g.), and the average is about seven and one-half lb.

In the 20th century there was an increasing tendency in most areas to alleviate the pains of labour by the use of analgesic and anaesthetic drugs. Although dozens of drugs, singly and in combination, had been employed by mid-century, none had been universally accepted. The ideal medication which would relieve pain without slowing the birth process or injuring either mother or child had not been discovered. It had become possible, however, to reduce the pain safely to a point where childbearing was not the ordeal it once was.

Delay in the birth process caused either by disproportion between the child and the maternal pelvis or by ineffective pains (uterine inertia) is the most common complication of labour. With modern methods the adequacy of the pelvis can usually be determined before labour, and delivery effected by Caesarean section in those cases where normal birth seems impossible. Under the influence of improved surgical technique, the availability of blood transfusions and the protection from infection offered by the antibiotics, abdominal delivery came to be a relatively safe method of treating such complications. First-stage inertia is combated with rest under narcotics and the maintenance of fluid balance, with Caesarean section available should vaginal delivery eventually prove impossible. Second-stage inertia is managed with forceps or some other form of manipulation.

Haemorrhage during or shortly before the onset of labour is caused by early separation of the placenta which may either be normally implanted well up on the uterine wall (ablatio, or abruptio, placentae), or located over the cervix when dilatation inevitably produces bleeding (placenta praevia). These conditions are dangerous to both mother and child, but especially to the latter who suffers from asphyxia and is, moreover, generally premature.

The third and fourth stages present one of the most serious complications of childbearing—post-partum haemorrhage. Excessive bleeding after delivery of the child is usually due to incomplete separation of the placenta or to failure of the uterus to contract and retract properly after that structure has been expelled. The time-honoured remedies, removal of the afterbirth, employment of uterine massage and administration of oxytocic drugs, are supplemented by blood transfusions. The lifesaving virtues of a hospital blood bank are nowhere better illustrated than in this complication.

Puerperium.—The puerperium, or lying-in period, continues from the end of the fourth stage of labour to the restoration of the pelvic organs to the nonpregnant state—usually six to eight weeks. The necessary anatomical changes occur with extraordinary rapidity; *e.g.,* the uterus, which weighs two pounds at the termination of labour, comes to weigh two ounces after six weeks, and its blood vessels, which carried the burden of nourishing the child for nine months, are replaced by new vessels suitable to this smaller size. Unless the child is suckled, menstruation reappears usually in about eight weeks; lactation may be accompanied by absence of the menses.

It was thought formerly that full recovery of the mother depended upon maintenance of a semi-invalid regimen, ten days or more of bed rest and several additional weeks of restricted activities. The later tendency, especially in the United States, was toward early ambulation and prompter return to normal activity by women with normal pregnancies and labours. It was believed that such a course not only ensured more rapid convalescence but also greatly reduced the incidence of "milk leg," formerly a frequent and serious puerperal complication.

The chief risk during the lying-in period is puerperal fever, caused by the growth of pathogenic bacteria in the wounded areas of the birth canal, especially the uterus. These organisms are

generally introduced from without during or shortly after labour but may occasionally be resident in the birth canal where they are relatively innocuous until presented with the favourable growth conditions developing after delivery. Aseptic surgical technique during labour can largely control exogenous infections but has little effect on endogenous organisms, since it is impossible to sterilize the birth tract. However, both prevention and cure of pelvic infections can generally be effected with antibiotic drugs and repeated blood transfusions.

Mortality.—As late as 1933 the position of the United States among the nations of the world with respect to maternal mortality was far from enviable; the rate that year was 6.2 maternal deaths per 1,000 live births, while Sweden had a rate of only 3.1 and the white population of New Zealand, 4.4. The corresponding rate for England and Wales was 4.5 deaths per 1,000 live births.

After 1933, however, many factors became operative to reduce this largely unnecessary loss of life among women in the prime of life. Ante-partum supervision was expanded to include the majority of pregnant women; intra-partum and post-partum care was improved by the provision of more obstetrical beds in well-regulated hospitals, by the availability of physicians better trained in obstetrical care and the progressive elimination of untrained midwives and by the introduction of chemotherapeutic and antibiotic drugs and of banks for storing blood and blood substitutes. The impact of any one of these factors could not be defined since the death rate declined at a fairly steady rate. From 6.2 in 1933, it fell to 4.4 in 1938, to 2.5 in 1943 and to slightly below 1.0 in 1949 for the United States. Figures available for England and Wales for 1947 showed a rate of 1.2 maternal deaths per 1,000 live births.

It was possibly significant that the greatest percentage drop in maternal mortality was in infected abortions—92%, and in infections during childbirth and the puerperium—84%, while the decrease in toxaemias of pregnancy and the puerperium was 79% and in haemorrhage of pregnancy and of childbirth and the puerperium—66%, the smallest decline in any category. (E. D. P.)

History.—As with the Egyptians and Hebrews, among the Greeks the skilled attendants for women in labour were women. There are indications in the Hippocratic writings (400 B.C.) of his interest in the disorders of females, and his oath forswears the use of abortifacients. In the writings attributed to Hippocrates' followers, some of these subjects are dealt with more fully; but while the physician was sometimes called in to give advice in a difficult labour, he was usually called only in a case where the child was already dead, and then he told how he had to mutilate and extract it. In the medical school of Alexandria, Herophilus (*fl.* 300 B.C.) gave a truer idea of the anatomy of the female than had previously prevailed; other physicians gave evidence of their interest in midwifery and the diseases of women; and Celsus (in the reign of Augustus) reported that surgeons could sometimes bring about the delivery by the operation of turning the infant.

In the middle of the 16th century, Ambroise Paré, a French surgeon, revived the operation of podalic version and showed how the infant could often be saved instead of being broken up and extracted piecemeal. Three sets of compilations, containing extracts from the various writers on obstetrics and gynaecology from the time of Hippocrates onward, were published under the title *Gynaecia*, or *Gynaeciorum*, in 1566, 1586 and 1597. After the middle of the 17th century, more medical men began to publish treatises, and parturient women began to call on men to attend them in natural labours. Heinrich van Deventer, a Dutch obstetrician, in 1701 gave a scientific description of the pelvis, and by 1716 doctors were using the "harmless forceps" with which a living child could be extracted in conditions where formerly the child's life was sacrificed and the mother's life endangered.

In the following centuries, greater strides were made than in all the preceding ages. In the 18th century various universities established chairs of midwifery, and two new operations—symphysiotomy and the induction of premature labour—enhanced the powers of the obstetrician. Two outstanding achievements in the 19th century were the alleviation of the pains of labour by anaesthesia and the arrest of mortality from so-called puerperal fever by antiseptic measures. (X.)

OCALA, a city in the interior of Florida, U.S., 100 mi. S.W. of Jacksonville; the county seat of Marion county. It is on federal highways 27, 301 and 441 and is served by the Atlantic Coast Line and the Seaboard Air Line railways and by Eastern Air Lines. Pop. (1950) 11,741; (1940) 8,986. The city is the centre of mineral deposits having high-quality pure lime and limerock. It was the original centre of the Florida phosphate industry. There are also a crate-box-hamper factory, lumber yards, creamery, meat-packing and fruit-packing plants and building material, concrete pipe, citrus concentrate, shirt and insecticide plants. Five miles E. is Silver Springs (so called from the transparency and refractive powers of its waters), which has a circular basin 300 ft. in diameter and 65 ft. deep and discharges more than 300,000 gal. a minute, its outflow forming a navigable stream 9 mi. long emptying into the Ocklawaha river.

Ocala was settled in 1845 and chartered as a city in 1868. It has a council-manager form of government. The name is Seminole, meaning fertile soil.

OCAÑA, a town of central Spain, in the province of Toledo; on the extreme north of the tableland known as the Mesa de Ocaña, with a station on the railway from Aranjuez to Cuenca. Pop. (1940) 9,806 (mun., 9,953). Ocaña is the Vicus Cuminarius of the Romans, and was the dowry that El Motamid of Seville gave his daughter Zaida on her marriage to Alphonso VI of Castile (1072–1109).

THE OCARINA, A WIND INSTRUMENT POPULAR AMONG STREET PLAYERS

OCARINA, a wind instrument invented in Italy, which is classed with musical toys or freaks. It consists of a vessel in the shape of an egg with a pointed base and perforated with holes and a tube like a spout in the side, containing the mouthpiece. In America, it is sometimes called a "sweet potato."

O'CAROLAN (or Carolan), **TURLOGH** (1670–1738), Irish bard, son of John O'Carolan, a farmer, was born at Newtown, near Nobber, Co. Meath. At 18 he became blind from smallpox. He received special instruction in music, and used to wander with his harp round the houses of the surrounding gentry, mainly in Connaught. The number of Carolan's musical pieces, to nearly all of which he composed verses, is said to exceed 200. He died March 25, 1738, and was buried at Kilronan.

His poetical *Remains* in the original Irish, with English metrical translations by Thomas Furlong, were printed in Hardiman's *Irish Minstrelsy* (1831). Many of his songs were preserved among the Irish manuscripts in the British Museum.

OCCAM, WILLIAM OF (*c.* 1300–1349), English schoolman, known as *Doctor invincibilis* and *Venerabilis inceptor,* was born at Ockham, Surrey, and after joining the Franciscans, studied from 1312 to 1318 at Merton college, Oxford, where he taught until 1324, when he was summoned to Avignon to account for some of his doctrines. While he was confined to his convent, in 1326, John XXII ordered various theses from his works to be examined by the masters of theology, but his works were not actually condemned. Two years later his championship of the Spirituals brought him into a further conflict with the pope, and as a result, he and Michael of Cesena, general of the order, joined the emperor Louis of Bavaria, who was at that time in contest with the papal curia. It was for Occam's share in this controversy that he was best known in his lifetime. Michael of Cesena died in 1342, and Occam, who had received from him the official seal of the order, was recognized as general by his party. He probably died at Munich in 1349, having tried to be reconciled with the church after the death of the emperor.

Occam was one of the most interesting figures in the great contest between pope and emperor, which laid the foundation of modern theories of government, in the disintegration of scholasti-

cism and in the rise of theological scepticism. In the *Opus nonaginta dierum* (1330) (written in reply to John XXII.'s libellus against Michael of Cesena), and in its successors, the *Tractatus de dogmatibus Johannis XXII. papae* (1333–34), the *Compendium errorum Johannis XXII. papae* (1335–38) and in the *Defensorium contra errores Johannis XXII. papae* (1335–39), Occam only incidentally expounds his views as a publicist, the *Compendium* being of special interest because it selects four papal constitutions which involved a declaration against evangelical poverty, and insists that they are full of heresy. The *Super potestate summi pontificis octo quaestionum decisiones* (1339–42) attacks the temporal supremacy of the pope, insists on the independence of kingly authority, which he maintains is as much an ordinance of God as is spiritual rule, and discusses what is meant by the State. His views on the independence of civil rule were even more decidedly expressed in the *Tractatus de jurisdictione imperatoris in causis matrimonialibus,* in which he contends that it belongs to the civil power to decide cases of affinity and to state the prohibited degrees. By 1343 his great work the *Dialogus* (*see* Goldast ii. 398–957), in which he attempted to summarize his views, was in circulation. His last work, *De Electione Caroli IV.*, restates his opinions upon temporal authority.

In philosophy, Occam's most significant doctrines fall within the departments of psychology, metaphysics and theology. In the first, he contends that since singulars alone exist, the universal, which is a kind of mental label, has an objective value only inasmuch as it is thought; that the *intellectus agens* and the *species intelligibiles* are superfluous because abstraction follows naturally upon perceptions or intuition, the fundamental form of human knowledge; that will and not intellect is the primary faculty of the soul, and that both faculties, like memory, are identical with the substance of the soul; and that a *forma corporeitatis* must be admitted if the independence of the soul is to be preserved. In metaphysics, Occam teaches that matter has its own essence apart from form; that accidents are only aspects of substance; that the problem of individuation is meaningless because each thing is singular in itself, and that between essence and existence there is no real distinction. The famous dictum—*Essentia non sunt multiplicanda praeter necessitatem*—has become known as "Occam's Razor," but it was already stressed by Duns Scotus. In theology, Occam's scepticism is especially noticeable in his assertion that the existence of God and His attributes, including His unity and infinity, are not strictly provable. According to Occam, the most characteristic activity of God is willing, and moral laws are good only because God wills them and not in their own right.

Bibliography.—Occam's political works were edited by Goldast (Frankfurt, 1614) and further mss. by R. Scholz (Rome, 1914). The *Dialogus* appeared separately in 1495, the *Defensorium contra Joannem XXII.* in 1513, and the *De Imperatorum et pontificum potestate* in 1927 (edit. C. K. Brampton). Of the non-political works, the *Commentary on the Sentences* appeared in 1483 and 1495, the *Quodlibet* in 1487 and 1491 and the logical treatises fairly frequently in the 15th and 16th centuries.

Full bibliography in Überweg, *Gesch. der Philosophie* (ed. 2, 1928).

OCCASIONALISM, in philosophy, a term applied to that theory of the relation between matter and mind which postulates the intervention of God to bring about in the one a change which corresponds to a similar change in the other. The theory thus denies any direct interaction between matter and mind. It was expounded by Geulincx and Malebranche to avoid Descartes's dualism of thought and extension, and to explain causation.

OCCLEVE (or Hoccleve), **THOMAS** (1368–1450?), English poet, was born probably in 1368/9. What is known of Occleve's life has to be gathered mainly from his works. At eighteen or nineteen he obtained a clerkship in the Privy Seal Office, which he retained on and off, in spite of much grumbling, for about thirty-five years. In 1399 he received a small annuity, which was not always paid as regularly as he would have wished. "The Letter to Cupid," his first poem to which we can affix a date, was translated from *L'Epistre au Dieu d'Amours* of Christine de Pisan in 1402, evidently as a sort of antidote to the moral of *Troilus and Cressida,* to some mss. of which we find it attached. About 1410 he settled down to married life, and the composition of moral and religious poems. His longest work, *The Regement of Princes* or *De Regimine Principum,* written for Prince Hal shortly before his accession, is a tedious homily on the virtues and vices, imitated from Aegidius de Colonna's work of the same name, from the suppositious epistle of Aristotle, known as the *Secreta secretorum* and the work of Jacques de Cessoles (*fl.* 1300) rendered into English later by Caxton as *The Game and Playe of Chesse.*

On the accession of Henry V. Occleve turned his muse to the service of orthodoxy and the Church, and one of his poems is a remonstrance addressed to Oldcastle, calling upon him to "rise up, a manly knight, out of the slough of heresy." Then a long illness was followed for a time, as he tells us, by insanity. His "Dialog with a Friend," written after his recovery, gives a naïve and pathetic picture of the poor poet, now fifty-three, with sight and mind impaired, but with hopes still left of writing a tale he owes his good patron, Humphrey of Gloucester, and of translating a small Latin treatise, *Scite Mori,* before he dies. His hopes were fulfilled in his moralized tales of "Jereslaus' Wife" and of "Jonathas," both from the *Gesta Romanorum,* which, with his "Learn to die," belong to his old age. After finally retiring from his privy seal clerkship, he was granted in 1424 sustenance for life in the priory of Southwick, Hants, on which, with his former annuity, he appears to have lived till about the middle of the century. A "Balade to my gracious Lord of Yorke" probably dates from 1448 or later.

The main interest for us in Occleve's poems is that they are characteristic of his time. They illustrate the blight that had fallen upon poetry on the death of Chaucer. The nearest approach to the realistic touch of his master is to be found in his "Male Regle," which, written about 1406, gives some interesting glimpses of his "misruly youth." But these pictures of 15th-century London are without even the occasional flash of humour that lightens up Lydgate's *London Lackpenny.*

A poem, "Ad beatam Virginem," generally known as the "Mother of God," and once attributed to Chaucer, is copied among Occleve's works in ms. Phillipps 8151 (Cheltenham), and may thus be regarded as his work. Occleve found an admirer in the 17th century in William Browne, who included his "Jonathas" in the *Shepheards Pipe* (1614). Browne added a eulogy of the old poet, whose works he intended to publish in their entirety (*Works,* ed. W. C. Hazlitt, 1869, ii. 196–198). In 1796 George Mason printed six *Poems by Thomas Hoccleve never before printed . . .*; "De Regimine Principum" was printed for the Roxburghe Club in 1860, and by the Early English Text Society in 1897. *See* Dr. F. J. Furnivall's introduction to *Hoccleve's Works; The Minor Poems, in the Phillipps MS. 8151, and the Durham MS. III. 9,* ed. F. J. Furnival; ii. *The Minor Poems in the Ashburnham MS. Addit. 133,* ed. Israel Gollancz; iii. *The Regement of Princes A.D. 1411–12, and fourteen of Hoccleve's minor poems,* ed. F. J. Furnivall (Early English Text Society, 3 vols., 1892–1925).

OCCULTATION, in astronomy, the hiding of one celestial body by another passing in front of it; commonly the passage of the moon or of a planet between the observer and a star or another planet.

OCCULTISM: *see* Magic.

OCEAN AND OCEANOGRAPHY. "Ocean" is the name applied to the great connected sheet of water which covers the greater part of the surface of the earth. But the ocean is less than the hydrosphere in so far as the latter term includes also the water lying on or flowing over the surface of the land. The conception of an encompassing ocean bounding the habitable world is found in the creation myths of the most ancient civilizations. The Babylonians looked on the world as a vast round mountain rising from the midst of a universal sheet of water. In the Hebrew scriptures the waters were gathered together in one place at the word of God, and the dry land appeared. The Ionian geographers looked on the circular disk of the habitable world

as surrounded by a mighty stream named Oceanus, the name of the primeval god, father of gods and men, and thus the bond of union between heaven and earth.

Since the Pythagorean school of philosophy upheld the spherical as against the disk-shaped world, some of the ancient geographers, including Eratosthenes and Strabo, looked upon the hydrosphere as forming two belts at right angles to each other, one belt of ocean following the equator, the other surrounding the earth from pole to pole as in the *terra quadrifida* of Macrobius; while others, including Aristotle and Ptolemy, looked upon the inhabited land, or *oikoumene,* as occupying the greater part of the earth's surface. Until the discovery of America and of the Pacific ocean the belief was general that the land surface was greater than the water surface. (*See* MAP.) Only in the 19th century has the existence of the southern continent been demonstrated within the limits of Antarctica.

Oceanography is the science which deals with the ocean. Of recent years the use of "hydrography" as the equivalent of physical oceanography has acquired a certain currency, but as the word is also used with more than one other meaning (*see* SURVEYING) it ought not to be used for oceanography.

History of Research and Organization.—Research in oceanography began in recent times, especially since the rapid increase in the study of the exact sciences during the 19th century. Observations at sea with accurate instruments became common, and the ships' logs of today are provided with headings for entering daily observations of the phenomena of the sea-surface. The contents of the sailors' scientific logs were brought together by the U.S. enthusiast in the study of the sea, Matthew Fontaine Maury (1806–73), whose methods and plans were adopted at international congresses. Many millions of observations are recorded in ships' logs; this firsthand material is preserved in appropriate offices of various nations. The contents of these logs, it is true, refer more to maritime meteorology than to oceanography properly so called.

This material for the study of the surface phenomena of the ocean has been supplemented in relation to the study of the depths of the ocean, by the records of numerous scientific expeditions and latterly by publications embodying systematic observations on a permanent basis. Valuable observations were made in oceanography during the expeditions of Captain James Cook and the polar explorers, especially those of Sir John Ross in the north and Sir James Ross in the south. The period of deep sea investigation began about 1850 when it became possible to measure ocean depths with precision. (*See* SOUNDING.) At this time, an exact knowledge of the depths of the ocean assumed an unlooked-for practical importance for the laying of telegraph cables at the bottom of the sea. Another stimulus came from the biologists, who began to realize the importance of a more detailed investigation of the life conditions of organisms at great depths in the sea.

These preliminary trips of scientific marine investigation were followed by the greatest purely scientific expedition ever undertaken, the voyage of H.M.S. "Challenger" round the world under the scientific direction of Sir Wyville Thomson and the naval command of Sir George Nares. This epoch-making expedition lasted from Christmas 1872 to the end of May 1876, and gave the first wide and general view of the physical and biological conditions of the ocean as a whole. Almost simultaneously with the "Challenger," a German expedition in S.M.S. "Gazelle" conducted observations in the South Atlantic, Indian and South Pacific oceans; and the U.S.S. "Tuscarora" made a cruise in the North Pacific, sounding out lines for a projected Pacific cable. Since that time investigation has been carried out by ships of all nations, on a scale too extensive for detailed record.

In 1902 at Stockholm was founded the International Council for the Study of the Sea, whose headquarters are in Copenhagen. The idea is to help and control the fisheries in the Baltic, the North sea, the Norway sea and Barents sea, as well as in British and Irish waters. Besides the northwestern European states Portugal, Spain and Italy have also become members of this union, which has done much to improve the instruments and methods of oceanography. Generally, each government has built or fitted out a research steamer for the work. The United States of America, Canada and Japan also take part.

Surface of the Ocean.—If the whole globe were covered with an ocean of uniform depth and at rest, the surface would form a perfect ellipsoid of revolution. But the water surface is broken by land, and the mean density of the substance of the land is 2.6 times as great as that of sea water, so that the gravitational attraction of the land must necessarily cause a deviation of the plumb line toward the continent. Hence, the geoid or figure of the ideal sea surface is not part of an ellipsoid of rotation but is somewhat irregular. Recent pendulum observations have shown great local differences in density in the earth's crust, a marked deficiency of mass under high mountains and excess under the bed of the ocean. The intensity of gravity at the surface of the sea far from land has been measured on several occasions and has been found to be normal. The inequalities of the geoid are not more than 100 m.

In the absence of other forces the sea surface would always coincide with the geoid, but distortions of the ocean surface arise from the effect of the tide-producing forces and from meteorological causes and may be periodic or unperiodic in their occurrence. Except for the tides, they do not amount to more than one or two metres. The atmosphere affects sea level by its varying pressure. Atmospheric precipitation poured into the sea by the great rivers must necessarily maintain a permanent rise of the sea level at their mouths, and from this cause the level around the coasts of rainy lands must be higher than in mid-ocean. The Baltic is fuller in the time of the summer rains than in winter, when the rivers and lakes are frozen and most of the precipitation on the land is snow. A similar range occurs on the Netherlands coast in the North sea, where the maximum level is reached in October, the month of highest rainfall, and there is a range of 200 mm. to the minimum level at the time of least rainfall in early spring. Heating and cooling of the surface layers are accompanied by expansion and contraction and also lead to rhythmic variation of sea level.

In the monsoon regions the half-yearly change from onshore to offshore winds produces noticeable differences in level, the total range being 237 mm. The influence of wind on water level is most remarkable in heavy storms on the flat coasts of the North sea and the Baltic, when the rise may amount to many feet. In the region of tropical storms the extreme winds may cause a heaping-up of water capable of devastating the low coral islands of the Pacific. The old speculations as to a great difference of level between the Mediterranean and the Red seas have been proved by precision levelling to be erroneous.

Deviations from the geoid amounting to more than one metre are also related to the presence of the permanent ocean currents as described below.

Land and Water.—The ocean waters are continuous around the antarctic, and the names Atlantic, Pacific and Indian oceans are applied to the three large "gulfs" that extend northward between the continents. Because of the topographic relationships the North Polar sea is considered as a part of the Atlantic ocean. Southern or Antarctic ocean is sometimes used to designate the waters of the southern latitudes extending from the antarctic to the subtropical convergence (about 40° S.).

Various systems have been proposed and used for designating subareas of the open ocean. Some of these are based on arbitrarily designated boundaries, others make use of the bottom topography and others are based on climate, currents and physical and biological criteria.

Examination of the globe shows that the proportion of water is much greater in the southern hemisphere than in the northern.

All oceans and seas	361.06×10^6km.^{2}	70.8%
All land.	148.89×10^6km.^{2}	29.2%
Northern hemisphere—Oceans and seas .	154.70×10^6km.^{2}	60.7%
—Land . . .	100.28×10^6km.^{2}	39.3%
Southern hemisphere—Oceans and seas .	206.36×10^6km.^{2}	80.9%
—Land . . .	48.61×10^6km.^{2}	19.1%

Relief of the Sea Floor is important for many reasons. It forms the lower and lateral boundaries of the ocean waters; its

elevations impede the free flow of water; it affects the distribution of sediments and is of interest to the geomorphologist and geologist. The development of echo-sounding devices (about 1925) greatly accelerated the study of submarine topography by providing a simple and rapid method of obtaining depth measurements.

The greatest depths occur in the Pacific ocean where soundings of about 10,500 m. have been obtained in the Philippine trench by the "Emden" and more than 10,000 m. in the Japan trench by the U.S.S. "Ramapo." The greatest depth in the Atlantic, 8,750 m., was obtained by the U.S.S. "Milwaukee" in the Puerto Rico trench. The great depths in the Pacific exceed the elevation of Mount Everest by about 1,500 m.

The relative distribution of elevation and depth can be shown by a hypsographic curve, showing two primary levels of reference, one slightly above sea level, the other at depths between 4,000 to 5,000 m. Elevations of more than 1,000 m. on land and depths greater than 6,000 m. represent only a small percentage of the earth's surface. Also, there is only a relatively small percentage of the sea bottom with depth between 200 and 3,000 m. The mean elevation of the land is 840 m. and the mean depth of the oceans is 3,800 m. The hypsographic curve should not be interpreted as an average profile of the land surface and sea bottom because the highest mountains are commonly near the coast line (*e.g.*, west coast of South America) and the greatest depths are found near the margins of the ocean and not in the middle of the oceanic depressions.

The continental shelf, with depths less than 200 m. to 400 m., is of variable width, ranging from about 750 mi. to the north of Norway and the U.S.S.R. to virtually zero off mountainous coasts. It averages about 30 mi. in width. Although the average slope of the shelf is small, detailed surveys reveal minor terraces, ridges, hills and depressions as well as steep-walled canyons, some of which are probably related to erosion and deposition during periods of lowered sea level. The inclination of the continental slope varies between about 2° and 3.5°, being least off low-lying land and steepest off mountainous coasts. Submerged slopes of volcanic islands are similar to the exposed portions and may be as great as 50°.

The *Carte Générale bathymétrique des océans dressée par ordre de S.A.S. le Prince Albert de Monaco,* first issued by Prince Albert of Monaco in 1904 and more recently by the International Hydrographic bureau at Monaco, is the standard representation of oceanic bottom topography. Periodic revisions are made, and the third edition was being issued when interrupted in 1939 by the outbreak of World War II. Smaller and less detailed charts of deep-water topography are published by various national hydrographic agencies.

With the great increase in bathymetric knowledge since 1930, agencies such as the Geological Society of America have sponsored the preparation of detailed charts of the continental shelves and slopes. These have brought to light a complex topography of which the most striking features are submarine canyons which cut into the slope and sometimes across the shelf. Off the Hudson, Congo and Indus rivers are canyons which bear some relation to the rivers. Others occur in areas where there are no large rivers. In general, they are V-shaped in profile, with bottoms sloping continuously outward. Some are winding and many are branched. The larger canyons are comparable in size and relief to the Grand Canyon of the Colorado river. The question as to the origin of these canyons is unsettled.

MARINE SEDIMENTS

Most of the sedimentary rocks on land were deposited under the sea. A study of the various marine environments of deposition, the associated marine organisms, texture, composition and colour of the sediments is therefore of interest beyond the realm of oceanography because only in the sea can be found the answers to many geological problems.

Sir John Murray is credited with the first intensive investigation of marine sediments, and the report on the "Challenger" material (Murray and A. Renard, 1891) set the pattern for many later investigations. The development of chemical and physical techniques has opened new fields of study; for example, X-ray spectroscopy has provided a means for identifying the fine-grained clays which were previously considered to be amorphous material.

Sources of Sedimentary Material.—The materials found on the sea floor can be grouped in six general classes, although the proportions of each may vary between wide limits:

1. *Terrigenous debris,* arising from mechanical disintegration and chemical decomposition of exposed rocks, is carried to the sea.

2. *Volcanic debris* is contributed by land volcanoes as well as those completely below the sea surface. Volcanic ash is carried for tremendous distances in the air and floating pumice is widely dispersed by currents.

3. *Remains of organisms,* principally the hard calcareous skeletal structures of plants and animals, make up a large proportion of many deep-sea sediments and also shallow-water deposits in tropical seas. Skeletal structures of silica are less abundant but are widely distributed. Both plant and animal remains are important. These organic remains correspond to the fossils in rocks.

4. *Inorganic precipitates* are never abundant but are sometimes conspicuous and diagnostically important. Examples are calcium carbonate (in a few areas), dolomite, iron and manganese oxides, phosphatic and barite nodules and, where H_2S is present, ferrous sulphide.

5. *Products of chemical transformation* are minerals formed by the interaction of sea water and rock particles. Examples are glauconite, phosphorite, feldspar, phillipsite and clay minerals.

6. *Extra-terrestrial materials* are extremely rare, but small magnetic spherules and small brown crystalline spherules occurring in red clay are believed to be of meteoritic origin.

Transportation of Sedimentary Material.—Material introduced to the sea by erosion, rivers, the air, or produced in the sea, may be carried for great distances before it reaches its last resting place. With the exception of ice and organic rafting, it is a general rule that small particles, or at least light material, will be carried the greatest distances from their point of origin.

Ice is important only in the higher latitudes. Glaciers carry a heavy load of unsorted rock debris and, when they calve, the resulting icebergs may carry boulders and pebbles as well as finer material thousands of miles before they melt and drop the last of their burden to the bottom. Sea ice near shore is often frozen solid to the bottom during winter. When it thaws on top it may break away and carry with it the frozen sediment which is dumped elsewhere as the thawing continues.

Organic rafting does not carry much material but, like the icebergs, rafts of land vegetation or large seaweeds may transport rocks and pebbles far from land.

Atmospheric transport of volcanic ash distributes this material all over the earth. In areas where strong offshore winds blow across arid regions, as off the west coast of Africa, aeolian debris forms an important constituent of the deep-sea sediments.

Currents carry material in several different ways. Slowly sinking particles will be carried along as they gradually fall toward the bottom. Near and on the bottom, material may be moved by mudflows, sliding, rolling and saltation, or may be carried in suspension. All these processes have their counterparts in the atmosphere in landslides, drifting sand and snow and in dust storms. There is little direct evidence of mudflows, but they are believed to be common in areas of steep slopes and rapid deposition. The eroding velocity required to move particles on the bottom is not well known, but it is believed that a flow of about ten centimetres per second will carry particles less than one millimetre in diameter.

Gross Properties of Marine Sediments.—The over-all characteristics of a sediment are colour, texture and composition. Marine sediments vary from white through gray to black, with additions of various amounts of yellow, red, blue or combinations of these colours. Light-coloured sediments are usually coarse-grained. Black sediments are typical of stagnant conditions. Near rivers the sediments are often reddish, and most shallow terrigenous deposits are green or olive-green. The deep-sea red

clay is reddish or brown in colour, and sediments high in skeletal materials are generally light-coloured. Texture covers a wide range, from boulders and cobbles to those sediments composed entirely of impalpable clay. Most samples contain a range in particle sizes and, except in areas of currents, are not well sorted. The composition is of course an index of the sources of the constituents of a sediment. Microscopic and chemical analyses are the direct ways of determining the composition.

Pelagic and Terrigenous Sediments.—Pelagic sediments are those found in deep water far from land. Materials containing less than 30% of organic remains are called red clay. The organic deposits are then divided into calcareous and siliceous oozes which contain more than 30% of organic remains. Calcareous oozes are: (1) globigerina ooze, in which pelagic foraminiferal remains are dominant; (2) pteropod ooze, containing conspicuous shells of pelagic molluscs; and (3) coccolith ooze, containing large numbers of skeletal fragments of Coccolithophoridae. Siliceous oozes are: (1) diatom ooze, containing principally diatom frustules; and (2) radiolarian ooze, containing abundant skeletons of radiolaria. Terrigenous sediments are variable in colour, texture and composition, but always contain some recognizable terrigenous debris. On the basis of texture they are designated as cobbles, gravel, sand, silt, mud, etc., or combinations of these terms. Some indication of composition or origin is indicated by such terms as calcareous, siliceous, coral, volcanic, glacial, etc., generally prefixed by an adjective describing the colour.

Distribution of Pelagic Sediments.—Red clay and globigerina ooze are the most abundant types. Diatom oozes are restricted to high latitudes, and radiolarian oozes are almost exclusively limited to the Pacific, whereas pteropod ooze is significant only in the Atlantic.

Composition of Pelagic Sediments.—There are three extreme types of pelagic sediments: those completely devoid of organic remains (that is, pure red clay), those entirely composed of calcareous remains and those made up of siliceous remains. Actually, most sediments can be considered as mixtures in varying proportions of the three extreme types, although sediments high in calcareous remains contain few siliceous skeletons, and vice versa. The great differences in texture, physical and chemical composition of the three extreme types are reflected in the properties of a sediment sample. Calcareous sediments usually contain some material larger than 0.1 mm., but broken and disintegrated shells may make up most of the sample. The red clays have a median diameter of about 0.001 mm. Diatoms and radiolarian remains are usually larger than 0.1 mm.

Chemical analyses of red clay (free from calcium carbonate) show that, compared to igneous rocks, it is higher in aluminum, iron and manganese, and lower in calcium, potassium and sodium. The higher proportion of iron and manganese is believed to be the result of deposition of their oxides in the sediments as concretions. Nodules containing these oxides are frequent constituents of red clay. The fine material is believed to originate on land and, to some extent, by the submarine weathering of volcanic material. The following clay minerals have been found in marine sediments: kaolinite, montmorillonite, hydrated halloysite and a muscovitelike clay. Many of these substances are capable of basic cation exchange.

Calcium Carbonate Deposition.—Most of the calcareous deposits are of organic origin, but in certain restricted shallow-water areas, such as in the Red sea and on the Bahama banks, direct chemical deposition occurs. Precipitation of calcium carbonate by organisms is favoured by warm temperatures and by the activity of plants which reduce the total CO_2 content of the water and thus increase the $CO_3^=$ ion concentration. In the open ocean the deposition of calcium carbonate is affected by (1) solution during settling to the bottom and (2) solution on the bottom. The concentration of calcareous debris will depend on these two factors and, in addition, upon the relative rate of accumulation of inorganic debris. Below 3,000 m. the calcium carbonate content decreases rapidly with depth. In the North Pacific the content is relatively low at all depths. The decrease with depth is believed to be the result of solution during sinking and on the bottom, and the anomalous condition in the North Pacific can probably be explained in terms of these factors. Calcareous remains behave as coarse particles and accumulate on topographic highs, whereas the fine-grained clays are swept into the depressions.

Organic matter forms a small but important constituent of the sediments. The decomposable organic debris settling to the bottom forms the source of food for benthic animals and bacteria; in turn, their activities alter the chemical environment on and in the sediment, and burial of organic debris removes from solution significant quantities of carbon, nitrogen and possibly other elements. Organic-matter content averages about 1% in pelagic sediments and 2.5% in nearshore deposits. High values are found in bays, estuaries, isolated basins, fjords and beneath stagnant waters such as the Black sea. In general, the organic-matter content decreases with depth in the sediment core because of bacterial decomposition. Organic material in fossil sediments is believed to be the source of petroleum.

Rates of sedimentation have been estimated by stratigraphic and supply methods. Core samples up to about three metres long taken in the open ocean of the Atlantic have revealed varying composition with depth. Based on the pelagic foraminiferal remains and on the presence of layers containing coarse terrigenous debris, supposedly ice-borne, it has been possible to establish the thickness of the layer deposited since the last glacial period. The average rates for globigerina ooze, red clay and a terrigenous blue mud are 1.2, 0.86 and 1.78 cm. per 1,000 years, respectively.

Other scattered data indicate rates of deposition of the order of 1.0 cm. per 1,000 years or less for pelagic deposits. Although highly variable, it is believed that nearshore deposits accumulate at an average rate of about 10 cm. per 1,000 years.

Factors Determining Character of Sediments.—The factors most important in determining the character of marine sediment are (1) general topography and depth of the site of deposition, (2) relation of site of deposition to sources of inorganic material, (3) physical and chemical conditions in the water column overlying the site of deposition. Topography is, in one sense, a measure of the action of water movements in transporting material, highs being swept clear of fine debris which finds its way into depressions. The various modes of transportation and proximity of sources of material must also be evaluated. The character of the physical and chemical conditions is the fundamental factor in estimating the contribution of calcareous and siliceous skeletal material and of organic matter.

CHEMISTRY OF SEA WATER

If suspended material of organic and inorganic origin is excluded, sea water is an aqueous solution of dissolved solids and gases. For the more abundant elements the early results of W. Dittmar (1884), based on the "Challenger" material, agree well with the best estimates based on analyses up to 1940.

The table contains a list of all elements known to be present as dissolved compounds excluding gaseous oxygen, nitrogen and the inert gases neon, helium and argon. A total of 49 elements are known from direct or indirect analyses.

Chlorine, present as chloride ion, is the most abundant element and accounts for about 55% of the dissolved solids. Six ions, chloride, sodium (30.6%), sulphate (7.7%), magnesium (3.7%), calcium (1.2%) and potassium (1.1%) together make up more than 99% of the dissolved solids. It will be noted that for the following elements ranges in concentration are indicated: silicon, nitrogen compounds, phosphorus compounds, arsenic, iron, manganese and copper. These are substances which are present in small amounts but which are essential to living organisms. Nitrate, phosphate and silicate are often called fertilizers or plant nutrients.

Dissolved Gases.—All the atmospheric gases are present in solution in sea water. In stagnant areas (no dissolved oxygen) hydrogen sulphide is found and methane may be present.

The solubility of oxygen and nitrogen decreases with increasing temperature and salinity. At saturation, the following values occur in water of $Cl = 19‰$.

	Oxygen, ml./l.	Nitrogen, ml./l.
0° C.	8.08	14.40
20° C.	5.38	9.65

Although the ratio of oxygen to nitrogen in the atmosphere is 1:3.7, in the sea water it is about 1:1.7 because of the greater solubility of oxygen.

Dissolved nitrogen gas is not affected by biological activity and is always present at about the saturation value determined by the temperature and salinity. At depths greater than a few hundred metres oxygen is generally below saturation because of its utilization. In large areas of the Pacific at mid-depths it is present in amounts less than 1 ml. per litre. In the euphotic zone (less than 100 m.) photosynthetic activity may increase the oxygen content over the saturation value.

*Elements Present in Solution in Sea Water**

*From H. U. Sverdrup, M. W. Johnson and R H Fleming, *The Oceans* (Prentice-Hall, Inc., 1942).

Carbon dioxide in sea water is chiefly present as carbonate and bicarbonate ions balanced against basic cations. It is present in the following forms, and for any given set of conditions an equilibrium prevails:

CO_2 (dissolved) $\rightleftarrows H_2CO_3 \rightleftarrows HCO_3^-$ (bicarbonate) $\rightleftarrows CO_3^=$ (carbonate). To remove all CO_2, a strong acid must be added to sea water. If CO_2 is removed, the equilibrium is shifted toward more carbonate ion; if CO_2 is added, the amounts of bicarbonate and then carbonic acid and dissolved CO_2 increase. In equilibrium with the atmosphere, the amount of free CO_2 and H_2CO_3 solution decreases with increasing temperature.

The *p*H or hydrogen ion concentration depends upon CO_2 content, temperature and salinity, and varies between about 7.5 and 8.4. The higher values occur near the surface and the lower values in water where the oxygen has been consumed and converted to CO_2 in respiration.

The alkalinity is a measure of the basic cations balanced against weak acids (carbonic and boric). It bears a relatively constant ratio to the chlorinity and is affected slightly by precipitation and solution of calcium carbonate.

The solubility of calcium carbonate is not definitely known. Apparently warm surface sea water is nearly saturated or slightly supersaturated, whereas the deeper waters are undersaturated where much oxygen has been consumed.

Effect of Rivers.—The composition of the dissolved salts in river water is variable and depends upon the amount of rainfall and type of rocks and soil which have been in contact with the water. F. W. Clarke (1924) has estimated that rivers each year add 2.73×10^9 metric tons of dissolved solids to the sea. Calcium carbonate is notably more abundant in river water, but in the sea there is a deposition by organisms which probably balances this tendency to increase the content of calcium. Estimates of the age of the ocean based on the present rate of supply of elements by rivers lead to values of about 100,000,000 years, a much shorter time than estimates made by other means.

Geochemistry of the Ocean Waters.—The total amount of dissolved salts in the sea is about 5×10^{16} metric tons. This would form a layer of salts 45 m. thick over the entire earth, or 153 m. thick over the present land area. It is estimated that about 600 g. of rock have been weathered for every kilogram of water in the oceans. Sulphur, chlorine, bromine and boron occur in amounts greater than were present in this amount of rock and were presumably present as volatile substances in the primeval atmosphere. Elements forming relatively soluble compounds, notably calcium, sodium, potassium, magnesium, carbon, strontium, selenium and iodine are present in amounts greater than 1% of the potential supply. Silicon, aluminum and iron which are abundant in rocks are present only as minor constituents in sea water because they do not form soluble compounds.

Composition of Marine Organisms.—Most of the elements listed in the table have been found in organisms, some of which also contain a few rare elements not yet reported directly from sea water. It is best to consider the composition of marine animals in three parts, organic material (soft tissues), skeletal structures and body fluids. The composition of carbohydrates, lipids and proteins are relatively uniform in elementary composition. Skeletal structures vary greatly, and the inorganic solutes in the body fluids are only slightly modified sea water. A comparison of the relative compositions of organisms and the dissolved material in sea water shows that the organisms "concentrate" nitrogen and phosphorus, and sometimes iron and silicon in their tissues and skeletons. Since these elements are scanty they can virtually be exhausted and, hence, produce desert conditions in the sea—barren of plant and animal life because of lack of fertilizers rather than of water.

It has been found that the ratios of carbon:nitrogen:phosphorus in marine organisms and in sea water are virtually constant, 41:7.2:1 by weight or 106:16:1 by atoms. Their depletion through photosynthetic activity and their regeneration during respiratory activity is parallel. Regions low in phosphorus are low in nitrogen and when the oxygen content is low the nutrients are abundant. The surface layers of the open ocean are deserts because of the virtual absence of phosphate and nitrogen compounds. Regions where deeper waters are brought to the surface by winter overturn, mixing or upwelling are the verdant jungles of the sea, teeming with microscopic plant life, zooplankton, fishes and marine birds (*see* MARINE BIOLOGY). In higher latitudes, low temperatures and lack of light limit photosynthesis during the winter and allow time for the regeneration of the nutrient elements. Estimates of total production can be made on the basis of the depletion of nutrients (*see* below).

Salinity and Chlorinity.—In 1902 an international commission established the relationships between salinity, chlorinity and the density of sea water. Salinity is a defined measure of the total dissolved solids (salt content) of the water. The chlorinity is an easily measured quantity obtained by titrating sea water with silver nitrate following a prescribed method. The two are related as

$$\text{Salinity} = 0.03 + 1.805 \times \text{chlorinity}.$$

Both terms are always expressed as grams per kilogram, that is, parts per thousand, for which the symbol ‰ is used.

In the titration with silver nitrate, bromides and iodides are precipitated with the chlorides but are computed as if they were chlorides. Hence, the chlorinity is greater than the chloride content. Because changing atomic weights slightly affect this relationship and because of the difficulty of preparing standard chloride

solution of sufficient accuracy, all oceanographic work is based on "normal water" (*eau de mer normale*) prepared under the auspices of an international commission.

The validity of the salinity: chlorinity relationship depends on the results of careful chemical analyses which have shown that, regardless of where the water is collected, the ratios between the abundant elements are virtually constant. Slight variations are known to occur in certain elements affected by biological activity, and in areas of high dilution the concept of constant composition is not valid because the ratios of dissolved salts in river water are variable and different from those in the sea.

Because of the constancy of composition, the density at a given temperature is related to the salinity and chlorinity; and if one of them is known, the others can be obtained from M. Knudsen's *Hydrographical Tables*. Salinity is rarely measured directly and the chlorinity titration is the standard method of determining the concentration of sea water. Density and certain other physical properties are also used. Density measurements are made with pycnometer bottles, by total immersion hydrometers, or floats. Electrical conductivity and refractive index methods have also been devised. Since density and the other properties depend on temperature, they are always standardized against chlorinity measurements on control samples.

Temperatures in the oceans range from about $-2°$ C. to more than $30°$ C. The lowest value is limited by the freezing point of sea water, and the upper limit by processes of radiation and exchange of heat with the atmosphere. Temperatures higher than $30°$ C. may occur in land-locked tropical seas such as the Red sea and the Persian gulf. The range in salinity is generally between $33^0/_{00}$ and $37^0/_{00}$. The surface salinity in high latitudes, in regions of heavy rainfall and off large rivers, may be much lower, and in certain semienclosed areas, such as the Gulf of Bothnia, may approach zero. In isolated seas in intermediate latitudes, such as the Red sea, the salinity may exceed $40^0/_{00}$.

A representative salinity of $35^0/_{00}$ or a chlorinity of $19^0/_{00}$ ($S=34.325^0/_{00}$) is often used in discussions of the composition of sea water.

Pressure.—Hydrostatic pressure is expressed in atmospheres or units of the centimetre-gram-second system. An atmosphere is equal to 1.0133×10^6 dynes/cm². One million dynes per square centimetre was designated as 1 bar by V. Bjerknes. The unit in common use in oceanography is the decibar, one-tenth of a bar. One atmosphere corresponds to approximately ten metres of water; therefore, depths in metres and pressures in decibars are expressed by nearly the same numerical value.

Pressures range from zero at the surface, neglecting atmospheric pressure, to more than 1,000 atmospheres (about 15,000 lb. per square inch) or 10,000 decibars in the deepest parts of the ocean.

Density of Sea Water.—Density is the mass per unit volume and is usually reported as grams per cubic centimetre. The density of sea water depends upon its temperature, salinity and the hydrostatic pressure. Density is represented by the symbol $\rho_{s,t,p}$, the subscripts indicating the three variables. Since the density of sea water is in the range 1.000 to 1.040, it is common practice to report σ_t values where

$$\sigma_t=(\rho_{s,t,p}-1)\ 1{,}000.$$

If the water is at $0°$ C. and atmospheric pressure, the direct relationship between density, salinity and chlorinity is given by M. Knudsen's *Hydrographical Tables*. At any other temperature the correction for the thermal expansion can be obtained from the same source. The compressibility correction necessary for computing the density *in situ* was derived by Bjerknes and J. W. Sandström.

In oceanographic work the specific volume (α) is often used instead of the density. Because the range in values is small it is convenient to employ specific volume *anomalies* which are indicated as δ where

$$\delta=\alpha_{s,t,p}-\alpha_{35,0,p},$$

the value of $\alpha_{35,0,p}$ being that of water of salinity $35.0^0/_{00}$, temperature of $0°$ C. at the indicated pressure, p, expressed in decibars. Tables for obtaining δ are given by H. U. Sverdrup, M. W. Johnson and R. H. Fleming.

PHYSICAL PROPERTIES OF SEA WATER

The properties of pure water are dependent upon temperature and pressure; those of sea water are also affected by the salinity. Details concerning the physical properties can be found in the International Critical Tables and are stated by N. E. Dorsey, and by Sverdrup *et al.* Earlier compilations are given by O. Krümmel.

Heavy water (deuterium oxide) is present in sea water in amounts greater than in fresh water or rain water. The ratio of hydrogen to deuterium is about 7,000: 1.

Thermal expansion increases with temperature, pressure and salinity.

Thermal conductivity is essentially the same as for pure water. The molecular transfer of heat, however, is rarely a significant process in the sea, where the state of motion results in eddy conductivity which is many times greater.

Specific heat at constant pressure decreases slightly with increasing salinity, temperature and pressure.

Latent heat, the amount of heat required to produce one gram of water vapour at the same temperature as the water, decreases with increasing temperature. Between $0°$ and $30°$ C., latent heat in calories $=596-0.52\times t°$ C.

Adiabatic temperature changes must be taken into account in studying the temperature distribution in the deep basins. Compression results in heating, expansion or pressure release in cooling. Although the effect is small, water raised from 10,000 m. will cool more than $1°$ C. when brought to the surface. The adiabatic gradient is approximately $0.1°$ C. per 1,000 m.

Colligative properties, vapour-pressure lowering, freezing-point depression and osmotic pressure depend upon the salinity. The effects of temperature on all of these properties is believed to follow the usual relationships for solutions.

Maximum density of pure water is at nearly $4°$ C. For sea water the temperature of maximum density decreases with increasing salinity. For salinities greater than about $25^0/_{00}$ the temperature of maximum density is below the freezing point; hence, the water continues to cool and mix until freezing occurs at the surface.

Compressibility must be known to compute density *in situ.* It decreases with increasing temperature, salinity and pressure.

Viscosity and diffusion, like thermal conductivity, have little effect on the transfer of momentum and of chemical properties because of the dominant role of turbulent transfer. Eddy coefficients much greater than the laboratory values, but highly variable, are found in the sea.

Surface tension decreases with increasing temperature and increases slightly with salinity. Organic substances in solution often reduce the values below those for "pure" sea water.

Refractive index has been used as an indirect method for measuring the salinity. It increases with salinity and decreases with increasing temperature.

Electrical conductivity has also been used for an indirect method of determining salinity. The conductivity increases with salinity and temperature.

Velocity of sound in sea water increases with increasing temperature, salinity and pressure, with extreme range of values between about 1,450 and 1,550 m. per second. Water is a good conductor of sound, absorption losses being negligible except at supersonic frequencies. Echo-sounding systems are based on timing the interval required for a sound impulse to travel from the ship to the sea bottom and for the echo to return to the ship. Horizontal transmission of sound is used in surveying work (radioacoustic-ranging).

Absorption of radiation (transparency and colour). The penetration of light in the sea is important not only in heating the water but also to the photosynthetic activity of plants and to the vision of animals. Pure water is most transparent to radiation in the blue and green portions of the spectrum; thus, sunlight transmitted through clear water appears blue. Studies of sea water indicate values approaching those of pure water but in many areas,

particularly near shore, the transparency is much reduced and there is a shift in the colour of the transmitted light toward the green and yellow.

The reduced transparency in the sea is believed to be caused by minute particles of dust and organic debris that scatter the light. In coastal waters organic debris and a dissolved yellow substance, probably of organic origin, contribute greatly to the reduced transparency.

Water is virtually opaque to ultra-violet and infra-red radiation. Approximately 50% of the sun's radiation is in the long-wave, infra-red region and is absorbed in the first few centimetres of water.

The transparency of sea water has been studied by means of the Secchi disk, by spectrophotometers and by photoelectric cells with filters which are lowered in the sea. Photographic plates exposed at depths as great as 1,000 m. have shown some fogging, but the amount of light present below 500 m. in clear tropical latitudes is probably inadequate for vision. In coastal waters this limit of visibility may be as shallow as 50 m.

The colour of the sea ranges from a deep blue in areas of clear water such as the Sargasso sea and the Mediterranean to blue-green and green, and a greenish-brown near shore. The colour of the water is usually recorded on the "Forel scale," which is an arbitrary series of colours ranging from blue to yellow. The blue colour is attributed to the scattering of light by extremely minute particles and possibly by molecules so that it is comparable in origin to the blue of the sky. Near shore the green and yellow are associated with plankton, organic and inorganic debris and yellow pigment. The sea surface is sometimes discoloured by concentrations of debris or living organisms. "Red water" is common in certain areas where tremendous concentrations of algae or dinoflagellates occur. The Red sea and the Vermilion sea (Gulf of California) are named for such phenomena.

ICE IN THE OCEAN

Ice in the ocean occurs as icebergs or as sea ice. Icebergs are formed by the "calving" of glaciers and consist therefore of pure ice. Sea ice is ice that forms when sea water freezes and generally contains salt. There is an elaborate terminology to describe icebergs and sea ice.

When sea water is cooled to its freezing point, which lies below that of fresh water, elongated crystals of pure ice are first formed. These grow rapidly into a matrix in which sea water becomes trapped in amounts which depend upon the rate of freezing. Sea ice therefore consists of pure ice full of small cells that contain brine. When the temperature of the ice decreases, the cells decrease in size and the brine becomes more concentrated. On the other hand, when the temperature of the ice rises, the cells increase in size and the brine becomes diluted. When the temperature of the ice approaches the freezing point of pure ice (0° C.), the ice becomes honeycombed and the brine trickles down, leaving the upper layers free from salt. Thus, at the end of the summer the tops of hummocked arctic ice consist of pure ice which on melting renders potable water.

The physical properties of sea ice depend upon the salt content of the ice and upon the presence of air bubbles.

OCEANOGRAPHIC METHODS

Oceanographic studies fall into two general groups, those observations which must be made *in situ,* and those that can be made on collected samples which, once obtained, can be examined at a later time either on shipboard or in the laboratory. In the first group of observations are soundings, observations of water movements (currents, waves and tides), temperature, transparency and certain other physical properties. In the second group are studies of the chemical and physical properties of the water, examination of biological collections and marine sediments, which are nearly always based on a laboratory examination of the samples. Rather specialized devices are necessary for making observations and collecting samples from below the sea surface.

Soundings in deep water are obtained by paying out a single or multistrand wire with a weight attached to the end. When the weight strikes the bottom, the tension on the wire is reduced and the amount of wire paid out is read off on a "metre-wheel." Depths greater than 10,000 m. have been measured in this way. The introduction of sonic-sounding (echo-sounding) devices has simplified this phase of the investigations.

Subsurface temperatures are usually measured by means of reversing thermometers, first developed about 1878. These are special mercury-in-glass instruments enclosed in a heavy glass sheath to protect them from pressure. These devices will measure temperatures with an accuracy of ±0.02° C. and can be used to the greatest depths. They are usually attached to the water-sampling bottles and lowered on a heavier wire rope than that used for sounding. Reversing thermometers, although extremely accurate, do not provide detailed information on the vertical distribution of temperature. To obtain such information continuous temperature recorders, such as the bathythermograph, have been devised, which can be lowered from a vessel under way and which record temperature against depth in the upper 300 m.

Water samples for salinity determination and for physical and chemical examination are obtained by special metal "bottles" which usually have the thermometers attached to them. One or more of these bottles are attached to the wire rope and lowered while open. At the required depth a messenger is dropped down the wire which activates a mechanism closing the first bottle and releasing another messenger which closes the second bottle, and so on. When all bottles have closed, they are raised to the surface and emptied into special glass bottles for later study.

Bottom samples are collected by means of snappers, coring tubes and dredges, and for work in deep water these are usually massive and require heavy gear for lowering and raising them. Snapper samplers are built like clam shells and scoop up a sample of the superficial layers of the sediment. Coring tubes are driven into the sediment by heavy weights or by an explosive charge which is detonated when the device strikes the bottom. Cores up to about 10 m. in length have been collected in depths as great as 4,000 m. Snappers and coring tubes can be used only in sand and soft sediments. To collect samples of rock it is necessary to use drag buckets or strengthened types of dredges similar to those used in biological collecting. Methods used to collect plants and animals are described elsewhere (*see* MARINE BIOLOGY).

TEMPERATURE AND SALINITY

Heating, Cooling and Evaporation.—The surface layers of the oceans receive heat by absorption of radiation from the sun and the sky and lose heat by back radiation, by conduction to the atmosphere and by evaporation. Heat is also transported into or out of any region by currents. The temperature in a given area depends, therefore, in a complicated manner upon the season, the circulation of the atmosphere and the currents. Although a small amount of heat is conducted through the ocean bottom from the interior of the earth, its effect on temperature distribution is masked by features related to the circulation of the water.

Evaporation takes place when the vapour pressure at the sea surface is greater than that in the air, and this condition always exists when the sea surface is warmer than the air. The greatest contrasts between air and sea temperatures are found in winter off the eastern coasts of the Asiatic and North American continents when cold polar continental air flows out over the warm waters of the two mighty currents, the Kuroshio and the Gulf stream. Therefore, by far the largest evaporation takes place off the eastern coasts in winter. Simultaneously, the air is heated and will arrive on the west coasts of the continents as moist and warm air. The oceans function as a huge system of circulating warm water; the surface layers are heated in summer, and the warm waters are carried north along the east coasts of the continents where in winter they give off part of their heat content to the air and supply the atmosphere with moisture.

Temperature and Salinity of the Sea Surface.—Merchant ships of different nations have collected from the oceans so many observations of sea-surface temperatures that it has been possible to prepare charts showing the average annual temperature of the sea surface as well as mean monthly temperatures.

Over the large tropical areas of the oceans the average sea-surface temperature is above 25° C., exceeding 27° in the Atlantic ocean and 28° in the Pacific and Indian oceans. According to Otto Krümmel, the percentage areas of the different oceans of high surface temperature are as follows:

Percentage of Ocean Surface

With temperature	Atlantic	Indian	Pacific
Above 77° F. (25° C.)	22.4	38.0	40.1
Above 68° F. (20° C.)	50.1	51.7	58.4

In the Atlantic and Pacific oceans these warm areas are narrow in the eastern parts of the seas and wide in the western parts, but in the Indian ocean this feature is reversed. To the north and south of the warm region the sea-surface temperature decreases and the isotherms tend to run east-west. There are many exceptions to this rule, however, particularly in the eastern parts of the Atlantic and Pacific oceans where the currents exercise a great influence upon the course of the isotherms.

The annual variation of the sea-surface temperature is small in the tropics where the annual range is only 1°–2° C. In the southern oceans the annual range reaches a maximum of 5°–6° C. in about lat. 35° S. and decreases again to about 2° C. in the antarctic water. In the North Pacific and the North Atlantic oceans the average annual range reaches about 9° C. in lat. 40° N. and decreases to a small value when approaching the arctic. In the northern oceans the east-west variation in annual range is more conspicuous than the north-south. Thus, in lat. 40° N. the annual range of surface temperature is about 17° C. on the east coast of Japan as compared with 4° C. on the American west coast. This and similar contrasts are related to the character of ocean currents.

The diurnal range of the sea-surface temperature is small throughout. In the tropics the range is from 0.2° to 0.3° C. and in middle latitudes in summer it is about 0.4° C. The range depends upon the altitude of the sun at noon, the cloud cover and the wind velocity. It increases with increasing noon altitude of the sun and decreases with increasing cloudiness and wind.

The salinity of the surface water is less well known because the determination of the salinity is more difficult than the measurement of the sea-surface temperature. Most of the available data are obtained from analysis of water samples collected by merchant ships. They are sufficient for the construction of charts showing average salinity but the seasonal variation in salinity can be examined in limited areas only.

In each of the oceans the average sea-surface salinity in any latitude is, according to Georg Wüst, equal to a basic value plus a term which depends upon the difference between evaporation and precipitation:

$$S=S_0+k(E-P)$$

where S is the average surface salinity, S_0 the basic value, E the evaporation (in centimetres), P, precipitation (in centimetres) and k is a constant. The constant k is the same for all oceans, but the basic salinity value differs from ocean to ocean. For the southern oceans, the South Atlantic and the South Pacific, the values are similar, 34.50‰ (parts per thousand) and 34.64‰, respectively, but for the North Atlantic the basic value is 35.30‰ and for the North Pacific it is 33.7‰. The Indian ocean has not been examined. The higher value for the Atlantic is probably related to the outflow of high-salinity water from the Mediterranean.

According to the above formula, a high surface salinity is found where evaporation greatly exceeds precipitation, and a low surface salinity is encountered where precipitation exceeds evaporation. Thus, belts of maximum salinity are found in both hemispheres in latitudes 20° to 25° where precipitation is small. The extremes are about 37.5‰ in the North Atlantic, 37.0‰ in the South Atlantic, 35.5‰ in the North Pacific and 36.5‰ in the South Pacific and Indian oceans. The belts are separated from each other by an equatorial region of lower salinity, 34.0 to 35.0‰, corresponding to the equatorial rain belt, and poleward salinities lower than 34.0‰ are found, corresponding to decreased evaporation and increased precipitation.

Only the major features of the salinity distribution are governed by this simple relationship. Details are related to the currents and, near land, are influenced by outflow of river water. In enclosed seas into which rivers empty, like the Black sea or the Baltic, low surface salinities are found, but in arid regions the salinity of an enclosed sea may be high. Thus, in the Red sea the salinity may exceed 41‰.

In the open ocean the seasonal variation of salinity appears to be small, but in coastal areas large variations occur associated with changes in discharge of river water and changes in currents.

Subsurface Temperature and Salinity.—Processes of mixing tend to produce a surface layer of nearly uniform temperature and salinity. In the tropics the intensity of mixing is nearly the same throughout the year, but in higher latitudes it is much more intense in winter than in summer. In winter it reaches to a depth of 100 to 300 m., and serves to return plant nutrients, phosphates and nitrates to the upper layers. Below the depth to which the winter mixing reaches, there is generally a layer, within which the temperature decreases rapidly with depth, which is called the main thermocline. This layer is not horizontal but is inclined, depending upon the currents. In the northern hemisphere it drops to the right relative to an observer with his back to the current. In summer the mixing penetrates to shallower depths only, depending upon the force of the prevailing wind and other factors. Below the depth to which the summer mixing reaches, is found a seasonal thermocline which in any given locality varies greatly in sharpness and depth.

Below the main thermocline, or roughly below a depth of 300 m., the temperature and salinity in any locality remain constant throughout the year except for such fluctuations as are related to fluctuations in currents. Temperature and salinity vary both horizontally and vertically, however, and these variations are closely related to the character of the oceanic circulation, as described later on.

In an examination of subsurface temperatures and salinities two useful tools have been introduced. B. Helland-Hansen showed that, when in a given region the temperature is plotted against the salinity, the observed values fall on a curve which defines a characteristic temperature-salinity relationship. On the basis of an analysis of such temperature-salinity relationships it has been possible to show that within each ocean characteristic water masses exist comparable to the air masses, which are discussed when dealing with the atmosphere. These relationships have been useful in studying the origin, depths of spreading and modifications of the water masses.

In each ocean there exist water masses which appear embedded between waters of different characteristics and which, with increasing distance from their region of origin, become mixed with the surrounding waters and lose their identity. Thus, the water which flows out from the Mediterranean along the bottom of the Straits of Gibraltar has a high salinity, and between latitudes 50° N. and 40° S. can be traced over the entire eastern North and South Atlantic by means of a salinity maximum at depths varying from 1,000 to 2,000 m. Similarly, low-salinity water sinks in the Antarctic in about lat. 50° S. and spreads to the north, where in the Atlantic ocean it can be traced to 20° N., and in the Indian and Pacific oceans to about 10° S. For tracing the spreading of such special masses, Wüst developed "the core method," the principle of which is to follow maxima or minima of temperature and salinity which are found near the centre, or core, of the water mass. The two methods, together with an examination of the oxygen content, have greatly clarified our concepts of the deep-water circulation of the oceans.

Basins.—Large bodies of ocean water, such as the waters of the Mediterranean, the Black sea, and the Red sea, are enclosed in basins which are in communication with the open oceans through narrow and shallow straits. In other instances the openings to the open ocean may be wide and fairly deep, but the sill depth in the openings may still be small compared with the depths on either side. Examples of such basins are found in the Caribbean sea, the Gulf of Mexico and between the islands of the East Indian archipelago.

Basins can be divided into two types, depending upon the man-

ner in which exchange of water with the ocean takes place. In one type, water flows in along the surface of the openings and out along the bottom, and in the other type the outflow takes place at the surface and the inflow along the bottom. In all cases the water in the basin will be uniform, but in the first type the basin water is formed by sinking of surface water in the basin itself, and its character depends upon the particular climatological conditions of the region. This, for instance, is the case in the Mediterranean and in the Red sea, where basin waters have a high salinity and a temperature corresponding to the lowest winter temperature in the area, in the Mediterranean a salinity of 38.6‰ and a temperature slightly above 13°, in the Red sea a salinity of about 40‰ and a temperature of about 20°. In the other type, the basin water has the character of the oceanic water that flows in over the sill, but the exchange is often so slow that the water in the basin is practically stagnant. This is the case in the Black sea where water diluted by run-off flows out along the surface of the Bosporus and where Mediterranean water flows in along the bottom, mixes with the outflowing water and reaches the Black sea with a salinity of about 22‰ and a temperature of 8°–9° C. In the Black sea this water is stagnant so that instead of containing oxygen it contains large quantities of hydrogen sulphide. Similar basin conditions are found in a number of fjords.

Where many wide openings exist, the surface water often flows freely through several openings, and the character of the water in the basin is determined by that of the oceanic water at the greatest sill depth. In these instances the renewal of the basin water is more rapid, and stagnating conditions are not encountered. In several of these basins the salinity of the basin water is uniform, but the temperature increases toward the bottom, corresponding to the effect of adiabatic processes. Thus, in the Mindanao trench the salinity below a depth of 3,500 m. remains constant at 34.67‰, but the temperature increases from 1.58° at 3,500 m. to 2.48° at 10,000 m., corresponding nearly to the increase which would result if water of a temperature of 1.58° were lowered adiabatically from a depth of 3,500 m. (a pressure of about 350 atmospheres) to a depth of 10,000 m. (a pressure of about 1,000 atmospheres).

OCEAN CURRENTS

Relation between Currents and Distribution of Temperature and Salinity.—The existence of large-scale permanent ocean currents is related to the fact that the sea surface is not flat but in many areas is inclined relative to the true horizon. Where the sea surface is inclined, the water tends to run downhill; but the effect of the earth's rotation enters so that the current runs, instead, parallel to the height contours of the sloping sea surface. It is well known that the wind does not blow from regions of high pressure to regions of low pressure, but that in the northern hemisphere, an observer with his back to the wind has the high pressure on his right and the low pressure on his left. This experience is explained by stating that the wind blows in such a manner that the pressure gradient is balanced by the deflecting force of the earth's rotation (the Coriolis force) which is directed at right angles to the motion, in the northern hemisphere to the right and in the southern hemisphere to the left. Similarly, an observer facing in the direction in which a current flows has, in the northern hemisphere, the sea surface rising on his right and dropping on his left, and the component of gravity acting along the sloping sea surface is balanced by the Coriolis force. The slope of the sea surface, however, is small. Off Cape Hatteras, where the Gulf stream flows toward the northeast with a speed of up to 3 knots, the sea surface rises to the southeast with a slope of 1.5:100,000. That is, it rises about 1 ft. in 11 nautical miles.

Observations show that the permanent currents extend to depths of several hundred metres, but their speed decreases with depth. The existence of these currents demonstrates that the gentle slopes of the sea surface are also permanent features which are related to the distribution of density. At great depths the density of the water is nearly uniform and, since the currents are weak, the pressure is nearly constant in any level surface. The heights of the water columns which exert this constant pressure depend, however, on the average density of the water. Where the average density is low, the water column is long; and where it is high, the water column is short. Consequently, the free surface of the sea must slope down from regions of low density to regions of high density or, since low density is generally equivalent to high temperature and high density is equivalent to low temperature, it can also be stated that the sea surface slopes down from warm regions to cold regions. Since a current flows along the contour lines of the sloping sea surface, one has the simple rule that a current flows in such a direction that in the northern hemisphere the warm water is on the right and the cold on the left of an observer looking downstream. Where a deep mixed layer exists, the rule indicates that the depth of the main thermocline increases to the right.

With this rule in mind, the general relationship between temperature distribution and currents is readily recognized. Thus, the Gulf stream off the North American east coast has the warm waters of the Sargasso sea on the right and the cold coastal waters on the left. The branch of the Gulf stream that flows along the west coast of Norway has the warm waters on the right, the coastal side, and the cold waters of the Norwegian sea on the left, and the south-flowing California current has the cold waters on the left, in this case on the coastal side.

Computation of Ocean Currents.—Ships' observations have rendered information as to the surface currents, and charts of surface currents have been prepared by the hydrographic offices of different nations. Few direct observations of subsurface currents are available, and our knowledge of these is mainly based on computations, using the above stated relationship between the distribution of density and the currents. Numerous deep-sea observations of temperature and salinity have been made from which the density at different depths can be found. Knowing the density, it is possible to compute the slope of the ocean surface, and of any other surface of constant pressure, relative to the slope of a selected pressure surface. Using the rule that when steady conditions exist, the component of gravity acting along a sloping pressure surface must be balanced by the Coriolis force, the currents can be computed relative to the unknown current at the selected standard surface. If it can be shown that at this surface the currents are weak, the computation renders the true currents.

This method was first proposed by H. Mohn and was later further developed by B. Helland-Hansen on the basis of the investigations by V. Bjerknes. The computations are now carried out by means of convenient tables and have given a fairly complete picture of the currents above a depth of about 1,000 m. At greater depths the currents are so weak that conclusions as to the direction of flow have to be based upon special features of the distribution of temperature and salinity.

Ocean Currents and Winds.—The relation between the ocean currents and the distribution of temperature and salinity has been described above, but nothing has been stated as to the manner in which the currents are maintained. Turning to that question we find that the oceanic circulation can conveniently be considered as composed of two systems: (1) a system of fairly rapid currents which are mainly confined to the upper 1,000 m. or less and are maintained by the prevailing winds, and (2) a system of slow and sluggish currents which reach to the ocean bottom and are caused by sinking of water that, in the enclosed seas of lower latitudes, has attained a high density by evaporation, and in high latitudes by cooling or by freezing of ice.

The prevailing winds exercise a twofold influence upon the ocean circulation. In the first place they maintain shallow wind currents, and in the second place they maintain the distribution of density to which the major currents are related. The nature of a pure wind current was first examined by V. W. Ekman, following a suggestion by F. Nansen, and was later studied by C. G. Rossby. Their theories have been developed on the assumption that the Coriolis force associated with the motion is at each depth balanced by a frictional force. The theoretical conclusion is that at the sea surface the current is directed about 45° from the wind, to the right in the northern hemisphere and to the left in the southern. With increasing depth the direction of the current turns right

(left) and the velocity decreases until at a depth of 50–100 m. the direction is opposite to that at the surface and the velocity is only a small fraction of the surface velocity. These conclusions have in the main been substantiated by observations.

The net transport of water by a pure wind current is directed at right angles to the wind, to the right in the northern and to the left in the southern hemispheres. This transport leads to the secondary effect of the permanent winds. Wind currents produced by the semipermanent anticyclonic winds of the subtropics will tend to transport the warm surface waters toward the centre of the anticyclone. Thus, they maintain an accumulation of warm water in the central region of high atmospheric pressure and as a result the sea surface slopes down in all directions from that region. This feature can exist as a permanent feature only in the presence of ocean currents which roughly run in the direction of the prevailing winds. Similarly, where the wind blows along a coast, with the coast on the right-hand side, the pure wind current will push the warm surface waters against the coast and a current must result running parallel to the coast in the direction of the wind. Where the coast is to the left, the warm surface waters are pushed out to sea and are replaced on the coast by cold water which rises from depths of a few hundred metres. This process, which is known as upwelling, occurs characteristically on the coast of California (spring and summer), Peru and northwest and southwest Africa (all year), as well as in other localities during limited periods. In these cases cold water is present along the coast and again a permanent current develops running parallel to the coast and in the direction of the wind.

From the preceding it follows that the permanent ocean currents are maintained by the prevailing winds and tend to flow in the direction of the wind. The currents therefore reflect the circulation of the atmosphere but with such modifications as arise from the effects of the coast lines. The broad equatorial currents flowing to the west are maintained by the steady trade winds. According to the rules which were stated, the depth of the main thermocline must, in the trade wind regions, increase with increasing distance from the equator and, consequently, near the equator water of relatively low temperature must be found at shallow depths. The presence of this water is related to the direction of the currents and is not an evidence of ascending motion, as is often stated.

On reaching the eastern shore of the continents the waters of the equatorial currents must bend north or south. The swift, narrow and warm currents along these shores, the Gulf stream, the Kuroshio, the Brazil current and the Agulhas stream (off southeast Africa) are therefore not maintained by the local winds but by the trade winds. When these currents turn seaward in middle latitudes, the bulk of the waters is soon deflected equatorward and the currents off the western coasts of the continent are broad, weak and cold (the Canary current, the California current, the Peru (Humboldt) current and the Benguela current). Where the coast lines permit circulation in higher latitudes, the contrast between eastern and western coasts is reversed. Thus, in the Norwegian sea the cold East Greenland current flows south off the coast of Greenland whereas a warm branch of the Gulf stream system flows north off the west coast of Norway.

The equatorial counter currents, which, in the calm belts, flow to the east as swift and narrow currents embedded between the equatorial currents, are also maintained by the winds but in a more complicated manner. The drag of the trade winds blowing to the west is not completely compensated for by the transport related to wind currents, but the drag also pulls the warm surface waters toward the eastern coasts of the continents. Consequently, sea level is a little higher off the eastern than off the western coasts, the difference in elevation being about 14 cm. in the Atlantic and about 60 cm. in the Pacific ocean, according to oceanographic observations. The equatorial currents, therefore, flow slightly uphill. In the belt of calms or variable winds between the two trade-wind regions there is no drag toward the west which can maintain the up-slope. There the water flows down the sloping surface toward the east, the calm belt lying so close to the equator that the effect of the earth's rotation in deflecting the currents is small. In the Atlantic and Pacific oceans the counter currents are found in 5°–10° N. and vary in intensity with the seasons, but in the Indian ocean the corresponding current is found in 5°–10° S. only during the season of the northwest monsoon which reaches peak intensity in February–March.

Deep-Water Circulation of the Oceans.—The ocean waters are in stable stratification; that is, the density increases with depth and the deep basins of the oceans are filled by water of a density greater than that at the surface. The difference in density between surface and deep water is particularly conspicuous in the tropics where the surface waters are relatively light because of their high temperature. Wherever the density of surface water is increased by cooling or evaporation so that it becomes greater than that of the surroundings, the water sinks and spreads horizontally when it reaches a layer of the density which it had upon leaving the surface. When surface water sinks, it is replaced by water which rises from some greater depth, and this process is called convection. The depth to which convection extends depends upon the manner in which density increases with depth.

In the tropics, cooling never takes place, and evaporation is not intense enough to increase the salinity to such an extent that water of high density is formed in the open sea. The convection processes in the tropics are therefore limited to a shallow surface layer. In middle latitudes the convection reaches deeper in winter, but only in such enclosed seas as the Mediterranean and the Red sea, where evaporation is great, do they penetrate to great depths. In high latitudes, on the other hand, where excessive winter cooling takes place, the convection processes may reach to the bottom of the ocean.

In the North Atlantic, regions of deep convection are found between Iceland and Greenland and in the Labrador sea, where the North Atlantic water, of a salinity close to 35‰, is cooled during the winter. When this water is cooled to between 2.5°–3° C., it attains the same density as the bottom water, and convection can reach from the surface to the greatest depth. On an average for the whole year, about 4,000,000 tons sink every second and spread as a slow deep-water current toward the south. In sections showing vertical distributions of temperature, salinity and oxygen content, this water can be traced by its high salinity, about 34.9‰, its temperature of about 3° C. and its high oxygen content. It fills all the deep basins of the North Atlantic and continues into the South Atlantic at depths between 2,500 and 3,500 m. as far south as lat. 40° S., where it gradually loses its identity because of mixing with water of antarctic origin. In the upper layers of this water mass the temperature and salinity are increased by addition of water from the Mediterranean. The Mediterranean has the character of a large evaporation basin which, below the sill depth of the Strait of Gibraltar, is filled by water of a uniform temperature of about 13° and a salinity of about 38.6‰. This warm and saline water flows out along the bottom of the Strait of Gibraltar, sinks, spreads and mixes with other water masses over large parts of the North Atlantic at depths between 1,000 and 2,000 m. Some water of Mediterranean origin is carried into the South Atlantic, where it can be traced to the latitude of the Cape of Good Hope. The high salinities and high temperatures at moderate depths in the North Atlantic were previously taken as evidence that high-salinity water was sinking in about lat. 30° N., but this concept can not be upheld.

Sinking of surface waters also takes place around the Antarctic continent. There the salinity of the surface water is generally low, but on the shelf surrounding the continent the salinity is greatly increased in winter by the freezing of ice, and water of a temperature of −1.9° C. and a salinity of 34.6‰ is formed and sinks. During sinking it becomes slightly mixed with water of somewhat higher temperature and salinity and reaches the bottom with a temperature of −0.4° C. and a salinity of 34.65‰. Thus, this water has a lower salinity than the bottom water of the North Atlantic, but it has also a lower temperature and is therefore slightly denser. It spreads toward the north, and in the Atlantic ocean it can be traced to about 10° N. lat.

Characteristic of the Antarctic is also a convergence of the

surface currents, which can be followed all around the continent between latitudes 50° and 60° S. Surface water of salinity 33.8‰ sinks at this convergence and spreads to the north at depths between 600 m. and 1,000 m. Although the salinity of this Antarctic intermediate water increases by mixing as the water spreads toward the north, a salinity minimum can be traced to 30° N. lat. Part of the intermediate water mixes with the underlying water of North Atlantic origin and is carried back again to high southerly latitudes where it rises toward the surface.

The deep-water circulation of the Indian ocean is simpler because the only major source of deep water is found in the south. The Antarctic bottom water and the Antarctic intermediate water can both be recognized, and between them is found a large water mass which contains components of North Atlantic and Antarctic origins. This water moves to the south at depths between 2,000 m. and 3,000 m. and rises to the surface in the Antarctic.

In the northern part of the Indian ocean, conditions are complicated by the spreading of high-salinity water which flows out from the Red sea along the bottom of the Strait of Bab-el-Mandeb. The amount of Red sea water which enters the Indian ocean, however, is much smaller than the amount of Mediterranean water flowing into the Atlantic and the effect upon distribution of temperature and salinity is correspondingly less.

In the North Pacific ocean no region is found comparable to the regions in the North Atlantic where bottom water is formed. To the north of lat. 45° N. the salinity of the surface waters of the Pacific is generally so low, less than 32‰, that, in spite of winter cooling, the density of the surface water never increases enough to develop deep convection. An appreciable deep-water circulation is therefore confined to the region of the South Pacific where, again, the Antarctic bottom water and intermediate water flow north. These waters are mixed with the great bulk of deep water which contains components of Atlantic and Antarctic origins which have passed to the south of the Cape of Good Hope and to the south of Australia and New Zealand. A return flow to the south takes place between depths of 2,000 m. and 3,000 m.

In the North Pacific the deep water is exceedingly uniform and the circulation sluggish, as evidenced by the low oxygen content of the water. Below a depth of 2,000 m. the salinity varies between 34.65–34.7‰ and the temperature between 2° C. and 1.5° C. A slight renewal of deep water probably takes place by exchange with the South Pacific, deep water moving slowly north in the western Pacific and south in the eastern Pacific. This motion is superimposed upon a general clockwise circulation which extends from the surface to the bottom but is slow below a depth of a few hundred metres.

Relation between Oceanic Circulation and Organic Productivity.—Around the Antarctic continent we find not only sinking of surface water but we also find that large volumes of deep water are drawn to the surface. These bring with them relatively high concentration of phosphates, nitrates and other plant nutrients, and the antarctic waters can therefore support a large amount of marine life. The waters are among the most productive of ocean areas, as evidenced by the large whaling industry which has developed in the antarctic since the turn of the century.

In general, regions of high productivity are found wherever an overturn of the surface layers takes place, regardless of the mechanism which brings about such an overturn. In parts of the North Atlantic, vertical convection reaches in winter to the bottom, and by this intense overturn the surface waters are well supplied with nutrients which, in summer when light conditions are favourable, can support enormous populations of diatoms and other minute marine plants.

In other regions of the North Atlantic and over large parts of the North Pacific, the winter convection reaches to depths of a few hundred metres only, but the mixing caused by this convection is sufficient to restore to the surface layers large amounts of plant nutrients and thus make possible a high productivity during summer. Upwelling (p. 690) has a similar effect, and the regions of upwelling off the coasts of California, Peru, Chile and southwest Africa, are also regions of high productivity.

The deep water of all oceans contains relatively large amounts of plant nutrients (see *Chemistry of Sea Water*, above). In the North Atlantic, the concentrations of these are lower than in any other ocean.

BIOLOGICAL OCEANOGRAPHY

The marine plants and animals should be thought of as a part of the sea, even as the salts are a part of the sea. They are intimately bound to its physical processes and are in themselves the activators of chemical changes that involve alternating phases of the mineralized and organic state of certain salts and gases so vital to biological, chemical and geological oceanography.

Historically, the early biological studies of the sea were exploratory and mainly descriptive. They were concerned largely with the systematic cataloguing of the different kinds of organisms found in the sea. This is still the natural procedure in the investigation of new areas. The exploratory-descriptive phase is exemplified especially by the great "Challenger" expedition of 1873–76 and by various expeditions of the U.S. fish commission steamer "Albatross" from 1883 to 1920. The descriptive phase, though far from complete for the oceans as a whole, is in many regions drawing to a close and, especially since the beginning of the 20th century, has given way to a second phase which is primarily analytical. The analytical phase is concerned particularly with the factors that are important in governing the biological economy of the sea. Some of these factors will be brought out in the course of discussion.

The sea is the world's largest biological environment. The available living space that it provides is about 300 times greater than that of the combined terrestrial and fresh-water environments. This results not only from its vast horizontal expanse (71% of the earth's surface) but especially from the great vertical range from the surface to great depths.

For convenience of study the marine environment is divided into two major divisions, namely, the benthic, comprising all of the bottom from high-tide level to abyssal depths, and the pelagic, comprising all of the water covering the bottom. The benthic division is subdivided into the littoral system and the deep-sea system, with the dividing line arbitrarily set at the 200-m. depth contour. The upper part of the littoral system to a depth of about 40 to 50 m. is the eulittoral. Its greatest depth corresponds to the lower limit for growth of the more abundant attached plants.

The population of the entire environment is divided into three major ecological groups: (1) the benthos, which includes all organisms such as seaweeds, barnacles, clams, crabs, etc., that live on the bottom, either attached, burrowing or creeping; (2) the nekton, consisting of the strong-swimming animals such as fishes, whales, etc., of the pelagic division; (3) the plankton, which includes floating plants and animals that possess little or no effective swimming power and are therefore carried more or less helplessly by the water currents. The planktonic forms are constantly in danger of sinking to unfavourable depths.

The plankton is divided into two main divisions: (a) phytoplankton, comprising the microscopic floating plants of which the most important are, first, the diatoms and, second, the holophytic dinoflagellates, the latter being a borderline group between plants and animals; (b) zooplankton, which comprises a multitude of floating or feebly swimming animals, mostly microscopic to a few millimetres in size.

From the standpoint of the economy of the sea, the phytoplankton and the zooplankton are the fundamental groups upon which nearly all sea life is dependent either directly or indirectly. This results from the fact that the floating diatoms and dinoflagellates are the chief synthesizers of primary food, while the animals that make up the zooplankton are the chief grazers utilizing this plant crop and converting it into animal substance for the use of carnivorous animals. For this reason, investigations of the oceans have been concerned largely with the ecological factors, physical, chemical and biological, that affect or control the production and utilization of these two fundamental groups.

All biological groups must, however, be carefully investigated,

for only thus can we hope to understand the essential interrelationships of the groups and to evaluate the part played by each in the various phenomena of the sea. (*See* MARINE BIOLOGY for other details.)

Factors of Phytoplankton Production (Organic Production).—Phytoplankton growth is dependent upon a number of more or less clearly defined interacting variable factors, one or more of which may be critical to production. The factors of production are either primary or secondary. The primary or direct factors are those concerned with the energy supply, food supply and rate of metabolism. They are light, nutrients, temperature and salinity, and control the growth and proliferation of the individual plant cell. Any one of them which, at the moment, is not optimal in relation to other factors in the water is a limiting factor. Thus, light is always a limiting factor at low intensities. The secondary factors control the density of the population, as discussed later.

Light, the radiant energy of the sun, is intercepted by the plant pigments and used in their manufacture of carbon compounds from carbon dioxide and water. In simple form, this is expressed by the equation $6CO_2+6H_2O=C_6H_{12}O_6+6O_2$.

In this endothermic reaction the resultant organic substance of the plant contains more energy than was present in the reactants CO_2 and H_2O. This extra energy derived from the sun is stored in the complex plant substance, later to become available as chemical energy for life processes of the plant and also, directly or indirectly, for that of all animals and heterotrophic bacteria.

The oxygen set free in the process of carbon assimilation is used in part by the plant, but the excess oxygen is an important source for the aeration of the upper layers of the sea. A 5-day period of lively diatom growth may, for example, increase the oxygen content of the water by as much as 2.2 ml. per litre.

Oxygenation by phytoplankton therefore has many far-reaching biological and chemical implications and has to be taken into account also when studying the "age" or source of water masses because the oxygen content is an index of past conditions.

Only the upper water layer, to depths of 80 m. or less, has sufficient light for the process of photosynthesis. This layer is known as the euphotic zone and varies greatly in depth depending upon latitude, turbidity and season. The depth at which the light intensity is just sufficient to bring about a balance between oxygen production and oxygen consumption during the process of photosynthesis is known as the compensation depth. It is the maximum depth at which the light intensity is sufficient for the plants to survive but not enough for crop increase.

It has been concluded by British investigators that for inshore waters of the latitude of Loch Streven, Scotland, the compensation depth in summer is at 20 to 30 m., while during the winter it is near the surface. In Oslo fjord it was at 10 m. during March. During midsummer in Puget sound it is between 8 and 18 m. Diatoms are often found below the compensation depth. They apparently have sunk there and, though some photosynthesis still takes place at this level, it is not sufficient for long survival.

The compensation depth, like the optimum depth for photosynthesis, is not the same for all species. In mid-latitudes the optimum depth for a mixed population is usually less than ten metres, but it is not at the immediate surface. Experiments indicate that the rate of photosynthesis is proportional to light intensities only at intermediate intensity of illumination. Diatoms exposed to intense light close to the surface sometimes concentrate their chloroplasts for mutual protection against the light. This is known as systrophe, and for *Coscinodiscus excentricus,* it takes place at a light intensity of about 9.69 cal. per square centimetre per hour.

Plant nutrients (*i.e.,* the dissolved nutrient salts) constitute the inorganic food supply of the plants. Chief among these are the compounds of nitrogen and phosphorus. The importance of these in the control of phytoplankton production was first anticipated in 1899 by K. Brandt. Subsequently, with improved methods of chemical analysis they have repeatedly been shown to fluctuate with periods of diatom growth. There is some evidence that iron may be a limiting factor for neritic (coastal) species according to H. H. Gran. Manganese and certain unknown accessory growth factors are known to be influential in promoting growth. At best, sea water is only a dilute nutrient medium but large concentrations are not needed. For example, a concentration of 10 mg. of phosphorus to 1,000 l. of water will produce a vigorous growth of diatoms when other factors are favourable.

The absorption of dilute nutrients is facilitated by the small size of the phytoplankton organism, because with reduction of absolute size there is an increase in the ratio of surface to volume. Thus, in comparing a plant 1 mm.^{3} with 1,000 plants of 0.001 mm.^{3} there is a tenfold aggregate increase in surface area of the smaller plants and a hundredfold improvement of conditions for diffusion of salts at these surfaces.

The silicates, used in building diatom shells, are drawn upon measurably during diatom growth, but it has not been shown that the reduction in silica is sufficient to constitute a limiting factor.

With each 10° C. rise in temperature, within favourable limits, the rate of metabolism is increased two- to threefold, according to Jacobus van't Hoff's law. In the mixed population of the sea the effect is not simple, however. The thermal requirements differ for different species, with the result that there may be a seasonal succession of different biological groups, each with its own optimal temperature range. Thus, certain diatoms flourish best during cool periods and are replaced by others as the waters become warmer. The warmth-loving dinoflagellates frequently dominate during the warmest periods.

Salinity is a factor significant mainly in maintaining favourable osmotic conditions between the organism and the water in which it lives. Some species are euryhaline (tolerate a wide range of salinity), others are stenohaline (tolerate only narrow limits). Hence, salinity is largely a selective agency determining the species composition rather than the crop production.

The secondary factors of phytoplankton production are mainly those controlling density of population. Under favourable conditions of light, nutrients and temperature, the increase in phytoplankton is extremely rapid, because the method of reproduction is by simple cell division. Through this reproductive habit the population increases by geometrical progression. Cell division may occur as often as twice a day. Nevertheless, the standing crop may at times be small despite favourable primary factors. Any circumstance that operates to withdraw large numbers of individuals must function as a check which affects materially the total numbers that can be produced in a given time. Among the obvious checks are (1) consumption by animals and (2) sinking or transport to unfavourable layers through action of gravity or adverse water currents.

1. Vast quantities of phytoplankton are consumed by the herbivorous zooplankton animals, especially by the copepoda. It has been observed by various investigators that large populations of phytoplankton and zooplankton do not usually exist concurrently in the same area. This disparity is believed to result primarily from heavy grazing by the abundant zooplankton in the area. An alternate hypothesis (animal exclusion) maintains, however, that thick clouds of phytoplankton (diatoms) are avoided by the copepoda, which seek depths below the euphotic zone. A difference in the rate or direction of flow of surface and deep water then tends to segregate the two groups.

2. The rate of sinking of a body heavier than water is controlled by the relation of surplus weight to friction. Most plankton organisms are heavier than water. The small size characteristic of these organisms is, however, an effective adaptation to their floating existence, for with reduction of absolute size there is provided a relatively large friction surface to retard sinking. But, despite this adaptation, there is still a constant loss through the effect of gravity. Many diatoms can be found below the compensation depth, and bottom sediments in certain areas are composed in large part of the shells of diatoms that were produced in surface layers.

A more rapid loss of plants from the zone of optimum light may occur in areas with strong turbulence in passages or channels where surface water and its passive population is shifted to depths of low light intensity. Ascending currents may bring them back to the lighted water, but the period spent by the plants below the com-

pensation depth is a total loss to production. Some degree of stability resulting from increased surface temperature or lowered salinity is therefore advantageous temporarily. However, the advantage gained may result in rapid depletion of the nutrient salts and an accompanying drop in production pending renewal of surface waters by diffusion or by water currents.

Water Currents and Plant Nutrients.—Coincident with the production of a heavy crop of diatoms, there is a sharp drop in the concentration of plant nutrients. Some nutrients are regenerated through bacterial action on dead organisms within the euphotic layer, but there is a continual sinking of organisms and organic detritus from this layer toward the bottom. This effects a serious withdrawal of the nutrient elements from the surface and an accumulation in the deeper water where, because of insufficient light, they cannot be used by plants.

Thus, a deep stratum of water overlying the ocean floor becomes a storehouse for mineralized plant nutrients. It is from this storehouse that (in accordance with A. Nathansohn's theory of 1906) the fertilizing minerals are brought to the lighted surface through the action of ascending water currents. These currents may be of somewhat different origin, but all are of utmost biological importance. In coastal waters, turbulence maintains a more or less steady supply of nutrients in the euphotic zone.

In offshore waters there are areas of divergence characterized by a flow of surface waters away from each other and a replacement by deeper water. Such areas are commonly productive. Conversely, the areas of convergence of old surface waters are relatively barren. In boreal regions the convection currents initiated by cooling and sinking of surface waters in autumn and winter replace the surface waters that were depleted because of summer plant growth under conditions of marked water stratification. In these regions there are frequently spectacular spring outbursts of phytoplankton production. Prolonged winds may shift the surface layers and cause temporary currents and upwelling on a small scale.

The renewal of nutrients on a grand scale through upwelling of deep water is exemplified by such areas as the west coast of Africa and South America. There the Benguela current and the Peru current, respectively, are laden with nutrients that give rise to notably abundant phytoplankton production that may extend far to sea with the flow of water outward from the coast. In general, coastal areas and shallow banks are more productive than the open sea because it is in these situations that the physical forces are most effective in bringing about renewal of surface water by nutrient-rich subsurface water. (*See* also p. 691.)

Environmental Factors and the Marine Animals.—All animals are of course indirectly dependent upon light for production of primary food. The development of sight has made many forms also directly dependent upon this factor. But the relative independence regarding solar light has made it possible for all depths of the sea to become populated by some type of animal life.

Many of the studies concerning the influence of this factor deal with its control of the vertical distribution of pelagic animals. Characteristically, the copepoda, chaetognatha, some fishes and many other forms have their daytime maximum concentration in depths of 50 m. or more, where the light intensity is much reduced. But with the approach of night many of these animals migrate gradually toward the surface, and return again to deeper water at or before dawn. This behaviour is commonly spoken of as diurnal migration and is a conspicuous phenomenon of the sea. There can be little doubt that light is the motivating stimulus, but its action appears to be in some way linked to geotropism (reaction to gravity). The response to light is not always the same for both sexes, and it sometimes differs also for different stages of development.

In the open ocean there is also a correlation between the amount of light and the colour of pelagic animals. At the surface the colours of fishes are largely silvery or white with backs of green, blue or black. Invertebrates of the plankton are commonly faint red, blue or hyaline. In mid-depths the fishes are silvery and the plankton animals are commonly red or of shades of violet and brown. In abyssal depths the colours tend to uniform shades of red, brown, violet-black or black, without the bizarre markings of shallow-water animals.

Many of the deep-sea forms have structural peculiarities that are associated with absence or reduction of solar light. Conspicuous among these structures are protruding eyes, long tactile organs and light-producing bodies.

Light production (phosphorescence) is not confined to deep-sea animals. Conspicuous among bioluminescent forms are the microscopic Dinoflagellata which live near the surface. At night the crest of waves or the wake of a ship may glow with blue-green light when the water is agitated, causing myriads of these tiny forms individually to emit short flashes.

Together with this glow are usually seen larger, brighter flashes caused by various types of jellyfish and small Crustacea. The light is produced chemically by oxidation of a simple protein called luciferin in the presence of a catalyst called luciferase.

With respect to temperature requirements, animals are either eurythermic, tolerating a wide range of temperature, or stenothermic, tolerating only a narrow range of temperature. Many are eurythermic in the adult stage but are stenothermic with respect to reproduction or to survival in the larval stage. The thermal relationships determine the range of distribution and the spawning season of many species inhabiting the sea. Usually the adults can survive a greater range of temperature than is favourable to successful reproduction, and for this reason they may have an extended area of sterile distribution. These areas are restocked regularly or occasionally by submature or mature migrants from adjacent reproductive areas. Where sharp temperature transitions are lacking along coasts, there also the faunal areas are poorly defined, as is true along the European Atlantic coast and the North American Pacific coast. It frequently happens that animals requiring low temperatures are found in the littoral zone in the higher latitudes, but in the sublittoral or deep-sea zones in the low latitudes. This is known as equatorial submergence.

The salinity of sea water is the one factor which above all others distinguishes the marine environment from other aquatic environments. Most other factors, excepting those associated with the magnitude and depth of the sea, can be duplicated in lakes or streams. Only a few animals like the salmon and eel can migrate, however, from one environment to the other.

Many euryhaline coastal forms can endure a marked reduction of salinity for extended periods, but will succumb if sea salts are entirely absent. The stenohaline species (capable of tolerating only a narrow range of salinity) are characteristic of the open ocean, where there are no marked variations in this factor.

In general the animals find an ample supply of oxygen produced by plants or dissolved from the air and distributed by the water currents. Even in the oxygen minimum layer in the open sea some planktonic animals have been found, despite almost complete absence of oxygen. In poorly ventilated basins or bays the decomposition of organic material precipitated from above may lead to exhaustion of the oxygen and development of hydrogen sulphide. In these toxic situations only anaerobic bacteria can exist.

The dependence of animals, directly or indirectly, on the circulation of water in the sea cannot be overstressed. The importance of this factor lies especially in the dispersal of wastes of metabolism, the aeration of the water, the renewal of plant nutrients, the distribution of temperature, the dispersal of temporary and permanent planktonic organisms and the transport of planktonic or detrital food to the many sessile or burrowing benthic animals.

The planktonic organisms, especially the eggs and larvae of the benthic animals (nearly all of which, excepting the deep-sea forms, have pelagic eggs or larvae), live a hazardous existence. They are always in danger of being transported to areas of unfavourable water or to bottoms or depths that are inimical to the adult stage following the period of floating life.

To overcome this hazard the species with planktonic young produce a prodigious number of eggs. In current systems that form a closed or semiclosed circuit, or where the currents are mainly oscillations of the tide such as occur in deep bays or along the coasts, the planktonic population is largely endemic; its whole life history can be studied within the area. Frequently plankton from

THE MAIN FEATURES OF THE INTERRELATIONS OF MARINE ORGANISMS

outside areas are swept more or less regularly into these situations, or some of the local population may be swept out.

If the change in conditions is not too great, the migrants may live as adults in the new environment, but they are usually incapable of successful reproduction. The animals that have drifted from their endemic area are known as indicator species and are frequently a material aid in studying the source of water masses. Large current systems—for example, the Gulf stream and North Atlantic current—are capable of maintaining a characteristic endemic population of warm-water species. But upon cooling and by admixture of water from the north, the warm-water species are gradually replaced by the cold tolerant boreal or arctic forms.

The Role of Bacteria in the Sea.—The role of bacteria in the metabolism of the sea is concerned mainly with transformations of organic material to the inorganic or mineral state and not with the production or storage of organic material. There are a few autotrophic marine bacteria (capable of synthesizing organic material), but the organic material produced by them is negligible. Most bacteria in the sea are heterotrophic; *i.e.*, they obtain their energy for life processes through the oxidation of organic compounds. These compounds may be in the particulate state as plant or animal tissue, or they may be in solution in the water.

There is evidence that the organic matter in solution in the sea is several times greater than that occurring as a standing crop in the particulate state. The concentration of the dissolved matter is remarkably uniform, and it is believed that the upper limit of concentration represents a threshold value maintained at a level below ten milligrams per litre by the bacteria.

Since plants use only the mineralized nutrients, this reclaiming of dissolved matter by conversion to simple mineralized plant nutrients by bacteria is essential to the biological cycle of the sea. Equally important are the transformations through bacterial decomposition of the particulate organic matter.

In the process of bacterial decomposition of organic material, a series of steps is involved, each with its specific types of bacteria. Thus, a step in the nitrogen cycle is the simplification of the organic molecule by splitting off the NH_2 group from the amino acids. Many types of bacteria can do this. At this point the nitrogen may be assimilated by the diatoms.

However, the cycle is usually carried forward by the nitrifying bacteria forming nitrates from ammonia and nitrites ($NH_3 \rightarrow NO_2 \rightarrow NO_3$). Ammonia may also be oxidized to nitrite photochemically. The cycle is somewhat further involved by the presence of nitrate-reducing and -denitrifying bacteria, which may reverse the chemical process at least in part ($NO_3 \rightarrow NO_2 \rightarrow N_2$).

This is believed to occur in environments lacking or poor in oxygen, where the bacteria obtain their oxygen by reducing these compounds. True denitrifiers and also nitrogen fixers appear, however, to be unimportant in the economy of the sea.

Phosphorus, carbon and sulphur cycles are also activated by bacteria. In experiments, the phosphates are quickly regenerated, but renewal of this nutrient in nature appears to require three to four months.

The carbon of organic compounds is returned as carbon dioxide, which is always present in ample quantity for plant growth. A small amount of sulphur is used by plants in the form of sulphates, but an important product of organic decomposition is hydrogen sulphide which, when present in large quantities, is inimical to plant and animal life.

The distribution of bacteria in the sea is governed by the distribution of particulate organic material. Hence, two centres of large bacterial populations occur. One of these is within the euphotic zone, where the phytoplankton and zooplankton are abundant. The second is on the bottom, where organic material accumulates as a result of sinking of plankton and nekton from the overlying water. Most bacteria are periphytic; *i.e.*, grow attached to solid surfaces such as diatoms, copepoda and sand grains. Therefore, relatively few appear to be truly planktonic.

The outstanding features of the interrelations of marine organisms and of the organic-inorganic cycle are diagrammatically shown in the figure.

Measurement of Organic Production in the Sea.—Gross organic production is defined as the amount of organic material synthesized from inorganic material by autotrophic organisms in unit time in unit volume of water or unit area of sea surface.

The indices of production commonly used are briefly as follows:

1. *Direct census.* By this method the individual plants (diatoms or dinoflagellates) from a known quantity of water are counted under a microscope, and the results are reported as cells per litre or cubic metre of sea water *in situ*. Counts from isolated observations are, of course, only measurements of the standing crop. To obtain an estimate of production for an interval of time, successive samples are needed, together with data on the rate of reproduction and consumption in the intervening periods.

This method, though essential to the analysis of the biological groups, is not adequate by itself to show the volume of production, hence complementary methods, mainly chemical, are used.

2. *Plant pigment analysis.* This consists of extracting (with acetone) the pigments from the plants of a known volume of water and thus determining the pigment units, each unit being equivalent to 3.3×10^{-3} mg. of organic carbon.

3. *Oxygen production.* For each 0.536 mg. of carbon assimilated by the phytoplankton there is set free 1 ml. of oxygen. One experiment in the Gulf of Maine showed a maximum production of 2.33 ml. per litre of oxygen at the surface in about nine hours, while the whole water column 1 $m.^2 \times 44$ m. deep produced 29.1 l. of oxygen; *i.e.*, a fixation of 15.6 gr. of carbon.

4. *Plant nutrient consumption.* A rather constant ratio exists between carbon, nitrogen and phosphorus in the organic content

of mixed plankton. The ratios C:N:P=41:7.2:1 by weight are about the same as it is for these elements in sea water. The drop in concentration of the mineralized state of any of these elements in sea water over a period of time is therefore a good index of the extent of synthesis of organic substance that has taken place (plus an unknown quantity equal to the nutrients that have been regenerated during the period).

Other estimates of organic production are based upon the quantity of animals. Plants, of course, are the only real producers in the sea, but the quantity of animals produced in a given area must depend upon the capacity of the area to produce plants. Therefore, the productivity of an area may be judged roughly by the amount of zooplankton it supports or, in some instances, by the products of fisheries.

Zooplankton is usually reported as numbers of cubic centimetres per cubic metre of water or per square metre of ocean surface. In the Gulf of Maine, where the copepod *Calanus finmarchicus* dominates the plankton, the concentration of this animal was found to be from 0.2 to 5.3 cc. per cubic metre over a large part of the gulf. The standing crop of the copepod plankton for the whole gulf was of the order of 4,000,000 tons. The crop increase between May and September was a net gain of 8,000,000 tons.

The correlation of fisheries products with plankton production is especially evident in connection with the plankton-feeding fishes such as the sardine, herring, etc., and with the catches of whalebone whales. Off the coast of California, for example, the upwelling of water at the coast gives rise to a rich crop of phytoplankton and zooplankton, and from this area about 550,000 tons of sardines alone have been fished in a year. This is equivalent to more than a ton a minute throughout the year.

Great whaling operations are carried on in the waters of the Antarctic, the feeding grounds of the blue whale and other species that feed upon the animal plankton.

The waters of these areas are also notably rich in plant nutrients and in phyto- and zooplankton.

The abundance of benthic animals in many coastal areas, and in rich inlets such as Puget sound, is also a reflection of the heavy plant production which takes place there. In contrast, there is a scarcity of benthic life in great ocean depths. This scarcity results partly from the small production of plankton in the surface waters of the open sea (as explained earlier) and partly from the dissolution of the surface products before they reach the bottom in their course of sinking.

OCEAN CITY, a city of Cape May county, southeastern New Jersey, U.S., about 10 mi. S.W. of Atlantic City, is served by the Pennsylvania-Reading Seashore lines. The population was 6,040 in 1950 and 4,672 in 1940 by the federal census. Located on the northern end of Peck beach, a barrier beach along the Atlantic, the city is flanked by Great Egg Harbor bay on the west and the ocean on the east. It offers the advantage of convenient access to both the ocean and calm inland waters and became a popular summer resort.

It was connected by bridges with Longport to the north and Somers Point to the west. There are truck farms in the area. The city was incorporated in 1897.

OCEAN CITY is also the name of a resort town and port of Worcester county, southeastern Maryland, 28 mi. E. of Salisbury. Pop. (1950) 1,234. It is noted for big-game fishing.

OCEAN GROVE, a summer resort of Monmouth county, New Jersey, U.S.A., on the Atlantic coast, adjoining Asbury Park on the south. It is served by the Central of New Jersey, the New York and Long Branch and the Pennsylvania railways and motor-coach lines. The resident population in 1950 was 3,806. There are many hotels, private cottages and a mile of boardwalk along the sea front. Ocean Grove was founded in 1869 by the Ocean Grove Camp-Meeting association of the Methodist Episcopal Church as a place for religious worship, rest and recreation, free from all kinds of undesirable amusements, and it keeps much of its original character. Vehicular traffic (except police, fire, ambulance and physician) is prohibited on Sunday.

OCEANIA, a geographical area extending from Australia, in the west, to the most easterly islands of Polynesia, in the east, and from New Zealand, in the south, to Micronesia and the Sandwich islands, in the north. Ethnologically the area is divisible into six principal regions (*q.v.*): Australia; Tasmania; Melanesia, a group of islands extending from Fiji, in the south-east, to New Guinea, in the west; New Guinea, which, however, is a geographical rather than an ethnological unit, for the eastern and north-eastern coastal regions are Melanesian, while the west really falls under Indonesia; Polynesia, an island area of considerable racial and cultural uniformity, comprising the greater part of the Pacific; Micronesia, an island area comprising that part of the Pacific which lies between New Guinea, Polynesia and the Philippines.

Racial History.—There is little doubt that man first entered this area from the west, and subsequent migrations have all had an easterly, or, in the case of Australia, a southerly trend. The problem of dissecting out the racial components of the peoples on the eastern and southern periphery is, therefore, comparatively simple. Furthermore, the uniformity, both of physical type and culture, and evidence of a more or less historical kind, show that the Polynesian area is of comparatively recent occupation, even allowing for more than one principal set of migrations. But in New Guinea and Melanesia, the principal gateways into Oceania, conditions are more complex, and the racial history of this area has been only tentatively elucidated. Australia, again, shows considerable physical and cultural uniformity with many variations, but the existence of varieties of the Papuan type of man in Tasmania, with a very primitive culture, suggests that man entered and crossed the length of Australia at an extremely early date.

Principal Groups.—The six principal divisions of this region, Australia, Tasmania, Melanesia, New Guinea, Polynesia and Micronesia, can be fairly readily distinguished from one another, both racially and culturally, though, in the case of New Guinea, there is not that racial and cultural uniformity which characterizes each of the other areas. Apart from New Guinea, with its great diversity of race and culture, some general characterization of culture as well as race can be made of each of the other areas. Language, for example, will readily separate Australia, and in all probability Tasmania, from the group Melanesia, Polynesia and Micronesia. The speech of these three areas, together with the Melanesian and Indonesian part of New Guinea, is clearly referable to one family, the Austronesian (*q.v.*), extending from part of India and Burma, through Malaya and Indonesia to the extremities of Polynesia. But while the Polynesian languages may be described as dialects of one language, there is considerably more diversity within the Melanesian sub-division of this family.

This Austronesian speech is associated with a distinctly higher culture, particularly in Polynesia and Micronesia, the Melanesians being in some respects intermediate between these groups and the Papuans of New Guinea, though among Papuans there is great variety of culture, the result, no doubt, of various degrees of blending of immigrant cultures with perhaps more than one indigenous culture brought into New Guinea and Melanesia by the original Papuans.

The Australians, culturally as well as physically, betray a marked contrast, not only with the Austronesian-speaking peoples of Oceania, but also with the Papuans of New Guinea. Horticulture, well-developed throughout the rest of the area, excepting Tasmania, is entirely absent, and the economic life is, consequently, of a very low order. Nevertheless, an elaborate social organization and ceremonial life and considerable variation in such stable aspects of culture as the disposal of the dead, survive in Australia.

Mode of Life.—The Australians and Tasmanians, being hunters and collectors, are necessarily nomadic, though within more or less well-developed tribal areas. Their most important possessions are their hunting weapons, spears, boomerangs and tools rudely chipped out of stone. The aridity of most of Australia during the greater part of the year, and the very short period during which nature provides abundant food, cause most of the non-economic activities of the Australians to be concentrated in the brief period of spring, when magico-religious rites with the object of increasing the food supply are performed, initiations are conducted, and, in fact, most of the tribal, in contrast with family, activities take place.

In the rest of the area, with its basis of horticulture, the economic struggle is not so keen, and the population is a settled one, except for a few nomadic or semi-nomadic peoples in New Guinea. Diet is mainly vegetarian, taro, yams, bread-fruit, sweet potato, coco-nuts, sago and bananas being the principal foods. In island and coastal regions fish is largely consumed, and almost everywhere pigs are reared and reserved for consumption on occasions of importance, such as marriage festivals and mortuary feasts. Although cannibalism is common, the eating of human flesh is usually a ceremonial act of revenge, or associated with mortuary or other rites. Canoes capable of long sea voyages are constructed, principally in the island areas. Double canoes, and outrigger canoes of various patterns and, formerly, double canoes which only survive at the present day in a limited part of New Guinea, are the commonest, the larger ones being provided with sails. While intercommunication is much hampered by warfare, goods are traded over considerable distances, and in many areas well-developed systems of currency occur.

Social Organization.—One feature of social organization appears to be common to the whole of this area, namely, the systematic non-genealogical use of relationship terms, generally known as the classificatory system. If we select any person in a village and enquire as to his relationship to others in the village, he will rarely be at a loss, for everyone is likely to be a mother, or a brother, an uncle or a father-in-law, etc., in this classificatory sense, and such relationships will be found to hold to a large number of persons in other more distant villages. Moreover, these classificatory relationships are important determinants of conduct, many rights and duties being dependent on relationship, though when the relationship is very distant in the classificatory sense they are hardly distinguishable. One of the most important functions of this relationship system lies in the regulation of marriage, those lying in certain relationships being prohibited from marriage, while in some cases only those persons who can establish a given relationship between themselves are allowed to marry. Marriage, however, is generally regulated, at least in part, by the clan (*q.v.*) which is usually, throughout this area, the most important social unit. Particularly in Australia, Melanesia and New Guinea, and to a slightly less extent in Polynesia, is the clan a fundamental unit of the social structure. Membership of the clan is determined by descent through the father or the mother, both varieties being common, and marriage is prohibited within the clan. As a rule, the clan is also totemic (*see* TOTEMISM), this totemic aspect being peculiarly important in Australia, where totemic rites form a large part of the ceremonial life of the natives. In parts of the area, especially Australia and Melanesia, the clans are grouped into two exogamous moieties (*see* DUAL ORGANIZATION), and there is some evidence which suggests that a dual organization once extended over most of the area or occurred among their ancestors before their migrations into Oceania.

Political Organization.—In Australia and parts of Melanesia, age appears to be an important qualification of leadership, councils of elders deciding matters of tribal importance. In parts of Melanesia there is little vested authority, a more or less communistic system prevailing, while in other parts, authority depends on the acquirement of prestige derived from the holding of feasts, or the acquisition of wealth. Hereditary chieftainship is

common in Polynesia, where a considerable social gulf may exist between nobles and commoners.

Initiation.—Ceremonies of initiation into manhood occur amongst Australians and many Papuans, and are found amongst some Melanesians, mainly in connection with secret societies (*q.v.*), which in some cases dominate the social organization.

Religion.—The belief in spirits of the dead is general throughout this area, and some degree of cult of the dead is present everywhere. In some cases, mortuary ceremonial reaches a very high degree of elaboration, particularly in the case of chiefs. Violent orgies of mutilation on the occasion of a death are reported from Australia, and in extreme form from Polynesia. But the existence of an elaborate mortuary ceremonial is not necessarily associated with anything that can be called a worship of the dead, which is probably confined to Polynesia, parts of Melanesia and Micronesia. Between spirits of the dead, or ghosts, and spirits or gods not definitely associated with some ancestor, there is no sharp line of demarcation, but sometimes there are separate words for these two kinds of beings, and a different cult is associated with each, a practice common in Melanesia. Certain ghosts or spirits may be of sufficient importance to rank as gods, who are able to affect more or less the destinies of man, or who are credited with having performed certain acts of creation, or to have introduced important foods or new customs. An elaborate mythology centres around these culture heroes throughout the area, and provide us with suggestive hints as to culture movements and culture contacts in the past.

There is, perhaps, more uniformity throughout the area in the realm of magic (*q.v.*) than in that of religion, in so far as it is possible to separate the two, for there is a transparent sympathetic basis of almost all the magical practices. In addition to direct sympathetic magic without the aid of ghosts or spirits, we also find, particularly in Melanesia, the coercion of both ghosts and spirits for the attainment of what are usually anti-social ends. Divination of sorcerers is also common, which, together with fantastic beliefs concerning the powers of sorcery, accounts for a good deal of the strain to which social relations between individuals, and between groups is subjected in this part of the world. One of the commonest causes of murder is revenge for supposed sorcery.

BIBLIOGRAPHY.—The separate articles, AUSTRALIA, etc., should be consulted for the bibliography of this region. For the racial history, *see* A. C. Haddon, *The Races of Man* (Cambridge, 1924). In Sir J. G. Frazer, *The Belief in Immortality* vols. i.–iii. (London, 1913–22–24), there is a good account of the chief features of social organization and religion of the principal groups within Oceania.

(W. E. A.)

ARCHAEOLOGY

From permanent contact with European settlers in the latter part of the 18th century the transition from the Stone to the steel age was rapid. Previously writing was unknown in the area, if we except the pictographic "script," as yet imperfectly explained, of Easter island (*q.v.*).

Although it is improbable that any of the more important monuments have entirely escaped observation and record, the greater part of the area has never been properly surveyed in an archaeological sense, and the published records available for many islands are meagre and of unequal value. The only islands of which anything like detailed surveys have been published are Easter, the Australs, the Marquesas, Hawaii (some islands), the Carolines (Ponape, and Kusaie) and, in part, New Zealand and the Chathams (*see* Bibliography). Surveys of Tonga, Tahiti, Necker I., Rapa-iti, and some smaller islands (Fanning, Malden, Christmas, etc.) are now in preparation by the Bishop Museum, Honolulu.

Absence of Palaeolithic Culture.—In the moist climate, perishable objects were quickly destroyed, and pottery being absent in Polynesia (except Fijian vases introduced into Tonga), the materials for archaeological study are practically limited to stone tools and monuments. No evidence of a Palaeolithic culture has been found in any part of Oceania. The prevailing tools are everywhere axes or adzes of stone (occasionally also of shell), polished wholly or in part, although flaked obsidian was also used in certain islands where it occurred (*e.g.* Easter, New Zealand, New Britain), and roughly flaked quarrying tools bearing a superficial resemblance to palaeolithic hand-axes are found in Easter island. Judged by its tools, the prehistoric culture of the area belongs entirely to the neolithic phase.

The ethnographical division into Melanesia and Polynesia holds good, in the main, for archaeology. In the former region adzes are of the "celt" type and rounded or sublenticular in section; in the latter they are predominantly straight-edged and angular in section, and further subdivided into a tanged and tangless type, characteristic of east and west Polynesia respectively. The distribution of monuments is in substantial agreement with that of the tools, and the elaborate structures of masonry characteristic of Polynesia scarcely occur west of Fiji, where the few stone monuments found are crude and megalithic in character. Exceptions in the Solomon and Banks islands may be regarded as relics of Polynesian migrations eastwards, or as due to later reflex movements.

Absence of Stratified Sites.—No stratified sites showing culture sequence, except in a minor degree in New Zealand, have been found. The habit of making funerary offerings seems to have been little developed, and grave-goods, where discovered, do not differ markedly from artifacts of recent date. Only in parts of Melanesia has the occurrence of deposits distinct in character from the products of the historic inhabitants been observed.

POLYNESIA

In Polynesia there is at present little archaeological evidence of a succession of cultures; monuments and implements represent at most an earlier and, in some cases, a higher phase of the culture that continued into historic times. Exceptions do occur, however; adzes of distinctively Melanesian type, found in Tahiti, and the carvings of bird-headed men in Easter island suggest the possibility of a pre-Polynesian occupation of parts of eastern Oceania by the negroid race. The evidence is too scanty to be entirely convincing, and the presence of a strong negroid strain in the inhabitants of eastern Polynesia is more probably due to racial intermixture during the Polynesian migrations through Melanesia than to a fusion in the islands in which it is found.

Eastern Polynesia.—In all the island groups east of Tonga and Samoa, without a single important exception, occur the remains, now more or less ruined, of megalithic structures, the sacred places or *marae* of the Polynesians. These consist typically of paved rectangular enclosures, surrounded by stone walls, and containing one or more rectangular stone platforms, sometimes, as in Tahiti, of stepped pyramidal form. The elements were variously combined, and differ in details of construction, contour and size. Thus in the Marquesas the walls are low or absent, in the Australs the platforms are generally lacking, while in Tahiti and Hawaii all features are generally present. The platforms were faced with large boulders or hewn blocks of stone or coral, sometimes weighing many tons, and often neatly fitted in regular courses, although mortar was never employed. The core consisted of earth or rubble, and sometimes contained burial pits or vaults. Platforms served also as substructures for sacred houses built of perishable material, for the exposure of the dead, as sacrificial altars, etc.; and the question whether they were intended primarily as tombs has yet to be settled by excavation. Many of them were originally surmounted by large figures of wood or stone in conventionalized human form. Such stone figures, some still *in situ,* are found in Hawaii (Necker), Easter island, Pitcairn, Tahiti, and the Australs (Raivavai), and in the Marquesas, where they exactly resemble those carved in wood. In the Marquesas, platforms, which always had vertical sides, were also much used for secular purposes, both in public assembly places (*tohua*) as seats for the spectators of dances, and as foundations for the ordinary dwelling-houses. The extreme development of terraces and platforms in the latter islands is due to the scarcity of level ground in the steep and narrow valleys, and to the abundance of suitably shaped boulders and easily worked volcanic stone. The largest recorded platform, that of Oborea, in Tahiti, now almost destroyed, measured 90 by 29yd. at the base, and rose in 10 or 11 steps to a height of about 50ft.;

but in general these structures did not exceed 12ft. in height. The antiquity of particular structures cannot be determined from internal evidence, but they were presumably built by ancestors of the historical Polynesians, who on traditional evidence did not reach the area earlier than the 7th century A.D. The fact that they occur in similar form in all groups, including Tahiti and Hawaii, which remained without intercommunication after the great voyages of the 13th and 14th centuries, as well as on intermediate islands, afterwards uninhabited, like Malden and Fanning, shows that the type must have been fully developed by the time of these voyages. Many were still in use when discovered, and some were even constructed in the historic period.

In Pitcairn island, which was uninhabited when occupied by the mutineers of the "Bounty" in 1789, are found many traces of a former Polynesian settlement. The *maraes* and stone figures are said to resemble those of Easter; but a number of large stone chisels and broad-edged axes dug up in the soil are quite exceptional in type. Other small islands, uninhabited at the time of their discovery, but bearing evidence of former Polynesian settlement, include Palmerston, Flint, Malden, Christmas, Fanning, Necker (Hawaii).

Western Polynesia.—In Samoa and Tonga typical walled *maraes* are not found, but in the former island there are numerous flat-topped mounds and platforms of considerable antiquity. Some of these were substructures for temples; others were used for burial. But certain earth and stone mounds of exceptionally large size, in Upolu and Savaii, appear to have been constructed for defensive purposes. One of these, near Apia, measures approximately 100yd. square at the base and is 35ft. high; it is traditionally supposed to have served as a platform for the houses of Tongan chiefs. In the mountainous interior of Upolu (Samoa) is a group of upright basalt slabs on a paved floor (*O Le Fale-o-le-Fe'e*), evidently the supports of a former house or temple, while in Savaii there are remains of roads and raised causeways elaborately engineered but long disused, and partly destroyed by an overflow of lava.

The most striking example of a true megalithic monument is the trilithon (Haamonga) on Tongatabu; it consists of two uprights and a lintel stone mortised into them, 15ft. high, and is stated by tradition to have been erected in the 13th century by Tui-ta-Tui in connection with a Kava feast. Not far distant are a large upright slab and two stone-faced house platforms. On the north coast of Tongatabu are the equally remarkable "tombs of the kings" (*langi*), formerly reserved for the burial of sacred chiefs called "Tooitongas"; these are stepped or terraced platforms containing burial vaults and are faced with hewn coral blocks measuring up to 22ft. in length. The earliest of these also probably date from the 13th century, but the construction of similar tombs continued down to the middle of the 19th century. Some of them are merely enclosures of rough stones.

Stone fortifications occur on many islands, and reach their highest development in the terraced entrenchments and solid stone towers on the mountains of Rapa-iti. Of the petroglyphs, representing stylized human and animal figures, concentric circles, etc., which are found abundantly in Hawaii and the Marquesas, some by their situation seem to have had religious significance, while others are only "travellers' marks"; many are of recent date.

New Zealand and Chatham Islands.—The final settlement of New Zealand by Polynesian immigrants from Rarotonga in the 14th century was preceded by an earlier branch of the same race, possibly also by people of Melanesian affinities, though this is disputed. Archaeology throws little light on this question, except in so far as no adzes of Melanesian type have been found in the older deposits. Only one properly stratified site has been excavated, viz.: Moa-bone Point Cave, near Christchurch, Otago, where the remains found in the lowest stratum prove the early inhabitants to have hunted the extinct moa. Although accurate dating is impossible, considerable antiquity is suggested by the fact that the coast has sunk several feet since the deposits were formed. The rock-paintings and the implements, which include knives, saws, drills, spear-points and finely "retouched" scrapers, of quartzite, obsidian, chalcedony and chert, indicate that the culture of the moa-hunters did not differ essentially, except in its higher standard of craftsmanship, from that of the historical Otago Maori.

The earthwork and stone fortifications belong for the most part to Maori (*q.v.*) culture, as do probably the pit dwellings and terraces of the Pelorus and Auckland districts and the artificial caves and figures carved in the soft tuff of Rotorua. Curious figures incised in a sandstone pit in Auckland and rock-carvings in the Kaingaroa plains representing canoes of modified Maori type are among the more interesting recent discoveries. The Chatham Islands appear to have been colonized by pure Polynesians, the extinct Moriori (*q.v.*), coming from the South island of New Zealand in about the 12th century. Their stone implements resemble Maori types, with the exception of tanged obsidian blades; tree-carvings and much weathered bird figures incised on cliffs have been reported.

MICRONESIA

The most important monuments of Micronesia are found in the Caroline islands, where both on Ponape and Kusaie extensive groups of buildings intersected by canals were constructed on artificially enlarged reefs protected by sea-walls. They take the form of rectangular paved courtyards, frequently in contiguous clusters, constructed by laying natural columnar blocks of basalt lengthwise and crosswise in alternate layers. These walls rise in places to a height of more than 20ft., but were not roofed. The enclosures formerly contained houses of perishable material, traces of which remain; also platforms, terraced or pyramidal, in which were sepulchral vaults roofed with coral or basalt slabs. The most striking and best preserved of these structures is the royal cemetery of Nan Tauach at Matolenim (Ponape), which stands in a double enclosure and contains four burial chambers. Enclosed burial platforms of a somewhat similar type occur farther west in Yap and the Bunaj islands. They have certain elements in common with the *marae* of Polynesia, to which they are possibly related either directly or as collateral branches from the same cultural stem. Although the date at which these "sacred cities" of the Carolines were begun is not clear, they were still inhabited at the time of their discovery, and the tradition of how they were constructed by means of inclined planes of tree trunks survives. The stone pounders, and shell and other objects found in the tombs, do not suggest a high antiquity.

In several of the Marianne islands occur groups of conical pillars called *Lat'te*, of square-cut coral, surmounted by large hemispherical capitals, and constructed either of monoliths or layers of coral cemented together. These are always arranged regularly in two parallel rows, and the most probable explanation is that they were supports for the floors of raised temples or houses, since destroyed. Remains of a burial have been found in a cavity in one of the capitals, but this was presumably only a secondary usage. The largest, in Tinian, are 15ft. in height with capitals 6 or 7ft. in diameter; those of Guam and other islands are much smaller. Associated with these monuments, and suggestive of some ceremonial purpose, are remains of burials, pottery, stone mortars and other artifacts.

MELANESIA

In various parts of Melanesia, from New Guinea to Fiji, are found relics of a prehistoric culture or cultures, which cannot as yet be dated or correlated satisfactorily. An important region covers the east end of New Guinea, New Britain and the adjacent archipelago, where the remains found include ornamented pottery (somewhat similar to that of prehistoric Japan), engraved skulls, obsidian implements and stone pestles and mortars, some of which occur at a considerable depth in river gravels and all of which are quite distinct from the products of recent inhabitants. In the same region, but within a more limited area, are low stone circles, lines and heaps of stones, now used as squatting places and, in part at least, of recent origin. Rock paintings and engravings are numerous in the district behind Port Moresby, some of them coated with a film of calcium carbonate, indicating a certain antiquity. Megaliths are widely distributed and irrigation terraces are found throughout Melanesia. In the Solomon islands (Bou-

gainville and San Cristoval) upright stones occur singly and in groups; in San Cristoval some villages are bordered with stone walls or platforms, and numerous stone-faced and earth mounds, containing shafts leading to burial chambers, and sometimes surmounted by stone statues, small dolmens or upright stones, are still in use. They may be related to Polynesian burial platforms. Their form and the mortuary customs associated with them have led to a comparison with early Egyptian mastabas; attention has also been called to a supposed resemblance of certain pig-tail figures to Egyptian royal statues, but this seems too remote to justify the emphasis laid upon it by some authorities. In the New Hebrides the antiquities include menhirs, stone sacrificial "tables" or dolmens, walls and high platforms, and obsolete types of pottery ornamented in a great variety of styles. There is an exceptional development of stone walls and buildings in the Banks islands, some, however, of recent construction. In general, chronological evidence is almost entirely lacking for these monuments, and the difficulties of distinguishing between ancient and modern are increased by the fact that parts of Melanesia are still living in a "megalithic period." In New Caledonia stone statues (in caves in Lifu) and a few "dolmens or trilithons" have been reported. Petroglyphs are common to all these groups, and particularly numerous in New Caledonia, where they take the form of human and animal figures, spirals and other patterns. Some of the better structures may be attributed either to late waves of Indonesian immigrants, or to reflex Polynesian influence, which has affected many of these islands in comparatively recent times; the *nanga* of Fiji so closely resemble Polynesian *marae* as to leave no doubt of their common origin.

Migrations and Hypotheses.—There is general agreement, on the evidence of oral traditions supported by physical, linguistic and botanical evidence, that the ancestors of the Polynesians—a composite stock including Caucasian, Mongolian and Negroid elements—must have come originally in a series of migratory waves from the Asiatic continent. Their starting-point cannot be definitely fixed; hypotheses vary as between India (Ganges or Chota Nagpur), Assam, and the Cambodia-Siam region of Indo-China. In favour of the latter view is the fact that a people speaking an allied language (Mon-Khmer) and having physical affinities with the Polynesians is still living there. They had probably settled in the Indonesian archipelago by the latter part of the first millennium B.C., whence they proceeded in at least two main streams of migration by way of Melanesia or Micronesia to Fiji, which they reached in about the 5th century A.D. Thence eastern Polynesia and New Zealand were settled in successive voyages during the 7th to 14th centuries. Hawaii seems to have been reached first by a direct migration from Indonesia and subsequently by a branch of the main wave from south-eastern Polynesia; this conclusion is supported by archaeological study which recognizes two distinct types of *heiau* (*marae*), the later of which corresponds more closely with the Tahiti-Marquesas type.

The hypothesis that Oceania served as a highway for the diffusion of an "archaic civilization," originating in Egypt in the 3rd millennium B.C., and including the practices of sun worship, mummification and the building of megalithic structures; and that the stone monuments of Oceania are attributable to the bearers of this culture-complex, has been a subject of considerable controversy. If tradition is right in asserting that Polynesian migrations did not reach the eastern Pacific before the 6th or 7th centuries A.D., and if, as appears probable, these people were the builders of the monuments in that area, it is evident that the older civilizations of America cannot have been inspired by them. On the other hand, since they were in contact with Asia till a relatively late period, they can hardly have escaped the influence of old-world culture or have failed to carry some of its elements with them into the Pacific. The view that Oceania was peopled by migration from America finds little support at the present time. But the theory has recently been advanced that the monuments and culture of eastern Oceania may owe something to the influence of Central and South America, the coasts of which were quite probably visited by the intrepid Polynesian navigators. The absence of pottery has been used by others as an argument for the very early isolation of the Polynesians; the loss of this art was, however, an inevitable result of prolonged wanderings among coral islands, where the material with which to practise it was not available.

OCEANUS, in Greek mythology, the river which encircles the earth (conceived as flat) (Gr. 'Ωκεανός). Beyond it, to the west, are the land of the Cimmerians, where the sun never shines, the country of dreams, and the entrance of the underworld. Oceanus is in Hesiod (*Theog.* 133, 337–370) the son of Uranus and Ge, the husband of Tethys, father of 3,000 streams and 4,000 ocean nymphs. In Homer he is the origin of the gods. Herodotus and Euripides use the word in practically the modern sense of *ocean; see* OCEAN AND OCEANOGRAPHY.

OCELLUS LUCANUS, a Pythagorean philosopher, born in Lucania in the 5th century B.C., perhaps a pupil of Pythagoras himself. Stobaeus (*Ecl. Phys.* i. 13) has preserved a fragment of his Περὶ νόμου (if he was really the author) in the Doric dialect but the only one of his alleged works which is extant is a short and unauthentic treatise *On the Nature of the Universe.*

Editions of the Περὶ τῆς τοῦ παντὸς φύσεως, by A. F. Rudolph (1801, with commentary), and by F. W. Mullach in *Fragmenta philosophorum graecorum,* i. (1860); H. Diels, *Die Fragmente der Vorsokratiker* (4th ed., 1922); Eng. trans. (1831) by Thomas Taylor. *See* also Überweg, *Grundriss der Gesch. der Philosophie,* Bd. i. (1926).

REDRAWN FROM A PHOTOGRAPH, N.Y. ZOOLOGICAL SOCIETY

OCELOT (FELIS PARDALIS)

OCELOT, a wild cat (*Felis pardalis*), ranging from Texas to Paraguay. The short smooth fur is ochraceous brown above, marked with numerous black-bordered blotches which tend to form oblique bands. The underside and feet are white. Ocelots reach a length of about $3\frac{1}{2}$ ft., while the tail is 18 in. They live in forests and are ready climbers. Cranially, the ocelot resembles the larger cats, with flattened profile and a strong sagittal crest. (*See* CARNIVORA.) (J. E. HL.)

OCHINO, BERNARDINO (1487–1564), Italian Reformer, was born at Siena. He entered the order of Observantine Friars, the strictest sect of the Franciscans, and rose to be its general, but, craving a yet stricter rule, transferred himself in 1534 to the newly founded order of Capuchins, of which in 1538 he was elected vicar-general. In 1539 he delivered at Venice a remarkable course of sermons, showing a tendency to the doctrine of justification by faith, which is more marked in his *Dialogi VII.* published soon after. He was suspected and denounced, and when the Inquisition was established at Rome, Ochino was at once cited, but was deterred from presenting himself at Rome by the warnings of Peter Martyr and of Cardinal Contarini. After some hesitation he escaped across the Alps to Geneva. He was cordially received by Calvin, and within two years published six volumes of

Prediche (Eng. trans., Ipswich, 1548), tracts rather than sermons, explaining and vindicating his change of religion. He was minister of the Italian Protestant congregation at Augsburg from 1545 until 1547, when the city was occupied by the imperial forces in the Schmalkaldic War. Escaping by way of Strasbourg he found an asylum in England, where he was made a prebendary of Canterbury, received a pension from Edward VI.'s privy purse, and composed his chief work, *A Trajedy or Dialogue of the unjust usurped Primacy of the Bishop of Rome* (1549), originally written in Latin, but extant only in the translation of John Ponet, bishop of Winchester. The conception of the *Trajedy* bears a remarkable resemblance to that of *Paradise Lost;* and it is almost certain that Milton, whose sympathies with the Italian Reformation were so strong, must have been acquainted with it, and with some of Ochino's later works. In the *Labyrinth* (dedicated to Queen Elizabeth), he assailed the Calvinistic doctrine of predestination.

The accession of Mary in 1553 drove him from England, and he became pastor of the Italian congregation at Zürich. In 1563 the publication of his *Thirty Dialogues,* in one of which his adversaries maintained that he had justified polygamy under colour of a pretended refutation, led to his banishment. He found refuge in Poland until the edict of the 6th of August, 1564, banished all foreign dissidents. He died at Schlakau in Moravia, about the end of 1564.

See *Life* by B. O. Benrath (2nd ed., Brunswick, 1892; Eng. trans. by Helen Zimmern, 1876).

OCHRES, which vary in colour from pale yellow to deep red, brown and violet, and are native earths coloured with hydrated iron oxide, are of two kinds—one having a clayey basis, while the other is a chalky earth; the former variety is in general the richer and purer in colour of the two. Both kinds are widely distributed in beds or pockets, mainly in stratified rocks and rubble and rarely as extensive deposits. Some ochres require only grinding, whereas other varieties require calcination whereby the original colour is modified. In this process the associated earth exercises a marked influence, clayey ochres developing red and violet tints, while chalky varieties take brownish-red and dark brown hues. The well-known ochre, Terra di Siena, which in its native state is a dull-coloured earth, assumes when burnt a fine warm mahogany-brown hue highly valued by artists. Ochres containing much organic matter are sometimes calcined to improve their drying properties in varnish or oil. Ochres are also artificially prepared in large quantities—Mars yellow is either a pure hydrated ferric oxide or an intimate mixture of that substance with an argillaceous or calcareous base, and such compounds by careful calcination can be transformed into Mars orange, violet or red, all reliable pigments. *See* PAINTS, CHEMISTRY OF.

OCHRIDA (Serbo-Croatian *Ohrid*), a city of South Serbia, Yugoslavia, on Lake Ochrida, occupied by axis troops in 1941. Pop. (1931), 9,776, mainly Albanians, with some Serbs and Bulgars. The lake, 2,260 ft. above sea level, with an area of 107 sq.mi. and a maximum depth of 938 ft., lies amid magnificent scenery and is famous for its salmon trout. Malaria is prevalent. Ochrida occupies the site of the ancient *Lychnidos,* which was added to the Macedonian empire by Philip II. (382–336 B.C.) and destroyed by the Bulgars in A.D. 861. The Bulgarian tsar, Samuel, made Ochrida his capital, but was expelled, and in 1014 his empire was conquered by the Greek emperor Basil II. The see of Ochrida was founded by St. Clement in 916, and during the Bulgarian occupation their patriarchate was established here. In 1459 the Serbian patriarchate being suppressed, the administration of the Church was transferred to Ochrida. In 1890 a Bulgarian bishop was appointed to the see, which then became a centre of Bulgarian propaganda.

OCHS, ADOLPH SIMON (1858–1935), American newspaper publisher, was born in Cincinnati, O., on March 12, 1858, of well educated Jewish parents who had emigrated in their youth to the United States from Bavaria. The father, Julius Ochs, was an officer of the United States forces in the Mexican War of 1848, and the Civil War, 1861–65. In 1865 the family settled in Knoxville, Tenn., where Adolph while still a boy attending primary schools delivered newspapers. At the age of 14, he became a printer's devil on the *Knoxville Chronicle.* In 1875–76 he was employed as a compositor by the Louisville, Kentucky, *Courier-Journal.* In 1877 he assisted in establishing the *Chattanooga Dispatch,* and in 1878, at the age of 20, with little or no capital, he gained control of the *Chattanooga Times,* at that time a decrepit newspaper. Assuming at the same time the duties of publisher, editor and business manager, he soon placed the *Chattanooga Times* on a firm basis, and brought it to a leading position among newspapers throughout the South.

In 1896 he acquired the controlling ownership of the *New York Times,* which had long been one of the leading newspapers in the United States, but was then in financial difficulties after 30 years of prosperity. Mr. Ochs then formed the New York Times Company. With a ripe experience in all departments of newspaper making, he steadily strengthened the paper's journalistic and financial position, and resuscitated it from a bankrupt newspaper with less than 10,000 bona fide circulation, to a newspaper with national reputation, a net paid sale (1934) of 466,000 copies on weekdays and 730,000 on Sundays, and from 2,000,000 to 20,000,000 agate lines of advertising annually. Times Square, New York, was named after the Times Building, which was erected in 1905.

Meantime, in 1901, Ochs became proprietor of the *Philadelphia Times,* which he merged with the *Public Ledger* and sold to Cyrus H. K. Curtis in 1912. He was a founder of the Southern Associated Press and later an organizer of the Publishers' Association of the City of New York. From 1900 to his death in 1935 he was a director of the Associated Press.

The influence of Ochs upon newspaper publishing in the United States has been very marked and highly beneficial. Entering New York publishing when the so-called "yellow journalism" was at its height, and in competition with half a dozen of the richest and most powerful newspapers in America, he boldly adopted the slogan, "All the News That's Fit To Print," and devoted his paper not to sensations, but to giving intelligent readers a daily news report, trustworthy, complete, non-partisan and decent.

In a few years Ochs made *The Times* the outstanding example of enterprise in news gathering and ultimately the most widely read newspaper in the United States. In its reporting of the news *The Times* identified itself with pioneers and explorers in various fields—Marconi, Peary, Lindbergh, Byrd (North and South Pole and trans-Atlantic flights), Amundsen, Ellsworth, Scott, Shackleton and others. In its expression of opinion, *The Times* was and remains essentially independent, its editorial position being best described by Ochs himself as intended "to reflect the best informed thought of the country, honest in every line, more than courteous and fair to those who may sincerely differ from its views."

Steadily withstanding the temptation to print a "comic" section and other features detached from the news of the day, Ochs was a pioneer in many newspaper innovations, among which were the introduction in newspapers of rotogravure printing of news pictures, a book review supplement and an open forum for letters to the editor, with the widest latitude for the presentation of opinions in conflict with the editorial views of *The Times.* He was also a pioneer in the adoption of standards to improve newspaper advertising typography, and of standards of advertising designed to exclude all false and misleading material.

Following these principles, he made *The New York Times* "the newspaper of record," publishing the only complete American newspaper index and printing an edition on rag paper for libraries, offices, institutions and those who preserve records. His interest in making accurate source material available to the public was shown in another manner when, with The New York Times Company, he underwrote in 1925, at a cost of over $500,000, the preparation of the manuscript of the *Dictionary of American Biography* by the Learned Societies of America.

In 1918 the trustees of Columbia University in New York awarded *The Times* the first Pulitzer Gold Medal in Journalism

for Meritorious Public Service. In 1922 Ochs was made an honorary Master of Arts by Yale university.

In subsequent years he received honorary doctorates from Columbia university, New York university, Dartmouth and Lincoln university.

He was also awarded the French Legion of Honour and in 1927 received the gold medal of the National Institute of Social Sciences for his services in promoting and maintaining high standards of journalism.

No honour gratified Ochs, however, more than that which came to him in 1928.

In that year of 1928, the community in which he had made his humble start conferred on him the title of "Citizen Emeritus of Chattanooga."

For the story of *The New York Times* see *History of The New York Times* by Elmer Davis (1921) and *Seventy-fifth Anniversary Supplement of The New York Times*, published Sept. 18, 1926. For the history of the *Chattanooga Times* see *Chattanooga Times Jubilee Issue*, July 1, 1928. (L. Wi.)

OCHTERLONY, SIR DAVID, Bart. (1758–1825), British general, was born at Boston, Mass., U.S.A., on Feb. 12, 1758, and went to India as a cadet in 1777. He served under Lord Lake in the battles of Koil, Aligarh and Delhi, and was appointed resident at Delhi in 1803. In 1804, having been promoted to the rank of major general, he defended the city with a very inadequate force against an attack by Holkar. He served in the Nepal War, which he brought to a successful conclusion. Afterward he obtained the signature of the treaty of Segauli (1816), which dictated the subsequent relations of the British with Nepal. For this success Ochterlony was created G.C.B., the first time that honour had been conferred on an officer of the Indian army. In the Pindari War (1817–18) he was equally successful. He was appointed resident in Rajputana in 1818, with which the residency at Delhi was subsequently combined. When Durjan Sal revolted in 1825 against Balwant Singh, the infant raja of Bharatpur, Ochterlony, acting on his own responsibility, supported the raja by proclamation and ordered out a force to support him. Lord Amherst, however, repudiated these proceedings. Ochterlony, who was bitterly chagrined by this rebuff, resigned his office and retired to Delhi. He died at Meerut on July 15, 1825. The Ochterlony column at Calcutta commemorates his death.

See Major Ross of Bladensburg, *The Marquess of Hastings* (Oxford, 1893).

OCHTMANN, LEONARD (1854–1934), American painter, was born in Zonnemaire, Zeeland, the Netherlands, on Oct. 21, 1854. His family removed to Albany, N.Y., in 1866. In 1882 he began to exhibit landscapes at the National academy, and he became a National Academician in 1904. His most characteristic pictures, which recall the work of Inness, are scenes on Long Island sound and on the Mianus river.

OCKLEY, SIMON (1678–1720), English orientalist, was born at Exeter in 1678. He was educated at Queen's college, Cambridge, became fellow of Jesus college and vicar of Swavesey, and in 1711 was made professor of Arabic at Cambridge. The pecuniary embarrassments of his later days form the subject of a chapter in D'Israeli's *Calamities of Authors*. The preface to the second volume of his *History of the Saracens* is dated from Cambridge castle, where he was imprisoned for debt. Ockley maintained that a knowledge of oriental literature was essential to the proper study of theology, and in the preface to his first book, the *Introductio ad linguas orientales* (1706), he urges the importance of the study. In 1707 he published a translation of Leon Modena's *History of the Present Jews throughout the World;* and in 1708 *The Improvement of Human Reason, exhibited in the Life of Hai Ebn Yokdhan.* His chief work is *The History of the Saracens* (1708–18), of which a third volume was published posthumously in 1757. Unfortunately Ockley took as his main authority a ms. in the Bodleian of the pseudo-Wakidi's *Futuh al-Sham,* which is rather historical romance than history. He also translated from the Arabic the *Second Book of Esdras* and the *Sentences of Ali.* Ockley died at Swavesey, Aug. 9, 1720.

O'CLERY, MICHAEL (1575–1643), Irish chronicler, grandson of a chief of the sept of O'Clery in Donegal, was born at Kilbarrow on Donegal bay, and was baptized Tadhg (or "poet"), but took the name of Michael when he became a Franciscan friar. He had already gained a reputation as a student of Irish history and literature, when he entered the Irish college of St. Anthony at Louvain. In 1620, through the initiative of Hugh Boy Macanward (1580–1635), warden of the college, and himself a famous Irish historian and poet, and one of an old family of hereditary bards in Tyrconnell, he began to collect Irish manuscripts and to transcribe everything he could find of historical importance; he was assisted by other Irish scholars, and the results were his *Reim Rioghroidhe* (Royal List) in 1630, *Leabhar Gabhala* (Book of Invasions) in 1631, and his most famous work, called by John Colgan (d. 1659), the Irish biographer, the "Annals of the Four Masters" (1636). Subsequently he produced his *Martyrologium* of Irish saints, based on various ancient manuscripts, an Irish glossary and other works. He lived in poverty, and died at Louvain.

O'CONNELL, DANIEL (1775–1847), Irish statesman, known as "the Liberator," was born on Aug. 6, 1775, near Cahirciveen, a small town in Kerry. He was sprung from a race the heads of which had been Celtic chiefs, had lost their lands in the wars of Ireland, and had felt the full weight of the harsh penal code which long held the Catholic Irish down. His ancestors in the 18th century had sent recruits to the famous brigade of Irish exiles in the service of France, and those who remained at home either lived as tenants on the possessions of which they had once been lords, or gradually made money by smuggling. While a boy he was adopted by his uncle, Maurice O'Connell of Derrynane, and sent to a school at Queenstown, and then to the colleges of St. Omer and Douai in France.

In 1798 O'Connell was called to the bar of Ireland, where he came rapidly to the front. In examining witnesses, he had no rival at the Irish bar. He was, however, a thorough lawyer besides, inferior in scientific learning to two or three of his most conspicuous rivals, but well read in every department of law, and especially a master in all that relates to criminal and constitutional jurisprudence; as an advocate, too, he stood in the very highest rank.

From early manhood O'Connell had turned his mind to the condition of Ireland and the mass of her people. The worst severities of the penal code had been, in a certain measure, relaxed, but the Catholics were still in a state of vassalage, and they were still pariahs compared with the Protestants. The rebellion of 1798 and the union had dashed the hopes of the Catholic leaders, and their prospects of success seemed very remote when, in the first years of the 19th century, the still unknown lawyer took up their cause. Up to this juncture the question had been in the hands of Grattan and other Protestants, and of a small knot of Catholic nobles and prelates; but they aimed only at a kind of compromise, which, while conceding their principal claims, would have placed their church in subjection to the state. O'Connell gave the Catholic movement an energy it had not before possessed. He formed the bold design of combining the Irish Catholic millions, under the superintendence of the native priesthood, into a vast league against the existing order, and of wresting the concession of the Catholic claims from every opposing party in the state by continuous agitation, embracing almost the whole of the people, but maintained within constitutional limits, though menacing and shaking the frame of society. The Catholic Association, at first small, but slowly assuming larger proportions, was formed; attempts of the government and of the local authorities to put its branches down were skilfully baffled by legal devices of many kinds; and at last, after a conflict of years, all Catholic Ireland was arrayed in a powerful organization. O'Connell stood at the head of this great national movement which, controlled from first to last by himself and the priesthood, was essentially conservative in character. His election for Clare in 1828 proved the forerunner of the inevitable change, and the Catholic claims were granted the next year.

O'Connell joined the Whigs on entering parliament, and gave effective aid to the cause of reform. The agitation, however, on the Catholic question had quickened the sense of the wrongs of

Ireland, and the Irish Catholics were engaged ere long in a crusade against tithes and the established church, the most offensive symbols of their inferiority in the state. It may be questioned whether O'Connell was not rather led than a leader in this; the movement, at least, passed beyond his control, and the country for many months was terrorized. Lord Grey proposed measures of repression which O'Connell opposed with extreme vehemence. This caused a breach between him and the Whigs; but he gradually returned to his allegiance to them when they practically abolished Irish tithes, cut down the revenues of the established church and endeavoured to secularize the surplus. In the British house of commons O'Connell stood in the front rank as a debater; and his oratory, massive and strong in argument, made a powerful impression. O'Connell steadily supported Lord Melbourne's government, gave it valuable aid in its general measures, and repeatedly expressed his cordial approval of its policy in advancing Irish Catholics to places of trust and power in the state, though personally he refused a high judicial office. He sincerely advocated the rights of conscience, the emancipation of the slave and freedom of trade. But his rooted aversion to the democratic theories imported from France grew stronger with advancing age. His conservatism was most apparent in his tenacious regard for the claims of property. He actually opposed the Irish Poor law, as encouraging a communistic spirit; he declared a movement against rent a crime, though he advocated a reform of the precarious tenure enjoyed by the Irish peasant.

O'Connell changed his policy as regards Ireland when Sir Robert Peel became minister in 1841. He declared that a Tory régime in his country was incompatible with good government, and he began an agitation for the repeal of the union. He had denounced the union in early manhood as an obstacle to the Catholic cause; he had spoken against the measure in parliament; he believed that the claims of Ireland were set aside or slighted in what he deemed an alien assembly; and, though he had ceased for some years to demand repeal, and regarded it as rather a means than an end, he was throughout life an avowed repealer. In his judgment the repeal of the union would not weaken the real bond between Great Britain and Ireland. The Catholic association of 1828–29 was recreated for the new project. Enormous meetings convened by the priesthood, and directed or controlled by O'Connell, assembled in 1842–43, and probably nine-tenths of the Irish Catholics were unanimous in the cry for repeal. O'Connell seems to have thought success certain; but he had not perceived the essential difference between his earlier agitation and this. The enlightened opinion of the three kingdoms for the most part approved the Catholic claims, and as certainly it condemned repeal. After some hesitation Peel resolved to put down the repeal movement. A vast intended meeting was proclaimed unlawful, and in Oct. 1843 O'Connell was arrested and held to bail, with 10 or 12 of his principal followers. He was convicted (Feb. 1844) after the trials that followed, but the judges were biased, and the sentence of imprisonment for a year and a fine of £2,000 was reversed on a writ of error by the house of lords (Sept. 1844), and he and his colleagues were again free. The spell, however, of O'Connell's power had vanished; his health had suffered much from a short confinement; he was verging upon his seventieth year; and he was disturbed by the growth of a party in the repeal ranks who scoffed at his views, and advocated the revolutionary doctrines which he had always feared and abhorred. Before long famine had fallen on the land, and under this visitation the repeal movement, already paralyzed, collapsed. O'Connell died on May 15, 1847, at Genoa, while on his way to Rome. His body was brought back to Dublin and buried in Glasnevin cemetery.

Catholic Ireland calls O'Connell its "Liberator" still; he possessed the wisdom, the caution and the tact of a real statesman. But the battle in which he fought was not to be won in his generation. O'Connell married in 1802 his cousin Mary O'Connell, by whom he had three daughters and four sons, Maurice, Morgan, John (1810–1858), known as the "Young Liberator," and Daniel, all of whom sat in parliament.

BIBLIOGRAPHY.—His son John's *Life* (1846) and *Recollections and Experiences* (1849), the biographies by W. Fagan (1847), M. F. Cusack (1872), J. O'Rourke and O'Keefe (1875), and J. A. Hamilton (1888); also R. Dunlop, *Daniel O'Connell and the Revival of National Life in Ireland* (1900), R. Houston, *Daniel O'Connell: his Early Life and Journal, 1795–1802* (1906), and A Zimmermann, *Daniel O'Connell der Befreier und seine politische Bedeutung für Irland und England* (Paderborn, 1909).

O'CONNOR, FEARGUS EDWARD (1794–1855), Chartist leader, was the son of the Irish Nationalist politician Roger O'Connor. He entered parliament as M.P. for Cork and a follower of Daniel O'Connell in 1832; but three years later the "Liberator" had him unseated, by petition, for his indiscipline. He turned to radical agitation in England and on the publication of the Charter in 1838 became one of the best-known Chartist leaders. Owing to his rough humour, his energy and his invective he became their most popular speaker, and the circulation of his journal, the *Northern Star,* outstripped all others. He advocated physical force, generally, however, with the proviso that moral force must be tried first, and at the Chartist convention of 1839 acquiesced in William Lovett's "moral force" leadership. Although not concerned in the insurrection of 1839 he was imprisoned for a year upon another charge. In 1841 he reorganized the movement by the foundation of the National Charter association, and attained a position of such power that he was able practically to expel or silence Lovett and all others who advocated compromise with the middle class. But though he raised Chartism to its greatest power he was unable to direct it to victory. He permitted the general strike of 1842; in the midst of it his fears overcame him and he condemned it, securing its immediate defeat. After this fiasco he diverted Chartist energies to the support of his land company scheme for settling town workers on small holdings. For a while this appeared successful, and a first settlement, named O'Connorville, was opened at Herringsgate, Bucks. He was also elected M.P. for Nottingham in 1847. Next year, however, the company was found to be bankrupt, and the ignominious collapse of the revolutionary agitation of that year, to which he had pinned his hopes, made O'Connor's behaviour, already eccentric, plainly maniacal. He was, very belatedly, declared insane in 1852 and died in 1855. His funeral procession, 50,000 strong to Kensal Green, may be regarded as the last Chartist demonstration.

O'Connor was a tall, loud-voiced, handsome man, of unlimited devotion and energy and great oratorical powers; he was, however, vacillating, excessively vain, jealous and of small intellectual powers. (*See* CHARTISM.) (R. W. P.)

OCONOMOWOC, a city of Waukesha county, Wis., U.S., on federal highway 16; 33 mi. W. of Milwaukee; served by the Chicago, Milwaukee, St. Paul and Pacific railway. Pop. (1950) 5,345.

Oconomowac is located in a region of lakes. The city was founded about 1837 and incorporated in 1875. Its name is an Indian word said to mean "home of the beaver."

O'CONOR, CHARLES (1804–1884), U.S. lawyer, was born in New York city on Jan. 22, 1804. He was admitted to the bar in 1824. From 1853 to 1854 he was United States district attorney for New York. After the Civil War he became senior counsel for Jefferson Davis on his indictment for treason, and was one of his bondsmen. He took a prominent part in the prosecution of William M. Tweed and members of the "Tweed Ring" and published *Peculation Triumphant, Being the Record of a Five Years' Campaign against Official Malversation, A.D. 1871–1875* (1875).

O'Conor moved to Nantucket, Mass., in 1881, and died there on May 12, 1884.

OCONTO, a city of northeastern Wisconsin, U.S.A., on the W. shore of Green bay (Lake Michigan) at the mouth of the Oconto river; the county seat of Oconto county. It is on federal highway 41, and is served by the Chicago and North Western and the Chicago, Milwaukee, St. Paul and Pacific railways. Pop. (1950) 5,055. It has a large fishing industry and several manufacturing plants. It was founded in 1846 and chartered in 1882.

OCORONAN, a small group of tribes of South American Indians, provisionally regarded as constituting an independent linguistic stock. The Ocoronas live or lived in eastern Bolivia along the upper Mamore river, at the missions of San Ignacio,

BY COURTESY OF UFA

OCTOPUS OR DEVIL FISH

This underwater photograph of an octopus shows the animal crawling on the bottom supported by three of its eight arms. The arms are sucker bearing and are used in capturing crustaceans, the animal's chief food, which have been previously paralyzed with a poison secreted by its salivary glands. Octopods also feed on bivalve molluscs and fishes

San Martin and Santa Rosa de Moxos. Apart from brief references to them by the early missionaries, little is known concerning their culture. Rivet believes that the Ocoronas are merely a sub-group of the Chapacuran (*q.v.*) stock.

See G. de Crequi-Montfort and P. Rivet, "La Famille linguistique Capakura" (*J. Soc. Américanistes de Paris* [n.s.] vol. x., pp. 119–173).

OCOTILLO (*Fouquieria splendens*), a North American shrub of the candle-wood family (Fouquieriaceae), called also coachwhip, Jacob's-staff and vine-cactus. It is a characteristic shrub of rocky deserts from western Texas to southern California and southward in Mexico. Near the base the stem divides into several slender, erect, furrowed, intensely spiny branches, usually from 8 to 20 ft. high. It bears small rounded leaves, the midribs of which harden into the spines, and showy bright-scarlet flowers in terminal clusters. The ocotillo is sometimes grown as a hedge plant; in Mexico the branches are woven into fences.

OCTAHEDRON: *see* SOLIDS, GEOMETRIC.

OCTAVE, a period or series of eight members. In ecclesiastical usage the octave is the eighth day after a particular church festival, the feast day itself and the "octave" being counted. The octave thus always falls on the same day of the week as the festival, and any event occurring during the period is said to be "in the octave." In music, an octave is the eighth full tone above or below any given note. It is produced by double or half the number of vibrations corresponding to the given note. In the interval between a note and its octave is contained the full scale, the octave of a note forming the starting-point of another scale of similar intervals to the first. The interval between a note and its octave is also called an octave. The name is also applied to an open metal stop in an organ, and to a flute (more usually known as the piccolo) one octave higher in pitch than the regular flute. It is also a term for a "parade" in fencing. The "law of octaves" was a term applied in 1865 to a relationship among the chemical elements enunciated by J. A. R. Newlands.

In literature an octave is a form of verse consisting of eight iambic lines, and complete in itself. From its use by the poets of Sicily, the form is usually called the Sicilian octave. It is distinguished from a single stanza of *ottava rima* by having only two rhymes, arranged *abababab*. In German literature the octave has been used not infrequently since 1820, when Ruckert published "Sicilianen," as they are called in German, for the first time. The word is often used to describe the eight opening lines of a sonnet.

OCTAVIA, the name of two princesses of the Augustan house. (1) Octavia, daughter of Gaius Octavius and sister of the emperor Augustus, was the wife of Gaius Marcellus, one of the bitterest enemies of Julius Caesar. In 41 B.C. her husband died, and she was married to Marcus Antonius, with the idea of bringing about a reconciliation between him and her brother. Her efforts were at first successful, but in 36 Antony left for the Parthian War and renewed his intrigue with Cleopatra. Though Octavia took out troops and money to him (35), he refused to see her and formally divorced her in 32. (2) OCTAVIA, daughter of the emperor Claudius, was the wife of Nero, by whom she was put to death. A Latin tragedy on her fate is attributed, though wrongly, to Seneca.

OCTOBER, the eighth month of the old Roman year, which began in March. In the Julian calendar, while retaining its old name, it became the tenth month, and had 31 days assigned to it. Several attempts were made to rename the month in honour of the emperors. Thus it was in succession temporarily known as Germanicus, Antoninus, and Herculeus, the last a surname of Commodus. The senate's attempt to christen it Faustinus in honour of Faustina, wife of Antoninus, was equally unsuccessful. By the Slavs it is called "yellow month," from the fading of the leaf; to the Anglo-Saxons it was known as Winterfylleth, because at this full moon (*fylleth*) winter was supposed to begin.

OCTOPUS, the name given in zoology to a single genus of eight-armed Cephalopoda (*q.v.*), one of whose distinguishing characters is the presence of two rows of suckers on each arm. As a less strictly defined term the name may be given to all the eight-armed Cephalopoda, of which some 36 genera have been described (*e.g., Eledone, Cirroteuthis, Argonauta*). The genus *Octopus* is a large one containing upwards of 140 species. Its representatives occur in nearly all seas (though it is poorly represented in Arctic and Antarctic waters) and some are found at great depths. *Octopus vulgaris* is found on British coasts (principally in the south), but it has a limited distribution in these waters, and is not often taken, the allied *Eledone cirrosa* being more common.

The sucker-bearing arms, strong jaws and sinister appearance of these animals have conferred on them a name for ferocity which is not undeserved. The stories of their attacks on man are sufficiently well attested, though they are often exaggerated.

The octopus moves about by means of its arms on the sea bottom, and is not habitually free-swimming, though like other Cephalopods, it can propel itself through the water by means of the funnel (*see* CEPHALOPODA). *Octopus* and the related genus *Eledone* live on the sea-bottom and are mainly found in shallow coastal water. According to Lo Bianco the common octopus in the Gulf of Naples prefers rocky situations for its lair during its early years. Certain forms (*e.g., Benthoctopus*) are found in very deep water, the greatest depth from which a member of the genus *Octopus* has been obtained being 1,875 fathoms. Other Octopods, however, are inhabitants of the open sea and are found swimming or floating at the surface (*Argonauta*) or at greater depths (*Eledonella, Cirroteuthis*). A species of *Eledonella* has been taken at a depth of 2,900 fathoms. Those which live permanently in very deep water are usually highly modified, having gelatinous tissues, large medusiform webs and reduced gills and dentition.

The common octopus feeds principally on crabs. Lo Bianco has shown that before killing its victims it paralyses them with a poison secreted by its salivary glands. The same observer has recorded that the common octopus in captivity will devour its own arms even if it is amply supplied with its normal food. Certain species of octopus attain a considerable size. The common octopus, *O. vulgaris,* sometimes spans over six feet with its arms and the giant *O. apollyon* of the western coast of the United States has been known to have a diameter of 28 feet.

Most species of this genus lay eggs in grapelike clusters. Lee states that the female *O. vulgaris* broods over the clusters, holding them in the membranous expansion of its arms and syringing them with jets of water from its funnel (*see* CEPHALOPODA).

Octopods are eaten fresh or dried by the natives of many parts of the world. The flesh of young *O. vulgaris* is still considered a delicacy in Naples.

It has been mentioned above that the true octopus (*Octopus vulgaris*) is usually rare on the English coast. In 1899 and 1900, however, they became so abundant on the south coast as to attract general notice, and to constitute a veritable plague.

OCTOSTYLE, in architecture, a portico with eight columns or a building with such a portico in front; *e.g.,* Parthenon at Athens.

OCTROI, an indirect or consumption tax levied by a local political unit, normally the commune or municipal authority, on certain categories of goods on their entry into its area (Fr. *octroyer,* from Low Lat. *auctorizare,* to confer, authorize, empower; *i.e.,* in this relation, the empowering of the subordinate political unit to impose certain taxation within its precincts; hence by extension the taxation system itself). The institution of such tax in Italy goes back to Roman times, when it bore the title of *portorium,* and in France to the 13th century. Suppressed in the latter country under the Revolution in 1791, the tax was re-established five years after; and until the close of the first quarter of the 20th century was operative very generally throughout the land. It was abolished in Belgium in 1870 and in Egypt in 1903; after World War II it still persisted in France, Italy, Spain, Portugal and Austria, but a marked tendency toward radical reduction in its total area of operation, or even its general suppression, had long been manifest.

France provides an outstanding example of this evolution. Pub-

lic opinion in that country—critical for generations of a tax system highly irksome, inconvenient in its mode of collection and unduly costly in relation to its yield (the levy process sometimes absorbed 50%)—was turned decisively against the system by the phenomenal increase of motor traffic: from 108,000 passenger cars in 1913 to 1,300,000 in 1932 and from 80,000 commercial vehicles in 1920 to 435,000 in 1932 (by the beginning of 1948 there were 1,650,000 vehicles circulating on the roads of France).

Commodities that might be subjected to this tax in France were prescribed by law and were divided into the following six classes: (1) liquids (artificial gaseous drinks, nonalcoholic beverages; vinegar; vegetable oils); (2) foods (meats, poultry, game, fish, butter, eggs, cheese, jams, fruits, etc.); (3) fuel (wood, coal, coke, candles, mineral oil, etc.); (4) fodder (fresh oil cakes, dog biscuits, etc.); (5) building materials (plaster, lime, stone, bricks, slates, metals, sanitary appliances, woods, glass, etc.); and (6) miscellaneous (soaps, polishes, varnishes, paints, etc.). For all the separate commodities within these six groups maximum rates of tariff were promulgated by presidential decree, specific rates being fixed for the three (until the law of Jan. 1941, six) separate sorts of octroi area, established on the basis of population, namely, communes having (1) less than 10,000 inhabitants, (2) from 10,000 to 50,000 and (3) more than 50,000. The maximum rates applicable in 1945 in these three groups were fixed as follows: for meat at 30 fr., 40 fr. and 50 fr., for butter at 24 fr., 40 fr. and 60 fr. and for coal at 0.90 fr., 1.50 fr. and 2 fr. per 100 kg. respectively.

The Paris octroi yielded from 200,000,000 fr. to 250,000,000 fr. yearly in the 1920s, nearly 600,000,000 fr. in 1938 but only 314,000,000 fr. in 1942, the shrinkage being caused mainly by the nonarrival of supplies in the area. As from Aug. 1943 the tax was suppressed for the city and for the 60 suburban communes. Important provincial towns (*e.g.,* Lyons, Bordeaux, Clermont-Ferrand, Troyes, Perpignan, etc.) had abolished the system many years before World War II. In May 1945 only 200 octroi areas, holding a total population of less than 1,000,000, were still existing in France; there had been 1,491 in 1918 and approximately 1,050 (with a total population of 14,500,000) in 1926.

The tax was finally suppressed from Jan. 1, 1949, because of the excessive formalities and the cost of its collection and control.

See M. Tardit and A. Ripert, *Traité des octrois municipaux* (Paris, 1904); L. Hourcade, *Manuel encyclopédique des contributions indirectes des octrois* (Poitiers, 1925).

O'CURRY, EUGENE (1796–1862), Irish scholar, was born at Dunaha, county Clare, in 1796, the son of a farmer who was a man of unusual intelligence. After being employed for some time in the topographical and historical section of the Irish ordnance survey, O'Curry earned his living by translating and copying Irish manuscripts. The catalogue of Irish manuscripts in the British Museum was compiled by him. On the founding of the Roman Catholic University of Ireland (1854) he was appointed professor of Irish history and archaeology. His lectures were published by the university in 1860. Three other volumes of lectures were published posthumously, under the title *On the Manners and Customs of the Ancient Irish* (1873). His voluminous transcripts, notably eight huge volumes of ancient Irish law, testify to his unremitting industry.

O'Curry died in Dublin in 1862.

ODAENATHUS or ODENATUS (Gr. *'Οδαίναθος*, "palm," אחינר , "little ear"), the Latinized form of ODAINATH, the name of a famous prince of Palmyra in the second half of the 3rd century A.D. who succeeded in recovering the Roman east from the Persians and restoring it to the empire. He belonged to the leading family of Palmyra, which bore, in token of Roman citizenship, the *gentilicium* of Septimius; hence his full name was Septimius Odainath. It is practically certain that he was the son of Septimius Hairan, the "senator and chief of Tadmor," the son of Septimius Odainath, "the senator."

The year when he became chief of Palmyra is not known, but already in an inscription dated A.D. 258 he is styled *vir consularis, i.e.,* of consular rank. He possessed the characteristic vigour and astuteness of the old Arab stock from which he sprang; and in his wife, the renowned Zenobia (*q.v.*), he found an able supporter of his policy.

The defeat and captivity of the emperor Valerian (A.D. 260) left the eastern provinces largely at the mercy of the Persians; the prospect of Persian supremacy was not one which Palmyra or its prince had any reason to desire. At first, it seems, Odainath attempted to propitiate the Persian monarch Shapur (Sapor) I; but when his gifts were contemptuously rejected he decided to throw in his lot with the cause of Rome. Odainath initiated that active policy which, while it added to his own fame, in a short time brought his native city to its ruin. He fell upon the victorious Persians who were returning home after the sack of Antioch, and before they could cross the Euphrates inflicted upon them a considerable defeat.

Then, when two usurping emperors were proclaimed in the east (A.D. 261), Odainath took the side of Gallienus the son and successor of Valerian, attacked and put to death the usurper Quietus at Emesa (Homs), and was rewarded for his loyalty by the grant of an exceptional position (A.D. 262).

Odainath may have assumed the title of king before; but he now became *corrector totius Orientis,* not indeed joint ruler, nor Augustus, but "independent lieutenant of the emperor for the East" (Theodor Mommsen, *Provinces,* ii, p. 103)[1]. In a series of rapid and successful campaigns, during which Odainath left Palmyra under the charge of Septimius Worod, his deputy, he crossed the Euphrates and relieved Edessa, recovered Nisibis and Carrhae and even took the offensive against the power of Persia and twice invested Ctesiphon, the capital, itself; probably also he brought back Armenia into the empire.

These brilliant successes restored the Roman rule in the east; and Gallienus did not disdain to hold a triumph with the captives and trophies which Odainath had won (A.D. 264).

While observing all due formalities toward his overlord, there can be little doubt that Odainath aimed at independent empire; but during his lifetime no breach with Rome occurred. He was about to start for Cappadocia against the Goths when he was assassinated, together with Herodes his eldest son, by his nephew Maeonius; there is no reason to suppose that this deed of violence was instigated from Rome.

After his death (A.D. 266–267) Zenobia succeeded to his position, and practically governed Palmyra on behalf of her young son Wahab-allath or Athenodorus. (*See* PALMYRA.)

(G. A. C.; X.)

ODDFELLOWS, ORDER OF, a secret benevolent and social society and, subsequently, a friendly benefit society also, having mystic signs of recognition, initiatory rites and ceremonies and various grades of dignity and honour. Great antiquity has been claimed for the order of Oddfellows, but the members themselves now generally admit that the institution cannot be traced back beyond the first half of the 18th century and explain the name as adopted at a time when the severance into sects and classes was so wide that persons aiming at social union and mutual help were a marked exception to the general rule. Mention is made by Defoe of the society of Oddfellows, but the oldest lodge of which the name has been handed down is the Loyal Aristarcus, no. 9, which met in 1745 "at the Oakley Arms, Borough of Southwark; Globe Tavern, Hatton Garden; or the Boar's Head in Smithfield, as the noble master may direct." The earliest lodges were supported by each member and visitor paying a penny to the secretary on entering the lodge, and special sums were voted to any brother in need. If out of work he was supplied with a card and funds to reach the next lodge, and he went from lodge to lodge until he found employment. The lodges gradually adopted a definite common ritual and became confederated under the name of the Patriotic Order. Toward the end of the century many of the lodges were broken up by state prosecutions on the suspicion that

[1] The Roman chronicler Trebellius Pollio goes further and asserts "Odenatus rex Palmyrenorum optinuit totius Orientis imperium. . . . Gallienus Odenatum participato imperio Augustum vocavit," *Hist. Aug.,* xxiii, 10 and 12. This is not borne out by the evidence. The highest rank claimed for him by his own people is recorded in an inscription dated 271 (Cooke, *North Semitic Inscrs.,* no. 130) set up by the two generals of the Palmyrene army; Odainath is styled "king of kings and restorer of the whole city"; but this does not mean that he ever held the title of Augustus, and the inscription was set up after his death and during the revolt of Palmyra.

their purposes were "seditious," but the society continued to exist as the Union Order of Oddfellows until 1809. In 1813, at a convention in Manchester, was formed the Independent Order of Oddfellows, Manchester Unity, which now overshadows all the minor societies in England. Oddfellowship was introduced into the United States from the Manchester Unity in 1819, and the grand lodge of Maryland and the United States was constituted on Feb. 22, 1821. It now rivals in membership and influence the Manchester Unity, from which it severed its connection in 1842. In 1843 it issued a dispensation for opening the Prince of Wales Lodge No. 1, at Montreal, Canada. The American society, including Canada and the United States, has its headquarters at Baltimore. Organizations connected either with the United States or England have been founded in France, Germany, Switzerland, Denmark, The Netherlands, Norway, Sweden, Poland, Czechoslovakia, the British dominions and elsewhere.

The most complete and trustworthy account of the institution is that in *The Complete Manual of Oddfellowship, its History, Principles, Ceremonies and Symbolism*, privately printed (1879). (*See* also FRIENDLY SOCIETIES.)

ODE, a form of stately and elaborate lyrical verse. The original signification of an ode was a chant, a poem arranged to be sung to an instrumental accompaniment. There were two great divisions of the Greek *melos* or song. One of them, in the hands of Alcaeus, Anacreon and Sappho, came close to what modern criticism knows as lyric. On the other hand, the choir-song, in which the poet spoke for himself, but always supported, or interpreted, by a chorus, led up to what is known as ode proper. It was Alcman who first gave to his poems a strophic arrangement, and the strophe (*q.v.*) has come to be essential to an ode. Stesichorus, Ibycus and Simonides of Ceos led the way to the two great masters of ode among the ancients, Pindar and Bacchylides. The form and verse-arrangement of Pindar's great lyrics have regulated the type of the heroic ode. It is now perceived that they are consciously composed in very elaborate measures. So far from being, as critics long supposed, utterly irregular, they are more like the *canzos* and *sirventes* of the mediaeval troubadours than any modern verse. The Latins lost the secret of these complicated harmonies, and made no serious attempt to imitate the odes of Pindar. The ode, as it was practised by the Romans, returned to the lyrical form of Sappho and Alcaeus. This was exemplified, in the most exquisite way, by Horace and Catullus.

The earliest modern writer to perceive the value of the antique ode was Ronsard, who attempted to recover the fire and volume of Pindar; his principal experiments date from 1550 to 1552. The poets of the Pléiade recognized in the ode one of the forms of verse with which French prosody should be enriched, but in their use of Greek words crudely introduced, and in their quantitative experiments, they offended the genius of the French language. The ode died in France almost as rapidly as it had come to life. Early in the 19th century the form was resumed, and we have the *Odes* composed between 1817 and 1824 by Victor Hugo, the odes of Lamartine, those of Victor de Laprade (collected in 1844), and the *Odes funambulesques* of Théodore de Banville (1857).

The earliest odes in English, using the word in its strict form, were the *Epithalamium* and *Prothalamium* of Spenser. Ben Jonson introduced a kind of elaborate lyric to which he gave the name of ode; and some of his disciples, in particular Randolph, Cartwright and Herrick, followed him. The "Hymn on the Morning of Christ's Nativity," begun by Milton in 1629, may be considered an ode, and his lyrics "On Time" and "At a Solemn Music" belong to the same category. But it was Cowley who introduced into English poetry the ode consciously built up, on a solemn theme and as definitely as possible on the ancient Greek pattern. He was no more perspicacious than others, however, in observing what the rules were which Pindar had followed. He published his "Pindaric" odes in 1656. These shapeless pieces became very popular after the Restoration, and enjoyed the sanction of Dryden in three or four irregular odes which are the best of their kind in the English language. In 1705 Congreve published a *Discourse on the Pindarique Ode*, and he wrote odes, in strophe, antistrophe and epode, which were the earliest of their kind in English; unhappily they were not very poetical. The attempts of Gilbert West (1703–56) to explain the prosody of Pindar (1749) inspired Gray to write his "Progress of Poesy" (1754) and "The Bard" (1756). Collins, meanwhile, had in 1747 published a collection of odes devised in the Aeolian or Lesbian manner. The odes of Wordsworth, Coleridge and Tennyson are entirely irregular. Shelley desired to revive the pure manner of the Greeks, but he understood the principle of the form so little that he began his "Ode to Naples" with two epodes, passed on to two strophes, and then indulged in four successive antistrophes. Coventry Patmore, in 1868, printed a volume of irregular *Odes*. Swinburne, although some of his odes, like those of Keats, are really elaborate lyrics, written in a succession of stanzas identical in form, cultivated the Greek form also, and some of his political odes follow very closely the type of Bacchylides and Pindar. Neither Sir William Watson nor Laurence Binyon, each of whom wrote memorable odes, adopted the Pindaric form.

See Philipp August Böckh, *De metris Pindari* (1811); Wilhelm Christ, *Metrik der Griechen und Römer* (1874); Edmund Gosse, *English Odes* (1881).

ODENKIRCHEN, former German town, 21 mi. by rail S.W. of Düsseldorf, and at the junction of lines to Munich, Gladbach and Stolberg. Pop. was 19,194. Odenkirchen became a town in 1856 and united with Gladbach-Rheydt in 1929. It carried on cotton spinning and weaving, tanning and dyeing.

ODENSE, a city of Denmark, the chief town of the *amt* (county) of its name, which forms the northern part of the island of Fyn (Fünen). Pop. (1950) 100,940. Odense, or Odinsey, originally Odinsoe, *i.e.*, Odin's island, is one of the oldest cities of Denmark. St. Canute's shrine was a great resort of pilgrims throughout the middle ages. In the 16th century the town was the meeting-place of several parliaments, and down to 1805 it was the seat of the provincial assembly of Fyn. The city lies 4 mi. from Odense fjord on the Odense Aa, the main portion on the north side of the stream, and the industrial Albani quarter on the south side. It has a station on the railway route between Copenhagen and Jutland and Schleswig-Holstein via Korsør. A canal, 15½ ft. to 21 ft. deep, gives access to the town from the fjord. St. Canute's cathedral is one of the largest and finest buildings of its kind in Denmark. It is constructed of brick in a pure Gothic style. Originally dating from 1081–93, it was rebuilt in the 13th century. Under the altar lies Canute (Knud), the patron saint of Denmark, who intended to dispute with William of Normandy the possession of England, but was slain in an insurrection at Odense in 1086; Kings John and Christian II. are also buried within the walls. Our Lady's church, built in the 13th century and restored in 1851–52 and again in 1864, contains a carved altar-piece (16th century) by Claus Berg of Lübeck. Odense castle was erected by Frederick IV., who died there in 1730. Exports, mostly agricultural produce (butter, bacon, eggs); imports, iron, petroleum, coal, yarn and timber.

ODENWALD, a wooded mountain region of Germany, almost entirely in Hessen, with small portions in Bavaria and Württemberg-Baden. It stretches between the Neckar and the Main, and is 50 mi. long by 20 to 30 broad. Its highest points are the Katzenbuckel (2,054 ft.), the Neunkircher Höhe (1,985 ft.) and the Krähenberg (1,965 ft.). The wooded heights overlooking the Bergstrasse are studded with castles and mediaeval ruins.

ODER (Lat. *Viadua;* Slavonic *Vjodr*), a European river, 550 mi. long, which rises in the Odergebirge (Lower Carboniferous rocks of the Bohemian massif). After flowing southeast it quickly turns northeast and after a short distance northwest enters upon the Silesian plain, which general direction it maintains across the recent deposits of the lowlands in a wide valley and with low banks. In its lower course it frequently bifurcates, forming many islands, and its main channel passes Stettin into the Grosses Haff, which is connected with the Baltic sea by three arms, the Peene, Swine and Dievenov forming the islands of Usedom and Wollin. The Swine in the middle is the main channel for navigation.

Rising in Czechoslovakia it touches the Upper Silesian coalfield

and enters Germany above Ratibor, after forming the frontier between Germany and Poland from Bohumin. It receives a number of left-bank tributaries from the gneisses and granites of the Bohemian massif, the chief being the Glatzer Neisse, Katzbach, Bober and Lausitzer Neisse, but the biggest affluents are those on the right-bank, the Warthe with its tributaries the Netze (Notéc) and the Obra, the Malapane and Bartsch, all of which rise in Poland. The most important towns on the river banks are Ratibor, Oppeln, Brieg, Breslau, Glogau, Frankfort-on-Oder, Küstrin, Stettin and Swinemünde. The river forms an important highway into eastern Germany, Poland and Czechoslovakia. It is utilized by three main currents of traffic, traffic between Stettin and Berlin, goods transported to or from the mining area of Upper Silesia (this traffic was reduced by the partition of Upper Silesia between Germany and Poland) and the traffic to and from Poland by the Warthe and its connections. The river begins to be navigable for barges at Ratibor, when it is about 100 ft. wide, and for larger vessels at Breslau where constant dredging is always necessary. Several parts of the main stream have been canalized, especially in the low-lying reaches, in its upper courses and between Stettin and the sea. It is now possible for sea-going vessels, drawing 24 ft. of water to reach Stettin. In addition navigation is possible on the Warthe, Netze and Obra, and the river is connected by canals with the Vistula, the Havel and the Spree.

By the Treaty of Versailles (1919) Poland extended her territory westwards to include the province of Posen (Posnania) but, although the boundary nowhere touches the Oder, long portions of its right-bank are now in Poland. The treaty also declared international the Oder and all navigable portions of its system which provide natural access to the sea for more than one State, and also appointed a commission consisting of three representatives of Prussia, and one each of Poland, Czechoslovakia, Great Britain, France, Denmark and Sweden to prepare an Act of Navigation. The work of this commission was by no means easy, for unforeseen difficulties arose upon the question of the right of the commission to legislate for the upper reaches of the Warthe, the Netze and the Old Netze.

ODESSA, a seaport of the Ukrainian S.S.R., in 46° 29′ N., 30° 44′ E., on the southern shore of a semi-circular bay, at the north-west angle of the Black sea. Pop. (1939) 604,223. It has five harbours; the Quarantine, New Harbour, Pratique and Cabotage harbours are sheltered by two breakwaters, 4,020 ft. and 2,120 ft. in length. The Petroleum harbour is sheltered by a breakwater 840 ft. in length. There is very good anchorage in the inner roads and a floating crane with a capacity of 40 tons. There are two patent slips and a double-sided floating dock, lifting power 4,800 tons. The harbours freeze for a few days in each year, and the bay occasionally freezes. Navigation is interrupted on an average for 16 days per annum, though the powerful ice breaker now installed lessens this time. The climate is influenced by its proximity to the steppe, and is continental. Average January temperature 23·2° F, July 72·8° F, average rainfall 14 in. per annum. The exports are mainly grain, linseed, wool, cattle, sugar and timber, and the imports coal, naphtha, iron, machinery, agricultural implements, raw cotton, tobacco, manufactured goods and tea, coffee and other colonial goods. Coal cargoes are discharged in the new harbour, several travelling steam cranes being fitted for the purpose. The Cabotage harbour is reserved for Russian coasting vessels. A repairing yard with a pontoon and fitting out basin is situated near the petroleum harbour. Improvements to the port are now being carried out, with a view to providing quayside and berths for 21 steamers, with warehouses and railway lines along the quay.

The town is picturesquely situated on a plateau 150 ft. above sea-level, which is intersected by ravines and forms the limit of the steppe region. The climate is milder than that of the rest of the Ukraine and in the vicinity of Odessa are numerous health resorts along the *limans*. In these limans, or former river mouths now cut off from the sea by the silting up of the rivers, are waters containing concentrated salt solutions, with high proportions of magnesium and calcium salts, iodine and bromine. Their mud is strongly impregnated with sulphuretted hydrogen and is highly beneficial to sufferers from rheumatism, nervous disorders and skin diseases. Spring gives the environs of Odessa a brief glory of brightly coloured blossoms but summer heat and drought soon parch the vegetation. The broad streets of the town have been planted with trees, peculiarly grateful in the brief intense heat of summer and in contrast with the general treeless condition of the surrounding steppe. The population is exceedingly mixed even for a seaport, and includes Great Russians, Ukrainians, Jews, Poles, Germans, Greeks, Armenians, Tatars and Turks, among others.

History.—The bay of Odessa has had a chequered history; it was colonised by Greeks at a very early period, but their ports Istrianorum Portus, Isiacorum Portus and Odessus at the mouth of the Tiligul liman disappeared in the 3rd and 4th centuries.

In spite of its favoured position between the Dniester and the Dnieper estuaries, no further settlements were made until the 14th century, when a Tatar chief Khaji Beg or Bey founded a fort on the present site of Odessa. Olgerd, prince of Lithuania, captured the fort in 1396 and it remained alternately in the power of Lithuania and Poland until its capture by Tatars in the 16th century. During the whole of this period it continued to be an important export centre for grain, salt and fish. The Turks captured it from the Tatars in the 16th century and built a fortress Yeni-Dunia to protect the harbour. In 1774 during the Russo-Turkish War, the Russians captured the town, but returned it to the Turks, finally occupying it and the whole territory between the Dniester and the Bug in 1789. A French captain, de Ribas, who had led the Russians in their assault on the town, was afterwards entrusted with the planning, in consultation with the French engineer Voland, of a military and commercial port, and a finely laid out Russian city replaced the former Turco-Tatar settlement.

In 1803 Odessa became the chief town of a separate municipal captaincy under Armand, duc de Richelieu, who developed its trade and importance. In 1824 it became the seat of the governors of Novorossia (New Russia) and Bessarabia and, as a free port, became very prosperous. Railway communication with Kiev and Kharkov and with Jassy in Rumania was established in 1866. The free port was closed in 1859. The town successfully resisted a Turkish attack in 1876–77. A numerous floating population began to be attracted, abundant work being available in years of good harvest, but unemployment became rife in years of bad harvest. In the 1905 revolution the workers, supported by the insurrectionary battleship "Potemkin," of the Black sea fleet, took active part in the revolutionary movement. The rising was suppressed, but broke out with renewed vigour in October of the same year and was again suppressed.

After the overthrow of the Kerensky government in October 1917, the Ukrainian Rada (Petlura) occupied the town. In January 1918 the Bolshevik workers of the town, aided by troops from the former Rumanian front and from the Black sea fleet expelled the followers of Petlura and proclaimed a soviet republic. In mid-March German and Austro-Hungarian troops occupied the town, and later the Ukrainian government, installed under German protection, called in the Entente troops, who occupied the greater part of the town. The French fleet bombarded the wretched inhabitants and French, Serbian, Polish and later Greek troops were landed. Eventually, however, a second soviet government was set up in April 1919, but was overthrown by General Denikin in August 1919. In February 1920 the soviet finally captured the town.

During this disastrous period a third of the houses were destroyed and numbers of the population were killed, while others fled into the surrounding villages. During 1921 and 1922 famine and famine diseases further devastated the town and lack of fuel caused the inhabitants to pull down many wooden buildings. But in 1923 conditions became somewhat easier and since then trade has slowly returned. Another difficulty, however, faced the town. Formerly much of its trade came via the Dniester river and Akkerman (now Cetatea Alba) from Bessarabia and in the absence of diplomatic relations between Rumania and Russia, a state of

armed neutrality existed on that river and trade was practically nonexistent. However, in spite of all these adverse conditions, the population in 1926 had reached normal size, increasing in 1937 to 534,000 and in 1939 to 604,223, thus showing an increase of about 40% as compared with 1926. The city gradually returned to normal conditions and trade and shipping were flourishing, making Odessa the principal seaport and commercial centre on the Black sea.

In the course of World War II Odessa played a very considerable role. The enormous strategic and economic importance of Odessa, not only for the Ukraine but for the entire U.S.S.R., made it quite necessary for the invading Germans to take possession of it in the shortest possible time in order to secure their flank and to use it as a basis for expansion over the Ukrainian industrial and mining area and the North Caucasian region. Besieged by the German and Rumanian troops Odessa fell after a gallant defense on Oct. 16, 1941, and was liberated only in the course of the great German retreat in 1943–44.

Industry.—In addition to its trading, port and shipbuilding activities Odessa has numerous industrial enterprises, among which the production of salt takes an important place. There are also glass, metal and brick works and factories for producing machinery, especially for agricultural purposes, and munitions, superphosphates, tin, cork, glue and oil from oleaginous seeds are produced. Recently introduced industries are the manufacture of cinematograph apparatus, of water gauges, of twine and of preserved foods. There is also an aeroplane factory and a regular air service has been established between Odessa and Kharkov, with intermediate stations at Poltavo and Zinovievsk. The water supply of the town is obtained from the Dniester river. The town has several theatres and museums. The former University of South Russia has been converted into a Technical institute, and there are Medical and Agricultural institutes, a State Public library and a Jewish Academical library. The medley of languages has encouraged the use of Esperanto and there is an Esperanto institute.

There is a zoological garden, laid out chiefly for purposes of acclimatization, and animals destined for the more severe conditions of the north are kept there for some time. The Bacteriological station was the first of its kind in Russia.

ODESSA, a town in west central Texas, U.S., and the county seat of Ector county. It is about 110 mi. N.W. of San Angelo at the junction of U.S. highway 80 and state highway 51, and is served by the Texas and Pacific railroad and by air lines and buses. The altitude is 2,890 ft. and the mean annual temperature 63°. The population was 29,495 in 1950; it was 9,573 in 1940, of whom 9,038 were native white; and 2,407 according to the census of 1930.

Odessa is an important retail and shipping centre for petroleum and livestock. It is also one of the largest U.S. producers of oil well supplies such as derricks and welding equipment. There are chemical plants, brass and iron works, oil wells and a large carbon black plant constructed in 1944. Other products include explosives, pressure vessels, tool boxes, mattresses, furniture, bottles, concrete and tile. Agricultural pursuits are limited chiefly to stock raising.

The town is regulated by a manager-council form of government chosen in direct nonpartisan elections for two-year terms. The sewage treatment plant and waterworks are municipally owned and operated and the total property valuation of Odessa was assessed at $26,866,080 in 1950. There are two hospitals of which the oldest was established in 1933.

Odessa is set against a background of desert plains and oil country. It was settled by Methodists in 1881. Of geological interest is the Odessa meteor crater, ten miles to the southwest, which is said to be the second largest in the U.S. It is about 600 ft. in diameter, is composed of iron, and was located by surveyors as being 164 ft. below the earth's surface.

ODIN or **OTHIN,** the chief god of the northern pantheon, is represented as an old man with one eye. Frigg is his wife, Thor and Balder, among other gods, are his sons. He is also said to have been the father of several legendary kings. His exploits and adventures are a common theme in the poetic and prose Eddas. Here his character is distinguished rather by wisdom than martial prowess, and reference is frequently made to his skill in poetry and magic. In *Ynglinga Saga* he is represented as reigning in Sweden. In notices relating to religious observances Odin appears chiefly as the giver of victory or as the god of the dead. He receives the souls of the slain, who in his palace, Valhalla (*q.v.*), live a life of fighting and feasting, similar to that which has been their desire on earth. Human sacrifices were frequently offered to Odin, especially prisoners taken in battle. In the poem *Hávamál* the god himself is represented as sacrificed. The worship of Odin seems to have prevailed chiefly, if not solely, in military circles. To the Anglo-Saxons he was known as Woden (*q.v.*) and to the Germans as Wodan (Wuotan). Owing to the peculiar character of this god and the prominent position which he occupies, the mythology of the north presents a striking contrast to that of Greece. *See* Teutonic Peoples, *ad fin.;* and Woden.

ODO or Eudes (d. 898), king of the Franks, a son of Robert the Strong, count of Anjou (d. 866), is sometimes referred to as duke of France and also as count of Paris. For his resistance to the attacks of the Normans Odo was chosen king by the western Franks when the emperor Charles the Fat was deposed in 887, and was crowned at Compiègne in February 888. He defeated the Normans at Montfaucon and elsewhere, but was soon involved in a struggle with powerful nobles, who supported the claim of Charles, afterwards King Charles III, to the Frankish kingdom. To gain support Odo owned himself a vassal of the German king, Arnulf, but in 894 Arnulf declared for Charles. Eventually, after a struggle of three years, Odo was compelled to come to terms with his rival, and to surrender to him a district north of the Seine. He died at La Fère on Jan. 1, 898.

See E. Lavisse, *Histoire de France,* vol. ii (1903); and E. Favre, *Eudes, comte de Paris et roi de France* (1893).

ODO or Eudes (d. *c.* 736), king, or duke, of Aquitaine, obtained this dignity about 715, and his territory included the southwestern part of Gaul from the Loire to the Pyrenees. In 718 he appears as the ally of Chilperic II, king of Neustria, who was fighting against the Austrasian mayor of the palace, Charles Martel; but after the defeat of Chilperic at Soissons in 719 he probably made peace with Charles by surrendering to him the Neustrian king and his treasures. Odo was also obliged to fight the Saracens who invaded the southern part of his kingdom, and inflicted a severe defeat upon them at Toulouse in 721. When, however, he was again attacked by Charles Martel, the Saracens renewed their ravages, and Odo was defeated near Bordeaux; he was compelled to crave protection from Charles, who took up this struggle and gained his momentous victory at Poitiers in 732. In 735 the king abdicated, and was succeeded by his son Hunold.

ODOACER or Odovacar (*c.* 434–493), the first barbarian ruler of Italy, son of Aedico or Idico, was born in the district bordering on the middle Danube about the year 434. He was probably one of the tribe of Scyrri who had invaded Pannonia about 430. It is said that as a tall young recruit for the Roman armies, dressed in a sordid vesture of skins, on his way to Italy, he entered the cell of St. Severinus, to ask his blessing. The saint had an inward premonition of his future greatness, and in blessing him said, "Fare onward into Italy. Thou who art now clothed in vile raiment wilt soon give precious gifts unto many."

Odoacer was probably about 30 years of age when he thus entered the imperial service. By the year 472 he had risen to some eminence. In the year 475 the emperor Nepos was driven into exile, and the successful rebel Orestes was enabled to array in the purple his son, a handsome boy of 14 or 15, who was named Romulus after his grandfather, and nicknamed Augustulus, from his inability to play the part of the great Augustus. Before this puppet emperor had been a year on the throne the barbarian mercenaries rose in mutiny, demanding to be made proprietors of one-third of the soil of Italy. To this request Orestes returned a peremptory negative. Odoacer now offered his fellow-soldiers to obtain for them all that they desired if they would seat him on the throne. On Aug. 23, 476, he was proclaimed king; five days later Orestes was made prisoner at Placentia and beheaded. Augustulus was compelled to descend from the throne, but his

life was spared.

Odoacer was 42 years of age when he thus became chief ruler of Italy, and he reigned 13 years with undisputed sway. The administration was conducted as much as possible on the lines of the old imperial government. The settlement of the barbarian soldiers on the lands of Italy probably affected the great landowners rather than the labouring class. To the herd or *coloni* and *servi* it probably made little difference whether the master whom they served called himself Roman or Rugian.

In 477 or 478 the dethroned emperor Nepos sent ambassadors to Zeno, emperor of the east, begging his aid in the reconquest of Italy. These ambassadors met a deputation from the Roman senate, sent nominally by the command of Augustulus, really no doubt by that of Odoacer, to declare that they did not need a separate emperor. The senate had chosen Odoacer, and they therefore prayed Zeno to confer upon him the dignity of patrician, and entrust the "diocese" of Italy to his care. Zeno returned a harsh answer to the senate, requiring them to return to their allegiance to Nepos. In fact, however, he did nothing for the fallen emperor, but accepted the new order of things, and even addressed Odoacer as patrician. On the other hand, the latter sent the ornaments of empire to Constantinople as an acknowledgment of the fact that he did not claim supreme power. Information as to the actual title assumed by the new ruler is somewhat confused. He does not appear to have called himself king of Italy, but only king of the tribes of barbarians that followed him. By the Roman inhabitants of Italy he was addressed as "dominus noster," but his right to exercise power would in their eyes rest, in theory, on his recognition as patricius by the Byzantine Augustus. At the same time he marked his own high pretensions by assuming the prefix Flavius. His internal administration was probably, upon the whole, wise and moderate, and he may be looked upon as a not altogether unworthy predecessor of Theodoric.

In the history of the papacy Odoacer figures as the author of a decree promulgated at the election of Felix II in 483, forbidding the pope to alienate any of the lands or ornaments of the Roman Church, and threatening any pope who should infringe this edict with anathema.

The chief events in the foreign policy of Odoacer were his Dalmatian and Rugian wars. In the year 480 the ex-emperor Nepos, who ruled Dalmatia, was traitorously assassinated in Diocletian's palace at Spalato by the counts Viator and Ovida. In the following year Odoacer invaded Dalmatia, slew the murderer Ovida, and reannexed Dalmatia to the western state. In 487 he appeared as an invader in his own native Danubian lands. War broke out between him and Feletheus, king of the Rugians. Odoacer entered the Rugian territory, and defeated and captured Feletheus. In the following year Frederick, son of the captive king, endeavoured to raise again the fallen fortunes of his house, but was defeated by Onulf, brother of Odoacer, and took refuge at the court of Theodoric the Ostrogoth.

This Rugian war was probably an indirect cause of the fall of Odoacer. His increasing power rendered him too formidable to the Byzantine court. At the same time, Zeno was embarrassed by the formidable neighbourhood of Theodoric the Ostrogoth. In these circumstances arose the plan of Theodoric's invasion of Italy, the details of which belong properly to the life of Theodoric. It is sufficient to state here that he entered Italy in August 489, defeated Odoacer at the Isontius (Isonzo) on the 28th of August, and at Verona on the 30th of September. Odoacer then shut himself up in Ravenna, and there maintained himself for four years, with one brief gleam of success, during which he emerged from his hiding place and fought the battle of the Addua (Aug. 11, 490), in which he was again defeated. A sally from Ravenna (July 10, 491) was again the occasion of a murderous defeat. At length, the famine in Ravenna having become almost intolerable, and the Goths despairing of ever taking the city by assault, negotiations were opened for a compromise (Feb. 25, 493). It was stipulated that Ravenna should be surrendered, that Odoacer's life should be spared, and that he and Theodoric should be recognized as joint rulers of the Roman state. The arrangement was evidently a precarious one, and was soon terminated by the treachery of Theodoric. He invited his rival to a banquet in the palace of the Lauretum on the 15th of March, and there slew him with his own hand. "Where is God?" cried Odoacer when he perceived the ambush into which he had fallen. "Thus didst thou deal with my kinsman," shouted Theodoric, and clove his rival with the broadsword from shoulder to flank. Thelan, his son, was not long after put to death by order of the conqueror. Thus perished the whole race of Odoacer.

Bibliography.—The chief authorities for the life of Odoacer are the so-called "Anonymus Valesii," generally printed at the end of Ammianus Marcellinus; the *Life of Severinus*, by Eugippius; the chroniclers, Cassiodorus and "Cuspiniani Anonymus" (both in Roncalli's collection); and the Byzantine historians, Malchus and John of Antioch. A fragment of the latter historian, unknown when Gibbon wrote, is to be found in the fifth volume of Müller's *Fragmenta Historicorum Graecorum*. There is a thorough investigation of the history of Odoacer in R. Pallmann's *Geschichte der Völkerwanderung*, vol. ii (Weimar, 1864). *See* also T. Hodgkin, *Italy and Her Invaders*, vol. iii (Oxford, 1885).

ODOFREDUS, Italian jurist of the 13th century. He was born at Bologna and studied law under Balduinus and Accursius. After having practised as an advocate both in Italy and France, he became professor at Bologna in 1228. The commentaries on Roman law attributed to him are valuable as showing the growth of the study of law in Italy, and for their biographical details of the jurists of the 12th and 13th centuries. Odofredus died at Bologna on Dec. 3, 1265.

Over his name appeared *Lecturae in codicem* (Lyons, 1480), *Lecturae in digestum vetus* (Paris, 1504), *Summa de libellis formandis* (Strasbourg, 1510), *Lecturae in tres libros* (Venice, 1514) and *Lecturae in digestum novum* (Lyons, 1552).

ODONATA, an order of insects (*q.v.*) comprising the dragonflies and damselflies (*see* Dragonfly).

O'DONNELL, the name of an ancient and powerful Irish family, lords of Tyrconnel in early times, and the chief rivals of the O'Neills in Ulster. Like the family of O'Neill (*q.v.*), that of O'Donnell was descended from Niall of the Nine Hostages, king of Ireland at the beginning of the 5th century; the O'Neills, or Cinel Owen, tracing their pedigree to Owen (Eoghan), and the O'Donnells, or Cinel Connell, to Conall Gulban, both sons of Niall. Tyrconnel, the district named after the Cinel Connell, where the O'Donnells held sway, comprised the greater part of the modern county of Donegal except the peninsula of Inishowen; and since it lay conterminous with the territory ruled by the O'Neills of Tyrone, who were continually attempting to assert their supremacy over it, the history of the O'Donnells is for the most part a record of tribal warfare with their powerful neighbours, and of their own efforts to make good their claims to the overlordship of northern Connaught.

The first chieftain of mark in the family was Goffraidh (Godfrey), son of Donnell Mor O'Donnell (d. 1241). Goffraidh, who was "inaugurated" as "The O'Donnell," *i.e.*, chief of the clan, in 1248, successfully raided Tyrone and Connaught, and was severely wounded in the battle of Roscede (1257). In the following year he defeated Brian O'Neill, but died soon after from his old wounds. He was succeeded in the chieftainship by his brother Donnell Oge.

In the 16th century, when the English began to make determined efforts to bring the whole of Ireland under subjection to the crown, the O'Donnells of Tyrconnel played a leading part, co-operating at times with the English, especially when such co-operation appeared to promise triumph over their ancient enemies the O'Neills, at other times joining with the latter against the English authorities.

Manus O'Donnell (d. 1564), son of Hugh Dubh O'Donnell, was left to rule Tyrconnel during his father's pilgrimage to Rome about 1511; and retained the chief authority when Hugh Dubh returned. A family quarrel ensued, but with the help of the O'Neills, Manus established his hold over Tyrconnel. In 1522, however, the O'Neills and O'Donnells were again at war. Conn Bacach O'Neill, 1st earl of Tyrone, determined to subjugate the O'Donnells. Supported by several septs of Munster and Connaught, and assisted by English contingents and the MacDonnells

of Antrim, O'Neill took the castle of Ballyshannon, and after devastating a large part of Tyrconnel encamped at Knockavoe, near Strabane. Here he was surprised at night by Hugh Dubh and Manus O'Donnell, and severely defeated. The war continued, however, and in 1531 O'Donnell applied to the English government for protection, giving assurances of allegiance to Henry VIII. In 1537 Lord Thomas Fitzgerald and his five uncles were executed for rebellion in Munster, and the English government made every effort to lay hands also on Gerald, the youthful heir to the earldom of Kildare, a boy of 12 years of age who was in the secret custody of his aunt Lady Eleanor McCarthy. This lady, in order to secure a powerful protector for the boy, accepted an offer of marriage by Manus O'Donnell, who on the death of Hugh Dubh in July 1537 was inaugurated The O'Donnell. Conn O'Neill was a relative of Gerald Fitzgerald, and this event accordingly led to the formation of the Geraldine League, a federation which combined the O'Neills, the O'Donnells, the O'Briens of Thomond, and other powerful clans; the primary object of which was to restore Gerald to the earldom of Kildare, but which afterwards aimed at the complete overthrow of English rule in Ireland. In Aug. 1539 Manus O'Donnell and Conn O'Neill were heavily defeated by the lord deputy at Lake Bellahoe, in Monaghan.

In the west Manus continued to assert the supremacy of the O'Donnells in north Connaught, where he compelled O'Conor Sligo to acknowledge his overlordship in 1539. In 1542 he went to England and presented himself, together with Conn O'Neill and other Irish chiefs, before Henry VIII. In his later years Manus was harassed by his son Calvagh, who imprisoned him in 1555, and deposed him from all authority in Tyrconnel. He died in 1564. Manus O'Donnell is also described by the Four Masters as "a learned man, skilled in many arts, gifted with a profound intellect, and the knowledge of every science." At his castle of Portnatrynod near Strabane he supervised if he did not actually dictate the writing of the *Life of Saint Columbkille* in Irish, which is preserved in the Bodleian library at Oxford. Manus was several times married. His first wife, Joan O'Reilly, was the mother of Calvagh, and two daughters, both of whom married O'Neills; the younger, Margaret, was wife of the famous rebel Shane O'Neill. His second wife, Hugh's mother, by whom he was ancester of the earls of Tyrconnel (*see* below), was Judith, sister of Conn Bacach O'Neill, 1st earl of Tyrone, and aunt of Shane O'Neill. He died in 1564.

CALVAGH O'DONNELL (d. 1566), eldest son of Manus O'Donnell, in the course of his above-mentioned quarrel with his father and his half-brother Hugh, sought aid in Scotland from the MacDonnells, who assisted him in deposing Manus and securing the lordship of Tyrconnel. Hugh then appealed to Shane O'Neill, who invaded Tyrconnel at the head of a large army in 1557 to secure supremacy over Ulster, and encamped on the shore of Lough Swilly. Calvagh surprised the O'Neills in their camp at night and routed them. Calvagh was then recognized by the English government as lord of Tyrconnel; but in 1561 he and his wife were captured by Shane O'Neill in the monastery of Kildonnell. His wife, Catherine Maclean, who had previously been the wife of the earl of Argyll, was kept by Shane O'Neill as his mistress and bore him several children, though grossly ill-treated by her savage captor; Calvagh himself was subjected to atrocious torture during the three years that he remained O'Neill's prisoner. He was released in 1564 on conditions which he had no intention of fulfilling; and crossing to England he appealed to Queen Elizabeth. In 1566 Sir Henry Sidney marched to Tyrconnel, and restored Calvagh to his rights. Calvagh, however, died in the same year, and as his son Conn was a prisoner in the hands of Shane O'Neill, his half-brother Hugh MacManus was inaugurated The O'Donnell in his place. Hugh, who in the family feud with Calvagh had allied himself with O'Neill, now turned round and combined with the English to crush the hereditary enemy of his family; and in 1567 he utterly routed Shane at Letterkenny, compelling him to seek refuge with the MacDonnells of Antrim, by whom he was put to death. In 1592 Hugh abdicated in favour of his son Hugh Roe O'Donnell (*see* below); but Niall Garve, second son of Calvagh's son Conn, resented the passing of the chieftainship to the descendants of Manus O'Donnell's second marriage. His elder brother was Hugh of Ramelton, whose son John, an officer in the Spanish army, was father of Hugh Baldearg O'Donnell (d. 1704), known in Spain as Count O'Donnell, who commanded an Irish regiment as brigadier in the Spanish service. This officer came to Ireland in 1690 and raised an army in Ulster to be used in the service of James II, afterwards deserting to the side of William III, from whom he subsequently accepted a pension.

NIALL GARVE O'DONNELL (1569–1626), grandson of Calvagh, made terms with the English government, to whom he rendered valuable service both against the O'Neills and against his cousin. But in 1601 he quarrelled with the lord deputy, who, though willing to establish Niall Garve in the lordship of Tyrconnel, would not permit him to enforce his supremacy over Cahir O'Dogherty in Inishowen. Charged with complicity in Cahir O'Dogherty's rebellion in 1608, Niall Garve was sent to the Tower of London, where he remained till his death in 1626. He married his cousin Nuala, the sister of Hugh Roe and Rory O'Donnell. When Rory fled with the earl of Tyrone to Rome in 1607, Nuala, who had deserted her husband when he joined the English against her brother, accompanied him, taking with her her daughter Grania. She was the subject of an Irish poem, of which an English version was written by James Mangan from a prose translation by Eugene O'Curry.

HUGH ROE O'DONNELL (1572–1602), eldest son of Hugh MacManus O'Donnell, and grandson of Manus O'Donnell by his second marriage with Judith O'Neill, was the most celebrated member of his clan. His mother was Ineen Dubh, daughter of James MacDonnell of Kintyre; his sister, the second wife of Hugh O'Neill, 2nd earl of Tyrone. These family connections with the Hebridean Scots and with the O'Neills made the lord deputy, Sir John Perrot, afraid of a powerful combination against the English government, and induced him to establish garrisons in Tyrconnel and to demand hostages from Hugh MacManus O'Donnell, which the latter refused to hand over. In 1587 Perrot conceived a plan for kidnapping Hugh Roe (Hugh the Red), now a youth of 15, who had already given proof of exceptional ability. A merchant vessel laden with Spanish wines was sent to Lough Swilly, and Hugh Roe with some youthful companions was enticed on board, when the ship immediately set sail and conveyed the party to Dublin. The boys were kept in prison for more than three years. In 1591 young O'Donnell escaped; and after enduring terrible privations he made his way to Tyrconnel, where in the following year his father handed the chieftainship over to him.

Red Hugh then led an expedition against Turlough Luineach O'Neill, who was at war with his kinsman Hugh, earl of Tyrone, with whom O'Donnell was in alliance, at the same time assuring the lord deputy of his loyalty. Determined to vindicate the traditional claims of his family in north Connaught, he aided Hugh Maguire against the English, though on the advice of Tyrone he abstained for a time from committing himself too far. When, however, in 1594 Enniskillen castle was taken and the women and children flung into the river from its walls by order of Sir Richard Bingham, the English governor of Connaught, O'Donnell sent urgent messages to Tyrone for help; and while he himself hurried to Derry to withstand an invasion of Scots from the isles, Maguire defeated the English with heavy loss at Bellanabriska (The Ford of the Biscuits). In 1595 Red Hugh again invaded Connaught, putting to the sword all above 15 years of age unable to speak Irish; he captured Longford and Sligo, which placed north Connaught at his mercy. In 1596 he agreed in conjunction with Tyrone to a cessation of hostilities with the English, and met the government commissioners near Dundalk.

The terms he demanded were, however, refused. He hoped for help from Philip II of Spain, with whom he and Tyrone had been in correspondence. In the beginning of 1597 he raided Connaught, where O'Conor Sligo had been set up by the English as a counterpoise to O'Donnell. He devastated the country and returned to Tyrconnel with rich spoils; in 1598 he helped to defeat the English at the Yellow Ford on the Blackwater; and

in 1599 he defeated an attempt by the English under Sir Conyers Clifford, governor of Connaught, to succour O'Conor Sligo in Collooney castle, which O'Donnell captured, forcing Sligo to submission. The government now sent Sir Henry Docwra to Derry, and O'Donnell entrusted to his cousin Niall Garve the task of opposing him. Niall Garve, however, went over to the English, making himself master of O'Donnell's fortresses of Lifford and Donegal. While Hugh Roe was besieging Donegal in 1601, he heard that a Spanish force had landed in Munster. He marched rapidly to the south, and was joined by Tyrone at Bandon, but a night attack on the English besieging the Spaniards in Kinsale having utterly failed, O'Donnell, who attributed the disaster to the incapacity of the Spanish commander, took ship to Spain on Jan. 6, 1602, to lay his complaint before Philip III. He was favourably received by the Spanish king, but he died at Simancas on Sept. 10 in the same year.

Rory O'Donnell, 1st earl of Tyrconnel (1575–1608), second son of Hugh MacManus O'Donnell, and younger brother of Hugh Roe, accompanied the latter in the expedition to Kinsale; and when his brother sailed for Spain he transferred his authority as chief to Rory. In 1602 Rory gave in his allegiance to Lord Mountjoy, the lord deputy; and in the following summer he went to London with the earl of Tyrone, when James I created him earl of Tyrconnel. In 1605 he was made the king's lieutenant in Donegal. But the arrangement between Rory and Niall Garve insisted upon by the government displeased both O'Donnells, and Rory, like Hugh Roe before him, entered into negotiations with Spain. His country had been devastated by famine and war, and his own extravagance had plunged him in debt. These circumstances and the fear that his designs were known to the government induced him to leave Ireland. In Sept. 1607 "the flight of the earls" (*see* O'Neill) took place, Tyrconnel and Tyrone reaching Rome in April 1608, where Tyrconnel died on July 28. His wife, the beautiful daughter of the earl of Kildare, was left behind in the haste of Tyrconnel's flight, and lived to marry Nicholas Barnewell, Lord Kingsland. By Tyrconnel she had a son Hugh; and among other children a daughter Mary Stuart O'Donnell, who, born after her father's flight from Ireland, was so named by James I after his mother. This lady, after many romantic adventures, married a man called O'Gallagher and died in poverty on the continent.

Rory O'Donnell was attainted by the Irish parliament in 1614, but his son Hugh, who lived at the Spanish court, assumed the title of earl; and the last titular earl of Tyrconnel was this Hugh's son Hugh Albert, who died without heirs in 1642, and who by his will appointed Hugh Baldearg O'Donnell (*see* above) his heir, thus restoring the chieftainship to the elder branch of the family. To a still elder branch belonged Daniel O'Donnell (1666–1735), a general of the famous Irish brigade in the French service, whose father, Turlough, was a son of Hugh Dubh O'Donnell, elder brother of Manus, son of an earlier Hugh Dubh mentioned above. Daniel served in the French army in the wars of the period, fighting against Marlborough at Oudenarde and Marlplaquet at the head of an O'Donnell regiment. He died in 1735.

The famous Cathach, or Battle-Book of the O'Donnells, was in the possession of General Daniel O'Donnell, from whom it passed to more modern representatives of the family, who presented it to the Royal Irish academy, where it is preserved. This relic, of which a curious legend is told (*see* P. W. Joyce, *A Social History of Ancient Ireland,* 1903, vol. i p. 501), is a Psalter said to have belonged to St. Columba, a kinsman of the O'Donnells, which was carried by them in battle as a charm or talisman to secure victory. Two other circumstances connecting the O'Donnells with ancient Irish literature may be mentioned. The family of O'Clery, to which three of the celebrated "Four Masters" belonged, were hereditary Ollaves (doctors of history, music, law, etc.) attached to the family of O'Donnell; while the "Book of the Dun Cow" (*Lebor-na-h Uidhre*), one of the most ancient Irish mss., was in the possession of the O'Donnells in the 14th century; and the estimation in which it was held at that time is proved by the fact that it was given to the O'Connors of Connaught as ransom for an important prisoner, and was forcibly recovered some years later. *See* O'Neill, and the authorities there cited.

O'DONNELL, LEOPOLD (1809–1867), duke of Tetuan, Spanish general and statesman, was born at Santa Cruz, Teneriffe, on January 12, 1809. General of division in the army of Queen Christina, he accompanied her into exile in 1840; attempted unsuccessfully a rising in her favour at Pamplona in 1841, helped in the overthrow of Espartero (1843) and from 1844–48 served the new government in Cuba. War minister (1854) under Espartero, he plotted successfully against his chief in 1856 and became head of the cabinet from the July revolution until October, and again in July 1858. He took command of the expedition to Morocco (Dec. 1859) and was made duke after the surrender of Tetuan. He resigned office in 1863 until 1865, resumed it and resigned again in favour of Narvaez in 1866. He died at Bayonne, Nov. 5, 1867.

O'DONNELL, PATRICK (1856–1927), cardinal archbishop of Armagh, Ireland, was born of humble parents at Kilraine, Donegal, on Nov. 28, 1856, and was educated locally, then at the Catholic university at Dublin, and finally at Maynooth, where he took priest's orders in 1880. Eight years later he became bishop of Raphoe, a see which he held for 34 years, during which he transformed the diocese set in the wild highlands of Donegal. Dr. O'Donnell was a strong constitutional nationalist and one of the wisest men in the party. Perhaps his supreme gift to Ireland was his sense of the importance of substituting peace for the violent religious hatred prevailing in northern Ireland. He believed in good will for the modification of existing differences due to territorial and religious conditions. He was a member of the Irish convention 1917–18.

In 1923 the pope nominated him coadjutor to Cardinal Logue, archbishop of Armagh, whom he succeeded in the primacy in the following year. In 1925 he received the cardinalate. In 1927 he held a plenary synod of the Irish hierarchy, at which far-reaching reforms were undertaken. The cardinal spoke Gaelic from his childhood and promoted the use of the vernacular. He died on Oct. 22, 1927, at Carlingford.

ODONTOGLOSSUM, a genus of epiphytic plants of the orchid family (Orchidaceae), comprising about 100 species native to the mountains of tropical America. Many species are well known in greenhouse cultivation, including numerous hybrids. *O. grande,* the baby orchid, has showy yellow flowers, barred with cinnamon-brown, 5 in. to 6 in. across. (*See* Orchids.)

ODONTORNITHES, the term proposed by O. C. Marsh for North American fossil birds possessed of teeth (Gr. ὀδούς, tooth, ὄρνις, ὄρνιθος bird), notably the genera *Hesperornis* and *Ichthyornis* from Cretaceous deposits. In 1875 he divided the "subclass" into Odontolcae, with the teeth standing in grooves, and Odontotormae, with the teeth in separate alveoles or sockets. The Odontornithes are now called the Superorder Odontognathae, or the new world toothed birds. (*See* Hesperornis and Ichthyornis).

ODO OF BAYEUX (*c.* 1036–1097), Norman bishop and English earl, was a uterine brother of William the Conqueror, from whom he received, while still a youth, the see of Bayeux (1049). But his active career was that of a warrior and statesman. He found ships for the invasion of England and fought in person at Senlac; in 1067 he became earl of Kent, and for some years he was a trusted royal minister. At times he acted as viceroy in William's absence; at times he led the royal forces to chastise rebellions. But in 1083 he was suddenly disgraced and imprisoned for having planned a military expedition to Italy. He was accused of desiring to make himself pope; more probably he thought of serving as a papal condottiere against the emperor Henry IV. The Conqueror, when on his death-bed, reluctantly permitted Odo's release (1087). The bishop returned to his earldom and soon organized a rebellion with the object of handing over England to his eldest nephew, Duke Robert. William Rufus, to the disgust of his supporters, permitted Odo to leave the kingdom after the collapse of this design (1088), and thenceforward Odo was the right-hand man of Robert in Normandy. He took part in the agitation for the first crusade, and started in the duke's company for Palestine, but died on the way, at Palermo

(Feb. 1097). Little good is recorded of Odo. His vast wealth was gained by extortion and robbery. His ambitions were boundless and his morals lax. But he was a patron of learning and, like most prelates of his age, a great architect. He rebuilt the cathedral of his see, and may perhaps have commissioned the unknown artist of the celebrated Bayeux tapestry.

Odo must be distinguished from two English prelates of the same name and also from an English earl. Odo or Oda (d. 959), archbishop of Canterbury, was bishop of Ramsbury from 927 to 942, and went with King Aethelstan to the battle of Brunanburh in 937. In 942 he succeeded Wulfhelm as archbishop of Canterbury, and he appears to have been an able and conscientious ruler of the see. He had great influence with King Edwy, whom he had crowned in 956. Odo (d. 1200), abbot of Battle, was a monk of Christ church, Canterbury, and was prior of this house at the time when Thomas Becket was murdered. In 1175 he was chosen abbot of Battle, and on two occasions the efforts of Henry II alone prevented him from being elected archbishop of Canterbury. Odo or Odda (d. 1056), a relative of Edward the Confessor, during whose reign he was an earl in the west of England, built the minster at Deerhurst in Gloucestershire.

See the authorities cited for WILLIAM I and WILLIAM II, the biographical sketch in *Gallia Christiana*, xi, 353–360; H. Wharton, *Anglia Sacra*, i, 334–339 (1691); and F. R. Fowke, *The Bayeux Tapestry* (1898). (H. W. C. D.)

ODORIC (*c.* 1286–1331), styled "of Pordenone," one of the chief travellers of the later middle ages, and a *Beatus* of the Roman Church, was born at Villa Nuova, a hamlet near the town of Pordenone in Friuli, in or about 1286. According to the ecclesiastical biographers, in early years he took the vows of the Franciscan order and joined their convent at Udine, the capital of Friuli.

Friar Odoric was despatched to the east, where a remarkable extension of missionary action was then taking place, about 1316–18, and did not return till the end of 1329 or beginning of 1330. He was in western India soon after 1321 (pretty certainly in 1322) and he spent three years in China between the opening of 1323 and the close of 1328. His route to the east lay by Trebizond and Erzerum to Tabriz and Sultanieh, in all of which places the order had houses. From Sultanieh he proceeded by Kashan and Yázd, and turning thence followed a devious route by Persepolis and the Shiraz and Baghdad regions, to the Persian gulf. At Hormuz he embarked for India, landing at Thana, near Bombay. After visiting many parts of India he sailed in a junk to Sumatra, visiting various ports on the northern coast of that island, and thence to Java, to the coast (it would seem) of Borneo, to Champa (South Cochin-China), and to Canton, at that time known to western Asiatics as *Chin-Kalan* or Great China (Mahachin). He travelled extensively in China, and visited Hangchow, then renowned, under the name of *Cansay, Khanzai*, or *Quinsai* (*i.e., Kingsze* or royal residence), as the greatest city in the world, of whose splendours Odoric gives details.

At Peking he remained for three years, attached, no doubt, to one of the churches founded by Archbishop John of Monte Corvino, at this time in extreme old age. Returning overland across Asia, through the Land of Prester John and through Casan, the adventurous traveller seems to have entered Tibet, and even perhaps to have visited Lhasa. He then returned to Venice *via* Persia and Asia Minor. During a part at least of these long journeys the companion of Odoric was Friar James, an Irishman. After his return Odoric went to the Minorite house attached to St. Anthony's at Padua, and there, in May 1330, he related the story of his travels, which was taken down in homely Latin by Friar William of Solagna. Odoric died at Udine on Jan. 14, 1331. The fame of his vast journeys appears to have made a much greater impression on the laity of his native territory than on his Franciscan brethren.

Popular acclamation made him an object of devotion, the municipality erected a noble shrine for his body, and his fame as saint and traveller had spread far and wide before the middle of the century, but it was not till four centuries later (1755) that he was formally beatified. Odoric's credit was not benefited by the liberties which Sir John Mandeville took with it. The substar of that knight's alleged travels in India and Cathay is stolen fr Odoric, though amplified with fables from other sources and fr his own invention, and garnished with his own unusually cle astronomical notions. There are many details in Odoric's narı tive which prove its genuineness.

The best editions of Odoric are by G. Venni, *Elogio storico a gesta del Beato Odorico* (Venice, 1761); H. Yule in *Cathay and t. Way Thither* (1866), vol. i, pp. 1–162, vol. ii, appendix, pp. 1–4 and H. Cordier, *Les Voyages . . . du . . . frère Odoric . . .* (189. (edition of Old French version of *c.* 1350). The edition by T. Domen chelli (Prato, 1881) may also be mentioned; likewise those texts Odoric embedded in the *Storia universale delle Missione Franc scan* iii, 739–781, and in Hakluyt's *Principal Navigations* (1599); ii, 39–6 *See* also John of Viktring (Joannes Victoriensis) in *Fontes reru Germanicarum*, ed. J. F. Boehmer; vol. i, ed. by J. G. Cotta (Stuttgar 1843), p. 391; Wadding, *Annales Minorum*, A.D. 1331, vol. vii, pı 123–126; Bartholomew Albizzi, *Opus conformitatum . . . B. Francis . . .*, bk. i, par. ii, conf. 8 (fol. 124 of Milan ed. of 1513); John o Winterthur in Eccard, *Corpus historicum medii aevi*, vol. i, col 1894–97, especially 1894; C. R. Beazley, *Dawn of Modern Geograph* (1897, etc.), iii, 250–287, 548–549, 554, 565–566, 612–613, etc.

O'DUFFY, EOIN (1892–1944), Irish military leader, wa born on Oct. 30, 1892, near Castleblayney, County Monaghan Eire. He joined Michael Collins' Irish rebels in 1917, but wa captured and imprisoned in Belfast as leader of a rebel division After release, he rejoined Collins in 1921, became chief of staf (1921–22) and then general officer commanding the Irish Free State forces (1924–25). He was also chief commissioner of the Civic guard (1922–23) but was removed from this post by Eamon De Valera. O'Duffy then joined the opposition which he helped weld into the United Ireland party with the avowed purpose of fighting communism; he became its president in 1933. During this period, he also headed the Blue Shirts, a fascist offshoot organization of the U.I. party with a one-time boasted membership of 120,000. O'Duffy, however, was a poor politician and the U.I. disintegrated under his leadership. He himself resigned in 1934. To revive his waning prestige, he recruited 1,400 volunteers who joined Francisco Franco's "holy crusade against bolshevism" in Spain in 1936. But the O'Duffy brigade lost heart after a taste of battle and returned home in disgrace after six months in Spain. With this fiasco, O'Duffy lost what was left of his prestige. He died in Dublin on Nov. 30, 1944.

ODYSSEUS (also ODYSEUS, OLYS[S]EUS, Lat. VLIXES, whereof ULYSSES is a mis-writing), one of the best-known Greek heroes.

(1). In Homer, he is son of Laërtes, king of Ithaca, and Anticleia his queen; he succeeds his father as king, is husband of Penelope (*q.v.*) and father of Telemachus. During the Trojan War (*Iliad*) he is prominent as a brave and skilful fighter, but still more as a giver of shrewd counsel and for his daring and cunning enterprises, alone or with Diomedes. After the war he starts to go home, but driven off his course by unfavourable winds (*Odyssey*), successively visiting numerous unknown regions, (*see* CIRCE, CYCLOPES, LAESTRYGONES, LOTUS-EATERS, SCYLLA), till, losing all his ships and men, he arrives alone on the island of Calypso (*q.v.*). After eight years he is let go, and is wrecked on the coast of the Phaeacians, who receive him hospitably and send him home in one of their ships. All these places are out of the known world, although later writers in antiquity identified them with various regions known to them and have been followed by some moderns. Arrived home, he finds his wife Penelope beset with a number of suitors who are devouring his substance. With the help of Athena, Odysseus and Telemachus, aided by two faithful thralls, kill them all.

(2) After Homer, the character of Odysseus degenerates from a cunning to a wholly unscrupulous and dishonourable man. He tries to shirk service at Troy by pretending to be mad; but Palamedes discovers the trick. In revenge, Odysseus brings about his ruin and death (*see* PALAMEDES). He and Diomedes steal the Palladium (*q.v.*) and in some accounts he tries to murder Diomedes, to get all the credit for himself. After the death of Achilles, Odysseus and Ajax contend for his armour, which is adjudged to the former (*see* AJAX I). He is at length accidentally killed by

Telegonus, his son by Circe or Calypso; this story is worked up from hints in the *Odyssey*. A common legend makes Odysseus son of Sisyphus (*q.v.*), thus bringing the two notorious rogues together.

There is no need whatever to suppose Odysseus other than a real man, renowned for his skill and resource, about whom in the course of centuries numerous fictions have gathered. The plot of the *Odyssey* is a well-known *märchen*, however, and not a saga; *see* M. P. Nilsson, *History of Greek Religion*, p.38. His name is not Greek, and probably belongs to a prehellenic speech.

Bibliography.—J. Schmidt in Roscher's *Lexikon;* P. O. Gruppe, *Griechische Mythologie*, II., 624, 705 ff. (1906); L. Preller and H. Ritter, *Griechische Mythologie*, II. (1865); V. Bérard, *Les Phéniciens et l'Odyssée* (1902–03), and edition of the Odyssey (1924–25) contains the most ingenious attempt to localize his wanderings.

(H. J. R.)

OECOLAMPADIUS, JOHN (1482–1531), German Reformer, whose real name was Hussgen or Heussgen[1], was born at Weinsberg, a small town in Württemberg, but then belonging to the Palatinate. He went to school at Weinsberg and Heilbronn, and then, intending to study law, he went to Bologna, but soon returned to Heidelberg and betook himself to theology. He passed from the study of Greek to that of Hebrew, taking his bachelor's degree in 1503. He became cathedral preacher at Basle in 1515, serving under Christopher von Uttenheim, the evangelical bishop of Basle. From the beginning the sermons of Oecolampadius centred in the Atonement, and his first reformatory zeal showed itself in a protest (*De risu paschali*, 1518) against the introduction of humorous stories into Easter sermons. In 1520 he published his *Greek Grammar*. The same year he was asked to become preacher in the high church in Augsburg. Germany was then ablaze with the questions raised by Luther's theses, and his introduction into this new world, when at first he championed Luther's position especially in his anonymous *Canonici indocti* (1519), seems to have compelled Oecolampadius to severe self-examination, which ended in his entering a monastery for a short time. But in Feb. 1522 he made his way to Ebernburg, near Creuznach, where he acted as chaplain to the little group of reformers who had settled there under the leadership of Franz von Sickingen.

The second period of Oecolampadius's life opens with his return to Basle in Nov. 1522, as vicar of St. Martin's and (in 1523) reader of the Holy Scripture at the university, and after more than a year of earnest preaching and four public disputations in which the popular verdict had been given in favour of Oecolampadius and his friends, the authorities of Basle began to see the necessity of some reformation. They began with the convents, and Oecolampadius was able to refrain in public worship on certain festival days from some practices he believed to be superstitious. Basle was slow to accept the Reformation; the news of the Peasants' War and the inroads of Anabaptists prevented progress; but at last, in 1525, it seemed as if the authorities were resolved to listen to schemes for restoring the purity of worship and teaching. In the midst of these hopes and difficulties Oecolampadius married, in the beginning of 1528, Wilibrandis Rosenblatt, the widow of Ludwig Keller, who proved to be *non rixosa vel garrula vel vaga*, he says, and made him a good wife. After his death she married Capito, and, when Capito died, Bucer. She died in 1564. In Jan. 1528 Oecolampadius and Zwingli took part in the disputation at Berne which led to the adoption of the new faith in that canton, and in the following year to the discontinuance of the Mass at Basle. The Anabaptists claimed Oecolampadius for their views, but in a disputation with them he dissociated himself from most of their positions. He died on Nov. 24, 1531.

Oecolampadius was not a great theologian, like Luther, Zwingli or Calvin, and yet he was a trusted theological leader. With Zwingli he represented the Swiss views at the unfortunate conference at Marburg. His views on the Eucharist upheld the metaphorical against the literal interpretation of the word "body," but he asserted that believers partook of the sacrament more for the sake of others than for their own, though later he emphasized it as a means of grace for the Christian life. To Luther's doctrine of the ubiquity of Christ's body he opposed that of the presence and activity of the Holy Spirit in the church. He did not minutely analyse the doctrine of predestination as Luther, Calvin and Zwingli did, contenting himself with the summary "Our Salvation is of God, our perdition of ourselves."

[1]Changed to Hausschein and then into the Greek equivalent.

See J. J. Herzog, *Leben Joh. Oecolampads u. die Reformation der Kirche zu Basel* (1843); K. R. Hagenbach, *Johann Oecolampad u. Oswald Myconius, die Reformatoren Basels* (1859). For other literature *see* W. Hadorn's art. in Herzog-Hauck's *Realencyklopädie für prot. Rel. u. Kirche.*

OECUMENICAL, a word chiefly used in the sense of belonging to the universal Christian Church. It is thus specifically applied to the general councils of the early church (*see* Council) In the Roman Church a council is regarded as oecumenical when it has been summoned from the whole church under the presidency of the pope or his legates; the decrees confirmed by the pope are binding. The word has also been applied to assemblies of other religious bodies, such as the Oecumenical Methodist Conference, which met for the first time in 1881.

OEDIPUS, the central figure of the Theban saga (Gr. *Oidipous*, probably "Swell-foot"). In Homer we are told that he unwittingly killed his father and married his own mother, Epikaste (the Jocasta of later writers), and that she hanged herself when the matter became known. Oedipus continued, though in great tribulation, to reign in Thebes, apparently until his death. (*Odyssey* xi. 271 *et seq., Iliad*, xxiii, 679). According to the post-Homeric story, Laius, king of Thebes, received an oracle that his son should slay him; therefore, when his wife Jocasta bore a son, he exposed him on Mt. Cithaeron, with a spike driven through his feet. He was saved, however, and was adopted by the childless Polybus, king of Corinth. Reaching manhood, he had occasion to visit Delphi, where he was told that he would slay his father and wed his mother. Departing in great horror, and resolving never to return to Corinth, he met Laius, whom he did not recognize, and killed him in a quarrel. Coming to Thebes, he found the city plagued by the Phix or Sphinx, a winged monster, usually represented with the head of a woman, who asked all passers-by a riddle, killing them if they could not answer. Oedipus solved the riddle, the Sphinx killed herself in disgust, and he was rewarded, according to the promise made by the regent, Creon, son of Menoeceus, with the kingdom and the hand of his sister, the widowed queen. They had two sons, Eteocles and Polyneices, and two daughters, Antigone and Ismene. But later, the whole story came to light; Jocasta hanged herself, Oedipus put out his own eyes, and then lived shut up in a room of the palace (ordinary version), or went into exile, ultimately dying at Colonus and becoming a protecting hero of Attica (Athenian version, *see* Sophocles, *Oedipus Coloneus*). His sons proved undutiful and he cursed them. Therefore they quarrelled over the kingship, finally agreeing to reign alternately. Eteocles' turn came first; Polyneices went into temporary exile, and married Argeia, daughter of Adrastus, king of Argos, whose other daughter, Deiphyle, married Tydeus of Calydon. The latter had gone into exile for homicide; he and Polyneices met and quarrelled, and Adrastus recognized them, by their dress or their shield-devices, as the lion and boar to whom the gods had bidden him betroth his daughters. At the end of a year, Polyneices claimed to rule Thebes in his turn; Eteocles refused, and Adrastus gathered an army to restore his son-in-law. The chieftains, besides the three already named, were Capaneus, Amphiaraus (*q.v.*), Eteoclus, and Parthenopaeus, son of Atalante. Of these, known as the Seven against Thebes, only Adrastus returned. Tydeus would have been made immortal for his valour, but Athena saw him gnaw the head of a slain enemy as he lay dying, and in disgust withheld the intended gift. Amphiaraus was swallowed up in the ground, and in later times was much revered as an oracular hero or god. Polyneices killed Eteocles and was killed by him. Creon now became king; he ordered the bodies of the dead Argives to be left unburied, but Antigone secretly buried her brother, Polyneices. For this, despite the entreaties of his son, Haemon, to whom she was betrothed, Creon walled her up in a tomb (a form of ordeal; the gods might save her if they approved of her conduct). She

hanged herself, Haemon, who had broken into the tomb, killed himself, and so did Creon's wife Eurydice, on hearing the news (so Sophocles; in Euripides, Antigone escaped and lived happily with Haemon, at least for several years; *see* the fragments of his *Antigone* in Nauck). According to an Attic legend, Theseus (*q.v.*) attacked Thebes at the prayer of the mothers of the slain, and forced the Thebans to bury them; Creon was killed by Theseus in the battle. Another story represents him as surviving for many years, to be ultimately killed by the usurper Lycus (so Euripides, *Herc. Fur.,* 33). Oedipus died before, or not long after, the end of the war.

Adrastus bided his time, and when the sons of the Seven (known as the Epigoni, or second generation; hence the application of the word to successors of the Diadochi (*q.v.*), the immediate successors of Alexander the Great) came to manhood, he once more attacked the city. On the advice of Teiresias (*q.v*) the Thebans evacuated by night. Adrastus led his army back, but died on the way, at Megara, from grief at the death of his son Aigialeus, only one of the Epigoni to fall in the campaign.

There is no reason to doubt that this legend has a historical basis, probably in the events of Minoan-Mycenaean times. Gems from Thisbe show incidents strongly resembling the fight between Oedipus and Laius, and the former's encounter with the sphinx. Several incidents, such as the prophecies and the incestuous marriage, are patently folk tales.

Mediaeval Legends.—In the *Golden Legend* of Jacobus de Voragine (13th century) and the *Mystère de la Passion* of Jean Michel (15th century) and Arnoul Gréban (15th century), the story of Oedipus is associated with the name of Judas. The main idea is the same as in the classical account. The Judas legend, however, never really became popular, whereas that of Oedipus was handed down both orally and in written national tales (Albanian, Finnish, Cypriote). The Theban legend, which reached its fullest development in the *Thebaïs* of Statius and in Seneca, reappeared in the *Roman de Thèbes* (the work of an unknown imitator of Benoît de Sainte-More). Oedipus is also the subject of an anonymous mediaeval romance (15th century), *Le Roman d'Oedipus, fils de Layus,* in which the sphinx is depicted as a cunning and ferocious giant. The Oedipus legend was handed down to the period of the Renaissance by the *Roman* and its imitations, which then fell into oblivion. The legend has survived amongst the modern Greeks, without any traces of the influence of Christianity (B. Schmidt, *Griechische Märchen,* 1877). The works of the ancient tragedians (especially Seneca, in preference to the Greek) came into vogue, and were followed by modern imitators down to the 17th century.

See L. Constans, *La Légende d'Oedipe dans l'antiquité, au moyen âge, et dans les temps modernes* (1881); D. Comparetti's *Edipo* and Sir Richard Jebb's introduction to his edition of Sophocles, *Oedipus Tyrannus.* (H. J. R.)

OELS or ÖLS, a town in the former Prussian province of Silesia, Ger., on the Oelsbach, 20 mi. N.E. of Breslau by rail. Pop. (1939) 18,183; (1946) 4,246. Oels was founded about 940, and became a town in 1255. It appeared as the capital of an independent principality at the beginning of the 14th century. The principality, with an area of 700 sq.mi. and about 130,000 inhabitants, passed through various hands and in 1884 it lapsed to the crown of Prussia. The chateau, dating from 1558, was restored in 1891–94, and became after 1918 the residence of Frederick William, the former crown prince of Prussia. The inhabitants are chiefly engaged in making shoes, furniture and machines. Following World War II, Oels was annexed by Poland and became Olesnica in Wroclaw province.

OELWEIN, a city of Fayette county, Iowa, U.S., in the northeastern part of the state; served by the Chicago Great Western and the Rock Island railways. Pop. (1950) 7,858; (1940) 7,801. It is in a farming, dairying, poultry and stock-raising region; has railroad shops and various other manufacturing industries. The city was founded in 1873, by August Oelwein; was incorporated in 1888, and chartered as a city in 1897.

OENOMAÜS in Greek legend, son of Ares and Harpinna, king of Pisa in Elis and father of Hippodameia. It was predicted that he should be slain by his daughter's husband. His father gave him winged horses and Oenomaüs promised daughter to the man who could carry her off in a chariot; himself was to drive after, and spear the suitor if he could ca him. This may be founded on some marriage rite of simula capture. Thirteen aspirants having thus perished, Pelops (*q.* arrived, and won, having winged horses which Poseidon had gi him. He is usually said to have bribed Oenomaüs' chariot Myrtilus to take out his master's linchpins and substitute w dummies; Oenomaüs was thus thrown and killed.

See Diod. Sic. iv, 73; Pausanias vi, 21, and elsewhere; Sophoc *Electra,* 504, with Sir Richard Jebb's note; Hyginus, *Fab.* 84, 253.

OENONE, in Greek legend, daughter of the river god Cebı and wife of Paris, who deserted her to kidnap Helen (*q.v.*). Ju before the capture of the city, Paris, wounded by Philoctet sought the aid of Oenone, who had told him that she alone cou heal him if wounded. She refused to help him, and Paris r turned to Troy and died of his wound. Oenone soon repent and hastened after him, but finding that she was too late to sa him slew herself from grief at the sight of his dead body.

OENOTHERA, the generic name of the evening primro and sundrops, several species of which are favourite garde plants. The genus, comprising numerous species, is confine to America and belongs to the family Onagraceae. The commo evening primrose (*O. biennis*) is often a troublesome weed bot in North America and Europe; the form known as var. *grand flora* or *O. lamarckiana* is a showy plant, sometimes cultivated fo its flowers. Other species grown in gardens are *O. missouriens* and *O. speciosa,* the latter with white flowers, grading to pink The evening primrose acquired importance in connection wit Hugo Devries' theory of mutations. (*See* PRIMROSE; HEREDITY.)

OESEL: *see* SAAREMAA.

OESOPHAGUS, DISEASES OF. (*See* ALIMENTARY CANAL.) The human oesophagus is liable to certain accidents and diseases, from its function and its situation. One of the commonest accidents is the lodgment of foreign bodies. An impacted substance may be removed by the oesophageal forceps, or a coin-catcher or may be pushed down into the stomach. A purgative should never be given, but soft food such as porridge. Should gastric symptoms develop operation may be necessary. Charring and ulceration of the oesophagus may occur from the swallowing of corrosive liquids, strong acids or alkalis, or even of boiling water. Stricture of the oesophagus may be spasmodic, fibrous or malignant. *Spasmodic stricture* usually occurs in young hysterical women; under an anaesthetic a bougie will slip down easily. *Fibrous stricture* is usually situated behind the cricoid cartilage, and results from swallowing corrosive fluids or the healing of a syphilitic ulcer. Occasionally it is congenital. The ordinary treatment is repeated dilatation by bougies. *Malignant strictures* are usually squamous cell carcinoma (*see* TUMOUR) and chiefly occur in males between the ages of 40 and 70 years. An X-ray photograph taken after the patient has swallowed a preparation of bismuth will show the situation of the growth, and G. Killian and Brünig have introduced the oesophagoscope, which makes direct examination possible. Dilatation by bougies must not be attempted, the oesophagus being so softened by disease that perforation might take place. Radium treatment, so far, has not been successful. The method of transpleural approach to the thoracic oesophagus and insertion of radium into the wall of the tube has been introduced, but as yet it is too early to evaluate the results. The most satisfactory treatment is the operation of gastrotomy, a permanent artificial opening being made into the stomach through which the patient can be fed.

OETA (mod. Katavothra), a mountain in Greece, 7,080 ft. high, to the S. of Thessaly (Thessalia), between the valleys of the Spercheius and the Boeotian Cephissus. Its east end, Callidromus, overhangs the sea at the famous pass of Thermopylae (*q.v.*). There was also a high pass W. of Callidromus into the upper Cephissus. In mythology Oeta is the scene of the death of Heracles.

OFFA (757–796), king of Mercia, is the central figure in English history in the second half of the 8th century. A civil war gave him the Mercian kingdom in succession to his cousin

Aethelbald (716–757) who in his later years had been overlord of all the English peoples south of the Humber. The first part of Offa's reign was spent in the re-establishment of the Mercian supremacy. He was strongly resisted in several of the smaller kingdoms, notably Kent, but he succeeded in creating what was in effect a single state covering the whole country between the Humber and the channel. He treated the lesser kings of this country as his subjects, exacting their formal submission, insisting that their grants of land to their own retainers or to churches needed his consent, confirming their charters and requiring them to attend his court. He married one of his daughters to Beorhtric, king of Wessex (789), and another to Aethelred, king of Northumbria (792), thereby extending his direct influence beyond the Humber. His reign marks by far the greatest advance hitherto made toward the political unification of England.

His position was recognized on the continent. His younger contemporary Charlemagne, king of the Franks, regarded him as the outstanding English ruler of his time. Their relations were often uneasy and a personal dispute led to a suspension of cross-channel traffic shortly before 790. Its renewal was followed by a commercial treaty (796) which shows Charlemagne and Offa dealing with each other on equal terms. The closeness of their previous association is illustrated by a rumour current at Rome to the effect that Offa had proposed to Charlemagne the deposition of Pope Adrian I and the election of a Frankish churchman in his place. The pope himself disbelieved the story, but its circulation proves at least the reality of Offa's fame.

Offa, in fact, was on terms with Pope Adrian which enabled him to carry through a remarkable, if temporary, change in the organization of the English church. The archbishop of Canterbury, whose authority covered the whole of southern England, had his seat in the kingdom where Offa's political domination was most strongly resented. To free the churches of his own country from the control of an archbishop belonging to an unfriendly province, Offa induced Pope Adrian to send the pallium which was the symbol of metropolitan authority to Hygebeorht, bishop of Lichfield. It was certainly with Offa's good will, and probably at his request, that in 786 the pope sent two legates to England, who secured the acceptance of a program of reform by the clergy and nobility of both the northern and southern provinces.

It is probable that Offa used this unprecedented mission as a means of acquainting the Roman court with his design of creating an archbishopric of Lichfield. He may well have taken the same opportunity of securing the papal approval for the consecration of Egfrith, his son, as king of the Mercians which took place in 787 and is the first recorded ceremony of the kind in English history.

There still survives a memorial of Offa's effective power in southern England in the remains of the great earthwork known as Offa's dike which he caused to be drawn between his own kingdom and the Welsh tribes beyond his border. It was the object of the dike to draw a boundary line between English and Welsh settlements from the estuary of the Dee in the north to that of the Wye in the south. The line is not now continuous, partly because it has been worn down in the course of 12 centuries, but also because in forest country such as the Herefordshire plain the forest itself was regarded as a sufficient barrier. But on open ground and in the high places of the mountain zone its remains are most impressive. Its line is always drawn so as to command the country to the west and the trackways leading from Welsh into English territory. Throughout its course it shows the activity of a directing mind.

The most permanent achievement of Offa's reign was the establishment of a new form of currency composed of silver pennies bearing the king's name and title and also the name of the moneyer responsible for their quality. They are remarkable for a delicacy of execution and a refinement of portraiture which set the best examples apart from all other coins in the Old English series. Amid infinite varieties of design, the principles governing Offa's coinage were maintained by later kings, and until recent times there has never been any break in the continuity of the English currency since his day. His own attitude toward the currency as an advertisement of the royal dignity is shown by the issue of coins closely resembling his own in type, but bearing the name and portrait of Cynethryth his queen.

No contemporary account of Offa has survived, and the history of his reign is a collection of fragmentary references. The laws which he is known to have issued have long disappeared. There are no adequate materials for a picture of his character. He was a patron of learning and a notable benefactor to many churches, but his rule was arbitrary and he was ruthless to all who opposed him. What can be said is that he left a deeper impression on English history than any other king before Alfred.

Fox, "The Boundary Line of Cymru," *Proceedings of the British Academy,* vol. xxvi (London, 1940). (F. M. S.)

OFFA, the most famous hero of the early Angli. He is said by the Anglo-Saxon poem *Widsith* to have ruled over Angel, and the poem refers briefly to his victorious single combat, a story which is related at length by the Danish historians Saxo and Svend Aagesen Offa (Uffo) is said to have been dumb or silent during his early years, and to have only recovered his speech when his aged father Wermund was threatened by the Saxons, who insolently demanded the cession of his kingdom. Offa undertook to fight against both the Saxon king's son and a chosen champion at once. The combat took place at Rendsburg on an island in the Eider, and Offa succeeded in killing both his opponents. According to *Widsith* Offa's opponents belonged to a tribe or dynasty called Myrgingas, but both accounts state that he won a great kingdom as the result of his victory. A somewhat corrupt version of the same story is preserved in the *Vitae duorum Offarum,* where, however, the scene is transferred to England. It is very probable that the Offa whose marriage with a lady of murderous disposition is mentioned in Beowulf is the same person; and this story also appears in the *Vitae duorum Offarum,* though it is erroneously told of a later Offa, the famous king of Mercia. Offa of Mercia, however, was a descendant in the 12th generation of Offa, king of Angel. It is probable from this and other considerations that the early Offa lived in the latter part of the 4th century.

See H. M. Chadwick, *Origin of the English Nation* (1907), where references to the original authorities will be found.

OFFALY, a county of Ireland in the province of Leinster, bounded north by Meath and Westmeath; west by Roscommon, Galway and Tipperary (the boundary with the first two counties being the Shannon river); south by Tipperary and Leix county; and east by Kildare. The area of the county is 493,636 ac. or about 772 sq.mi. Pop. (1951) 52,544. The greater part of the county is included in the Carboniferous Limestone plain of central Ireland. In the southeast the Slieve Bloom mountains, composed largely of Old Red Sandstone, form the boundary between Offaly county and Leix county and run into the former county from southwest to northeast for a distance of about 20 mi. consisting of precipitous crags through which there are two narrow passes, the Black gap and the Gap of Glandine. In the northeast, basic volcanic rocks rise in Croghan hill to a height of 768 ft. In the centre of the county from east to west a large portion is occupied by the Bog of Allen. Here and there drier deposits of esker gravels rise as green hills above the clay soils and bogs of the plain. The county shares in the advantage of the navigation of the Shannon, which skirts its western side. The Brosna, which issues from Loch Ennell in Westmeath, enters the county near the town of Clara, and joins the Shannon after receiving the Clodagh and the Broughill. A small portion of the northeastern extremity is skirted by the upper Boyne. The Barrow forms the southeastern boundary with Leix. The Little Brosna, which rises in the Slieve Bloom mountains, forms the boundary of Offaly county with Tipperary and flows into the Shannon.

Offaly county, with portions of Tipperary, Leix county and Kildare, at an early period formed one kingdom under the name of Offaly, a title which it retained after the landing of the English. Subsequently it was known as Glenmallery, Western Glenmallery corresponding closely to the present Offaly county and Eastern Glenmallery to Leix county. These two divisions were formed into shires in 1556, being then known as King's county and Queen's county respectively.

In the Slieve Bloom mountains is a pyramid of white stones called the Temple of the Sun or the White Obelisk. There are many Danish raths, and a chain of moats commanding the passes of the bogs extended throughout the county. On the borders of Tipperary is an ancient causeway leading presumably to a crannog or lake dwelling. The most important ecclesiastical ruins are those of the seven churches of Clonmacnoise (*q.v.*) on the Shannon in the northwest of the county, where an abbey was founded by St. Kieran in 648 and where the remains include those of churches, two round towers, crosses, inscribed stones and a castle. Other famous religious houses were Durrow abbey, founded by St. Columba in 550; Monasteroris founded in the 14th century by John Bermingham, earl of Louth; and Seirkyran abbey, founded in the beginning of the 5th century. The principal old castles are Rathmore, probably the most ancient in the county; Banagher, commanding an important pass on the Shannon; Leap castle, in the Slieve Bloom mountains; and Birr or Parsonstown.

The whole of the county would appear to have been covered formerly by a vast forest, and the district bordering on Tipperary is still richly wooded. The soil is generally either a deep bog or a shallow gravelly loam. On the borders of the Slieve Bloom mountains there are some very rich pastures, and there are also extensive grazing districts on the borders of Westmeath, chiefly occupied by sheep. Along the banks of the Shannon there is good meadowland. With the exception of the tract occupied by the Bog of Allen, the county is nearly all under tillage, the most productive portion being that to the northwest of the Hill of Croghan.

Oats, barley and rye, potatoes and turnips, are all considerably grown. Cattle, sheep, pigs and poultry are widely bred; dairies are numerous in the north of the county, and the sheep are pastured chiefly in the hilly districts.

The county is traversed from southeast to northwest by the Portarlington, Tullamore, Clara and Athlone line of the Great Southern railway, with a branch from Clara to Banagher; other branches run from Roscrea (County Tipperary) to Parsonstown (Birr), from Enfield (County Kildare) to Edenderry and from Streamstown (County Westmeath) to Clara. The Grand canal runs through the county from

east to west, entering the Shannon at Shannon harbour.

The administrative counties of Leix and Offaly together return five members to *dail eireann.*

OFFENBACH, JACQUES (1819–1880), French composer of *opéra bouffe,* was born at Cologne, of German-Jewish parents, on June 20, 1819. In 1833 he was sent to Paris to study the violoncello at the Conservatoire. As a member of the orchestra of the Opéra-Comique he turned his opportunities to good account and eventually was made conductor at the Théâtre Français. His first complete work, *Pepito* (1853), was followed by a crowd of light dramatic pieces which effected a complete revolution in the popular taste of the period. Offenbach obtained a lease of the Théâtre Comte in the Passage Choiseul, reopened it in 1855 under the title of Les Bouffes Parisiens and produced a succession of brilliant, humorous trifles. Among many other librettists Ludovic Halévy was associated with him from the first, but still more after 1860, when Halévy obtained Henri Meilhac's collaboration. The series culminated in 1867 with *La Grande Duchesse de Gérolstein,* perhaps the most popular *opéra bouffe* ever written, not excepting even his *Orphée aux enfers,* produced in 1858 and refashioned in 1874, and *La Belle Hélène* of 1864. In 25 years Offenbach produced more than 100 complete dramatic works, including two ballets. Offenbach died at Paris on Oct. 4, 1880. *Mamzelle Moucheron* was produced posthumously in 1881. *Les Contes d'Hoffmann,* his only opera as distinct from operettas and other light pieces, became the most popular of all his works. He left it unfinished, and it was completed and orchestrated by Ernest Guiraud.

David and E Mosbacher (London, 1937; published as *Orpheus in Paris,* New York, 1938); L. Schneider, *Offenbach* (Paris, 1923); S. Sitwell, *La Vie Parisienne: a Tribute to Offenbach* (London, 1937; New York, 1938).

OFFENBACH, a town of Germany, in the *Land* of Hesse, on the left bank of the Main, 5 mi. E.S.E. of Frankfurt-on-Main, with which it is connected by the railway to Bebra and by a local electric line. Pop. (1950) 89,030. The earliest mention of Offenbach is in a document of 970. In 1486 it came into the possession of the counts of Isenburg, and in 1816, when their lands were mediatized, it was assigned to Hesse. French Protestant refugees settled there at the end of the 17th and the beginning of the 18th century and brought prosperity which increased with the accession of Hesse to the German Zollverein in 1828. The most interesting building in the town is the Renaissance château of the counts of Isenburg. Offenbach is the principal industrial town of the *Land,* and manufactures include chemicals, boilers, machines, wire goods and celluloid. Its characteristic industry, however, is the manufacture of fancy goods in leather.

OFFENBURG, a town of Germany, in the territory of Baden, 27 mi. by rail S.W. of Baden, on the Kinzig river. Pop. (1939) 20,521. Offenburg is first mentioned about 1100. In 1223 it became a town; in 1248 it passed to the bishop of Strassburg; and in 1289 it became an imperial free city. Soon this position was lost, but it was regained about the middle of the 16th century, and Offenburg remained a free city until 1802, when it became part of Baden. The chief industries are dyeing and the making of cotton, linen, silk, cement, machinery, cigars and glass.

OFFICE, a duty or service, particularly the special duty cast upon a person by his position; also a ceremonial duty, as in the rites paid to the dead, the "last offices." The term is thus especially used of a religious service, the "daily office" of the English Church or the "divine office" of the Roman Church (*see* BREVIARY). It is also used in this sense of a service for a particular occasion, as the Office for the Visitation of the Sick, etc. For the "Holy Office" *see* INQUISITION.

OFFICE MACHINES AND APPLIANCES. For a variety of reasons the work load of the modern business office increased in striking fashion during the 20th century. Much of this work is repetitive and routine, and development and use of office machinery has been the natural result.

The decision to shift from manual to machine operation is, of course, determined by a comparison of costs incurred with costs saved. Specifically, the following items are important in assessing the desirability of mechanizing office tasks:

1. The desirability of saving labour. This is basically a matter of determining estimated savings in office direct labour charges over the life of the equipment, and comparing these savings with estimated machine costs.

2. The desirability of saving time. Time saved in office routine may greatly improve operations elsewhere in the enterprise. On the other hand no advantage may derive from time saving. The latter is usually true where the volume of work in the office is so small that the machine under consideration is likely to stand idle most of the time.

3. The importance of accuracy. Although accuracy is always desirable the consequences of error, in terms of cost, vary considerably in different situations.

4. The effects upon personnel. Mechanization involves important changes in job requirements. Training and morale problems must also be anticipated. Difficulties in this area may create an unfavourable cost situation which will nullify the savings discussed under 1.

The major office machines in current use are described below. They are classified according to the relationships of the operations that they most commonly perform.

Writing and Reproducing Machines.—The majority of office machines fall into this category, and the bulk of the office work load is handled by them. Thousands of accessories are available to permit performance of various detail operations.

The typewriter, most common of office machines, produces text material on a page in type similar to printer's type. On the manual typewriter this is accomplished mechanically when the operator strikes keys arranged on a keyboard. Type bars, containing raised characters and actuated by the keys, strike the page. Printing is accomplished by the automatic interposition of an inked ribbon between the type bar and the page. The page is held in position against a movable cylindrical rubber roll or platen. The platen, in turn, is mounted in a carriage which travels transversely. This arrangement permits vertical and horizontal spacing.

Electric typewriters use electrical power to multiply the energy of the operator's touch. Noiseless typewriters utilize a special type bar to reduce the noise of the impact of the type bar upon the page. Correspondence typewriters employ a specific type face, letterspacing and line spacing. Special-purpose typewriters utilize a variety of special attachments to achieve variation in type face and spacing. The Vari-Typer, in appearance and operation a typewriter, is actually an office type-composing machine permitting production of copy in any of hundreds of type faces. Completely flexible letterspacing produces copy on this machine closely resembling typeset material. Automatic typewriters are power-driven machines which operate from a "player piano" type roll which has been cut on a standard typewriter. These machines are used for mass production of material with a hand-typed appearance. Special inserts can be made manually at predetermined points in the copy.

The typewriter when used in conjunction with a computing machine functions as a bookkeeping machine. This type is best considered as a variety of accounting machine, discussed below.

Dictating and transcribing machines provide for storage, and later reproduction, of spoken messages. Dictating machines, by a combination of electronic and mechanical means, record the voice on a variety of mediums, including wax cylinders, plastic disks, wire and coated tape. These materials can be removed from the machine after dictation and transported (even by mail) to the point of transcription. The transcribing machine, in a manner similar to the dictating machine, reproduces the voice. By use of these machines stenographic transcription tasks can be fitted into the working time of both the executive and the stenographer in much better fashion than when dictation is taken directly by the stenographer.

A large variety of duplicating machines has been developed. Regardless of variation in process, all of these machines utilize a master copy prepared manually, from which duplicate copies are made by the machine. Before describing these specific processes, note should be made of the fact that the use of carbon paper inserts makes the typewriter into a duplicating machine. Used extensively when a small number of copies is desired, this process has a practical limit of about 12 copies on the manual and about 18 copies on the electric typewriter.

The stencil method of duplicating employs a coated fibre sheet

(the stencil). Use of a typewriter (without ribbon) or a hand stylus places the copy on the stencil by simply pushing aside the coating and exposing the fibre base where contact is made with the stencil. The exposed portion will transmit ink. The stencil is fastened to the outer surface of a hollow rotating cylinder. The padded interior surface of the cylinder is saturated with ink. The ink flows to the stencil through the pad as the cylinder rotates. Simultaneously sheets of paper are passed under the cylinder and applied to the stencil under light pressure. Up to 5,000 copies can be made in this fashion from a single stencil. Stencils can be stored for reuse for considerable periods of time.

The hectographic method of duplicating uses a paper master sheet. In the liquid process the master is prepared with a special carbon paper behind it. This results in a reversed carbon image. The master sheet is then fastened to a rotating drum. Copy sheets, slightly moistened by a special liquid, are applied in the same fashion as for the stencil method. A minute amount of the carbon is thus transferred to the copy sheet.

The gelatin process requires the use of a special master paper upon which the copy is typed or written. This sheet is then pressed, face down, against a prepared moist gelatin surface and the image is transferred to the gelatin in reverse form. Copy sheets pressed against this gelatin receive an image impression. The impression process can be accomplished on a machine similar to that used in the stencil method. The practical limit on hectographic copies is about 300. It is possible to preserve the master copy in the liquid process only.

Offset processes of duplicating require chemical fixing of copy on a metal sheet or, in more recent developments, preparation of a paperlike master copy. This master impression is inked and brought against an intermediate composition agent (usually rubber) to which the image is transferred. The image is immediately transferred to a copy sheet. This operation is performed by a power-driven machine. Many thousands of copies can be produced and masters can be stored for indefinite periods.

Raised-image duplicating processes use a variety of techniques for producing a master form on which the text stands in relief. Typesetting machines closely resemble those used in the printer's office. Another machine, commonly used for production of form letters or for addressing envelopes, uses a soft metal strip or plate upon which the text is embossed. When used for addressing, the machine feeds the plates into place in rapid succession. This machine has also been adapted to pay-roll printing work.

A group of various photographic processes have been devised for producing copies of drawings or written material. The contact processes operate without use of a camera or lens. The most commonly used processes in this category are blueprint and dye line. In the first process the master (typed, drawn or printed upon a translucent paper or cloth sheet) is placed upon sensitized paper and exposed to light. The paper is then developed by wetting in a chemical solution and washing in clear water. Dye line operates in similar fashion, but avoids washing in clear water. A dry-line process uses ammonia fumes rather than liquid to develop the image and thus obviates problems of paper shrinkage. In both blueprint and dye line, machines have been developed which perform all operations automatically.

In contrast with the contact processes are the camera processes, wherein cameras are used to "take pictures" of the material to be reproduced. In most processes a negative results from which positive copies in various sizes may be produced. A modern development is the microfilm process, which uses a special camera to produce a direct positive copy, in greatly reduced size, upon 16-mm. or 35-mm. movie film. This process is invaluable in saving space when storing documents of all sorts. Documents are read by projecting the microfilm image upon a screen.

A host of specialized reproducing machines exist. The most widely used are cheque-writing machines which print names on cheques so that they cannot be altered; and cheque-signing machines. Numbering, dating, receipting machines are small devices manually operated, the names of which are largely self-descriptive. The machines, which use rubber or metal type form, are preset to produce correct impressions.

Computing and Accounting Machines.—These machines, widely varied in form, handle the arithmetical tasks common to most offices. They are frequently combined with certain other writing and reproducing machines mentioned and, in such form, produce a high volume of work with a minimum of error.

Adding and subtracting machines perform the arithmetical operations indicated by the name. Some varieties list figures on a paper tape; some do not. Keys on the machine are depressed in proper order to set the mechanism in operation. Key-driven machines operate the mechanism directly upon pressing the keys. Crank-driven machines need the additional operation of pulling a lever. In many cases electric motors, actuated by depressing a bar, perform the bulk of the work of operation. Full keyboard machines provide a column of ten keys for each digit position. Ten-key machines have only ten keys with digit position being shifted to the left successively with each depression of a key. This latter type keyboard is especially useful when large numbers are involved.

Registering machines are listing-type adding machines designed for special tasks. Cash registers simultaneously record cash transactions on a tape, produce printed slips and operate cash drawers. These machines keep running totals of the transactions, classified into a number of categories. Calculating machines are designed to perform multiplication and division operations. They are also used for addition and subtraction. Commonly electrically powered, these machines may be of a printing (listing) or non-printing type. Keyboards, again, may be either full or ten-key type.

Note should be taken here of the development of electronic-mechanical calculators capable of performing extremely complex computations. These are beyond reach of the typical office because of cost and the high skill required of operators. The services of these machines are available in some areas on a fee basis.

Accounting machines (or bookkeeping machines) are complex machines combining features of the computing machines already described with some provision for writing. These machines take over much of the labour of bookkeeping. Billing machines, for example, are designed to write (with the built-in typewriter) name, address and description, to multiply and extend, to figure discounts and to add net total.

Accounting machines typically post to several accounts simultaneously and frequently accumulate in the manner of cash registers to permit summarizing and distributing accounts. The window-posting accounting machine is in common use in banks, hotels and retail stores. Customer statements or books are inserted into the machine. The transaction is printed on these forms as well as on an audit sheet. After automatically calculating new balances the machine prints these balances on the forms described.

Classifying, and Selecting Machines.—These machines are characterized by use of cards upon which coded data is recorded; their function is to facilitate sorting and tabulation of numerous diverse data. A common use in the office is preparation and presentation of accounting data.

The simplest card systems function by notching the perforated perimeter of the card according to some code. These systems are limited to performance of sorting tasks. They are operated by a simple machine or device (frequently merely a metal rod) which is inserted in a specific perimeter location of a stack of cards. It will thus penetrate both notched and unnotched holes. When the rod is lifted those cards with notched holes will fall out.

The punched-card system uses a card which can be punched throughout its area. Data is punched into these cards according to a specific code. When the cards are passed through any of various machines the punched holes cause transmission, by mechanical or electrical means, of impulses to other functioning parts of the machines. Basic machines are the punching machine which punches data into the cards, the sorting machine, which sorts out cards according to various classifications, and the tabulating machine which prepares printed reports from the sorted cards.

The punched-card system is extremely flexible and permits sorting and tabulation of an immense number of items. In addition to accounting uses, the system is very useful in market research work,

production planning, materials ordering, etc.

Coin-Handling Machines.—In some offices large quantities of coins must be handled. To facilitate this job a variety of machines have been developed to sort, count, wrap or dispense coins.

Sorting is accomplished by the simple process of "sifting" the various size coins. Trip counters count the coins. Wrapping machines wrap a standard number of coins in a standard paper wrapper. The coin-dispensing machine releases a specific sum in coin, upon depression of the appropriate key on a keyboard similar to that of an adding machine. The coins are stacked in the machine in trays.

Mail-Handling Machines.—These are designed to expedite handling of large quantities of incoming and outgoing mail. The bulk of the work occurs in handling outgoing mail and most machines, consequently, are designed to aid in the mailing task.

Folding machines, inserting machines and envelope sealers, with self-explanatory titles, perform the tasks of placing letters in envelopes. Stamp-affixing machines mechanically separate stamps from a roll, moisten them and apply them to envelopes. Postage meters print stamp charges directly on a dry or moistened adhesive strip. The machines are set by postal employees to yield a number of impressions according to the amount of deposit paid.

Intercommunicating Systems.—The modern office is frequently of such size that efficient communication becomes a key item in maintaining the flow of work. Equipment described in this section is utilized to speed and improve communication between specific posts (desks, counters, etc.) or persons in the office; it includes, of course, the public telephone system.

Paging systems are used in conjunction with the telephone system for locating persons not accessible at their usual posts. One such system involves dialling of a special number (a portion of which is specific to the individual being sought), whereupon a special audible signal is sounded. The person being paged may, upon hearing the signal, pick up any telephone, dial another special number and be connected with his caller. Other paging systems use the amplified human voice to request an individual to call a given number.

Two-way voice systems operate on the telephone principle. In a commonly used version, the individual may call any one or any combination of a limited number of stations by depressing appropriate keys on the receiver-transmitter box. When he speaks into the box his voice, amplified electrically, is broadcast from similar boxes at the various stations. Others may then reply in similar fashion from their stations.

Telewriting and teletype systems provide written or typed communications between two or more points. Messages are received and recorded even though no person is in attendance at the receiving machine. These systems are especially valuable for rapid intercommunication among a number of widely separated offices. Teletype systems, for example, frequently span the entire country.

Conveying systems are available for very rapid transmission of small materials. Pneumatic tubes are frequently used in retail department stores for movement of sales tickets, cash, etc.

Paper Processing Machines.—To aid in changing the form or size of large quantities of paper, paper cutters, paper punches, binding equipment and folding equipment are available in a wide range of sizes. The names are nearly self-explanatory.

Document destroying equipment disposes of outdated paper documents by shredding or chopping. Collating equipment provides mechanical aid in assembling pages of printed matter in a specific order. As is frequently the case with office machines, the equipment designed for high-volume output is motorized, while smaller models are manually operated.

Time-Recording Machines.—Machines in this category combine a clock mechanism with a recording device. The objective is to provide a quick, correct recording of the time of occurrence of certain routine events.

Time stamping machines are manually actuated machines which stamp the correct time (at stamping) upon letters, documents, etc., which are inserted in the machine. Time-recording clocks record the times of arrival and departure of employees from the office (or other workplace.) This is accomplished by the employee's inserting a special card into the machine at the time he arrives, and again upon departure. Job recording clocks function in identical fashion to record time of beginning and finishing particular tasks.

(W. H. Le.; H. E. Wp.)

OFFICE MANAGEMENT. The office is that part of an enterprise which is devoted to the direction and co-ordination of the various activities of the enterprise. It is characterized by the gathering, classification and preservation of data of all sorts; the making, using and preservation of all kinds of records; the analysis and utilization of these data in planning, executing and determining the results of operation; the preparation, issuing and preservation of instructions and orders and the composition, copying and filing of written messages.

Though clerks and clerical work have existed for centuries and large groups of clerks for decades, it is only in recent years that the management of clerks or office management, has become a problem of importance. This is wholly due to the rapidity of industrial change, which is best shown in the United States. In 1880, when there were but 172,575 clerks in that country, mostly bookkeepers and accountants, the problem might be considered as practically non-existent; but in 1920, when the number of clerical workers of all kinds had grown to 2,951,008, it assumed proportions that could not be ignored. In 1920, one in ten of all persons engaged in "gainful occupations" was a clerical worker. The change was necessitated by the exigencies of an ever-growing large-scale industry. While business organizations were small, and direct contact existed between producer and consumer, beyond simple bookkeeping few records were required, there was little written communication between sections of an organization, and consequently few clerks were needed. All this has changed, and to-day the office has attained a position of major importance in business.

Many offices employ more than 100 clerks each and a considerable number employ several thousands. Evidently the employment of such numbers of workers requires management of a high order, yet it is only recently and among the most progressive companies that the subject has received the attention it deserves. Ingenious systems of record keeping and filing have been invented, scores of clever appliances and marvellous office machines are available (*see* OFFICE MACHINES AND APPLIANCES), but the problem of securing the greatest result for the least expenditure of effort has not been given the attention in the office that it has in other lines of endeavour. This is due to the newness of the problem, but there are signs that this condition is sure to change as time passes.

Frederick Winslow Taylor (*q.v.*), the "father of scientific management," was himself probably the first person to apply—at least in a limited measure—scientific principles to office work. In Copley's biography of Taylor is shown a "Time Note," dated about 1885, giving "piece-work" rates on 17 clerical operations, the implication being that Taylor had at least studied these operations, found the best method of performing them and controlled them to the extent that he offered an incentive wage for their accomplishment.

THE HUMAN ELEMENT

The major divisions of office work are given herewith, but not necessarily in the order of their importance.

Organization.—The most essential factor here is clearly defined lines of authority, and its lack is the greatest defect to be found in many companies. In the struggle for advancement it seems difficult to prevent officers from claiming more authority than is granted them, and where confusion of this kind exists, loss of morale invariably results. Functionalization—one of the leading principles of scientific management—is as efficacious in the office as elsewhere. The office manager himself holds a functional position—that of managing clerks, wherever placed. Where this principle is fully carried out, work, instead of being departmentalized, will be functionalized, and therefore performed much more effectively. Thus, a stenographer employed exclusively in taking notes and transcribing letters, will do much more effective work than one who also keeps and files records, answers telephone calls

and performs other miscellaneous work. Functionalization, however, is to its fullest extent only feasible in large offices. It is uneconomical to have too many departments under the charge of one officer. A chart of the organization, and an organization diagram, both giving not only the position of each individual in the office but his duties and relation to others, are necessities. Also there should be standard methods for performing each task, and written standard practice instructions so that the carefully devised methods may be perpetuated. Otherwise great loss of output will result.

Personnel Methods.—Progressive records of each employee's performance are necessary as they serve as a basis for future advancement. Special tests for ascertaining the ability of new employees will prevent to a large extent the great wastage of continuous hiring and discharging. Many psychological tests, special ability and trade tests have been prepared, extensively used and found advantageous. (*See* PSYCHOLOGICAL TESTS.) While there are many clerical positions which demand the very highest intelligence, all clerical work does not, and much of the simpler clerical work is found irksome when allotted to those capable of a higher grade of activity. Training is extremely important, though often sadly neglected. In some offices the various lines of promotion are laid down and made known to all employees, so they can prepare themselves for advancement. Some offices also have officers who devote their activities wholly to employment, and all persons who are to be discharged are referred for final adjudication to this officer—the employment manager. The advantage here is that competent employees are not lost to the organization solely because of the personal pique of some hasty or temperamental officer. The employment manager also ascertains by tactful questioning the reasons why employees leave, and by a careful, classified record of such reasons is enabled to check bad practices, and to determine any other causes for dissatisfaction.

Turnover.—The "rate of turnover," that is, the ratio of employees leaving to those on the pay roll, is a most important factor in good office management. An average cost of over $100 is represented in the training of a new employee who replaces one who has left, so that it is evidently desirable to retain employees for long periods. Turnover is dependent upon many factors. If employees are not properly selected, many replacements will be needed; if salaries are not right, physical conditions bad, or the relations of officers not as they should be, there will be many voluntary separations. A minimum turnover is considered to be about 10% annually. Length of service depends upon much the same conditions as rate of turnover.

Routines and Methods.—A routine is a collection of separate operations through which a piece of work successively passes. Division of labour has been highly developed in office work, and few operations are complete in themselves. Routines as a rule are seldom consciously developed but come into existence gradually through the use of machinery combined with hand-work. As a result, operations wholly or partially useless and of little or no value to the "finished product"—the result desired—are frequently found. Methods also have generally speaking a similar evolution, and yield great results from scientific research. Unless both routines and methods are carefully studied, there is apt to be much waste.

Control of Output.—To secure maximum results for minimum effort, a continuous and uninterrupted flow of work is necessary, and this is one of the most difficult achievements in office work. In the manufacturing of any material commodity the work can be precisely scheduled, step by step, and the maintenance of a steady flow is largely a mechanical problem, as every piece of similar character goes through precisely the same steps. But in the office there is the added difficulty that office work of similar character does not always take the same course; and even in some work of exactly the same nature, the flow is governed by conditions beyond the control of the office manager. Because of this fact it was, until very recently, considered impossible to plan and schedule office work. Peaks, that is, periods demanding intensified and additional work, were handled either by overtime work, or by the permanent maintenance of a sufficient force of clerks to handle them, both plans being evidently wasteful. Analysis of this matter, however, showed that in many cases they could be adequately met by pre-planning. The office force should be well balanced, and sufficiently large to handle average conditions; but a sufficient number of clerks should be trained in several operations. Then by utilizing the idea of the "flying squadron"—a selected group of clerks that can be used almost anywhere in an emergency—most of the minor peaks can be handled without difficulty. Major peaks can be dealt with by a re-adjustment of working force and the employment of extra clerks for positions which require only a minimum of training.

Clerical Output.—On this subject all the major factors of office management converge, and all have a bearing upon it. Under conditions where all factors have been scientifically studied, clerical output is invariably much greater than in organizations in which they are largely ignored. Thus in the office of the latter character the average output of a stenographer will rarely exceed 100 sq.in. per hour, while in a scientifically managed office this particular output will be increased to an average of 200 sq.in. per hour. The maintenance of the latter rate does not depend alone upon the skill and application of the stenographer—for 200 sq.in. per hour is but 30 words a minute, while the world's typewriting record is over 800 sq.in. per hour—but largely upon other factors outside the control of the operator and decidedly within that of the office manager. As with typewriting, so it is with all other clerical operations; the output usually depends much more upon the efforts of the management than upon those of the individual clerk. The effort should not be to obtain the highest possible output from any individual, but that which should be expected from a first-class worker.

The Incentive Wage.—Still another factor which aids in obtaining a high clerical output is an incentive wage of some kind, wherever it is possible to measure the work. The various methods of incentive wage used in other lines of business endeavour have all been tried in the office, some with considerable success, others with disastrous results. In the cases of failure the main causes generally are that (1) work was not properly standardized; (2) not properly measured; (3) steady flow not obtained; (4) work not properly controlled; and (5) no adequate check upon its quality. Piece-work in the office is not so generally applicable, because the worker must have a guaranteed minimum wage, and it is not always possible to supply him with sufficient work to make that wage on a piece-work basis.

THE MECHANICAL SIDE

The preceding factors deal almost wholly with the management of the human element, and now other factors must be considered—those physical factors without which efficient management is not possible.

Arrangement.—The physical arrangement of an office affects all other factors of management. As most offices are in large cities, rentals are high and therefore space must be conserved. For this reason the cubicles of the old-fashioned office are giving way to the open office. Departments having relations with each other should be contiguously situated, and the seating of the workers in each department be regulated also on this principle. Work should flow in straight lines. Adequate light, both daylight and artificial, should be provided, the standard of the latter being placed by experts at not less than 10 foot-candles. (*See* ILLUMINATING ENGINEERING.) The completely indirect system, in which the light is thrown from its source to the ceiling, and thence reflected down, is considered the best. Ventilation is an important matter also. Experiments show that the best ventilating system is that which brings in fresh air from the outside without altering it in any way, this being superior to the elaborate washed and heated air systems. (*See* HEATING AND VENTILATION.) Excessive noise is also detrimental to good work, and noisy machines, if numerous, should be segregated.

Equipment.—Under this head are included desks, tables, chairs, filing cabinets and similar furnishings. The old-fashioned roll-top desk has disappeared, and as the present tend-

ency is to the extended use of small loose-leaf books and cards, the high-standing book-keeper's desk is seldom seen. At present the usual office desk is too large and contains too many drawers, and as clerks have little need for more than one or two drawers, a table is generally preferable. The size of a desk depends naturally upon the character of the work, but a desk larger than 54×30 in. is rarely needed, though no desk should be smaller than 40×30 inches. Chairs to be comfortable require designing to fit the human anatomy in an upright seated position. A few good anatomical chair types are available, but most of the others are uncomfortable.

Office Machinery.—Here the greatest development has taken place, office appliances being now available for almost every occasion. (*See* OFFICE APPLIANCES.) There was a tendency to use machines to the exclusion of competent brainwork, but office managers are beginning to see that this is a mistake.

Correspondence.—This is naturally an extremely important part of office management, not only between the company and outside correspondence, but within the organization itself. The present tendency is toward brevity and clarity, and the florid style and redundant expressions of the so-called "business English" are in process of elimination.

Filing.—The vertical system of filing has almost entirely superseded the old-fashioned flat file, and elaborate systems have been greatly simplified. Its greatest present misuse is the filing of valueless and superfluous material. The filing problem requires not only adequacy in equipment and system, but also accuracy, which necessitates adequately trained operators, for misfiled papers may easily cause great loss.

Stock-keeping.—In a large office the maintenance and issue of an adequate stock of all forms in use becomes a problem in scientific stock-keeping. Order and neatness are necessary, and an adequate location system, so that material can be found with a minimum loss of time. Stores should be classified according to some well-devised system, and there should be a perpetual inventory and a systematic method of issuing stores to, or on the order of, authorized persons.

Intercommunications.—This factor is a most important one in large offices. The telephone is of course the most common method, but there is usually a large transfer of papers from one part of the organization to another, and this must be taken care of by well-organized messenger systems with regularly scheduled trips. In many offices automatic belt systems or other forms of conveyors are used. Mechanical devices of other kinds are automatic signalling systems, automatic telephones and so forth.

Forms.—Most office work is performed by writing upon some kind of blank form, whether they be detached or loose-leaf forms. The quality of paper selected for any form should be governed by the use to which it is put. If it is to be written upon with pencil it is wasteful to use a high-grade paper designed for writing with ink. When forms have a temporary value only, the paper should be of a cheaper quality than that of forms to be kept for a number of years. Selecting standard qualities of paper for these various purposes requires considerable study. A large variety of colours should not be used, as many of them—particularly the reds and blues with their varying shades—are difficult to read under artificial light. Not more than nine standard sizes of forms are usually needed.

Salary Standards.—In most offices salaries vary widely and often unreasonably, clerks doing similar work frequently receiving widely different salaries. Some of the best-managed organizations have made a careful gradation of salaries, with a maximum and minimum for each class of worker. The minimum is that salary which a clerk is entitled to as soon as he is assigned his position, and the maximum the highest salary which the company can afford to pay for that type of work. Such gradation eliminates gross inequalities, gives more equitable payment for results and minimizes dissatisfaction among the office force.

SUMMARY

Office management is highly complicated, and requires a specialist—a manager of high order who at the same time thoroughly understands clerical work. The scientific approach to the factors of office management may be briefly defined. First it is necessary to define thoroughly the purpose of any work about to be undertaken, for if this is neglected the path of the subsequent investigation is likely to follow incorrect lines. Then the problem should be carefully analysed by dividing it into its factors. These preliminary steps, though simple in a statement, are by no means so simple in fact. The next step involves a careful search for all the facts in the situation which govern each and every factor in the analysis. It is a very common oversight to gather an abundance of facts on one part of a problem, and ignore or minimize other parts. To infer, without investigating, is a most prolific source of error, the method of actual test being by far the best. These three steps are precisely those of experimental science, and may be called the scientific method of thinking out a problem. By its use, the office manager can correctly approach each problem and devise the right method, otherwise known in management as "the one best way." With the best method secured, it is then necessary to select the person best fitted to perform it, for all cannot be equally proficient in the same things. The person best fitted for any particular task will invariably produce better results than the so-called "average" person. When found, it then becomes necessary to teach the person who has been thus selected.

These six steps constitute the basic procedure in any form of scientific management and lead up to the seventh, which is planning. Without careful planning, all the scientifically designed work which has gone before will be wasted. Finally, to secure the best results it is vitally important to win the co-operation of the workers. An office force labouring without interest or enthusiasm will accomplish some results, but certainly not of the type desired by a competent office manager. The management which does not and cannot secure co-operation is necessarily defective. These eight steps cover the basic principles of scientific management in all activities.

There is also a considerable tendency toward the simplification of office methods and the entire elimination of much that has been done in the past, on the ground that it is either superfluous or not worth the effort expended. These tendencies are continuously accelerated by economic conditions. Scientific management will be the principal means of reducing the numerical growth of office workers. (W. H. LE.)

OFFICERS, a term designating persons holding army, navy, and air force commissions, and differentiating them from the enlisted military and naval manpower of a nation. The term "officers" usually refers to commissioned men and women on active, or full-time, duty and indicates that there is a contractual arrangement between them and the state. These persons devote themselves to their country's defense as a principal and regular means of gaining a livelihood. Reserve officers and commissioned militiamen are also included as officers when on active duty, though social custom maintains the use of the term for them when on inactive duty. In a way, this is recognition of the all-inclusive nature of universal service in the age of total warfare. The large group of reserve and militia officers in all nations qualifies in some measure under the term officer, since they give part-time service to the state under less binding contractual agreements. However, their military profession is secondary to business and professional pursuits. Therefore, the term officer in the following context will usually refer to the commissioned members of the regular, active armed forces.

What is the function of officers? They are, in effect, the third side of the triangle of preparedness. Armed forces exist for the primary purpose of defending their nation First the forces must be recruited, organized and equipped. Secondly, they must be trained; thirdly, leaders must be developed.

The art of military leadership for war is based on uncertainty.

The officer may prepare for the day of battle for many years, but the exercise of his leadership in war occupies a relatively brief period. Admittedly, the officer cannot gain experience in the profession of arms during peacetime, which will assure good leadership in war. What he has learned by study and experience may be outdated before he is called upon for wartime leadership. Therefore, the great emphasis among the officer corps of all armed forces is upon training. Theory is the basis of training. Even though theory, when compared to practical experience, is often considered less important, it remains the sole method of disciplining the minds of military leaders. Knowledge is important; the ability to take positive action still more so. The officer must be thoroughly trained, must acquire a knowledge of the principles of war, and retain a certain flexibility in their application to a particular situation.

Leadership has always been a vital requirement of all officers. Their position is one of responsibility, one which carries with it authority over the action of others. The term is used widely in fields other than the military, but there is less conflict in civil life over the connotation of the term. This may well be because there is no such long tradition of leadership by the nobility as has been true of military leaders. Military leadership in modern armies is based upon ability, not social position.

Yet, unfortunately, the social status of officers in history, when they were members of the nobility, was carried over by some misguided individuals into the 20th century. False ideas of the prerogatives of the officer position at times created friction between the enlisted and commissioned ranks.

Accordingly, the primary endeavour in armed forces worldwide was to bring the two groups closer together. All major nations drew their military officers from a cross section of their people, made it possible for the enlisted man to achieve officer status by rising through the ranks, and stressed a form of cooperative discipline born of mutual confidence and assisted by moral incentives for all members of the military and naval professions.

HISTORICAL DEVELOPMENT

Ancient and Mediaeval.—The armies of ancient times were normally commanded by members of the nobility, particularly in Egypt, where members of the military profession were ranked as the second of seven castes. Later in Assyria, the nobility were not only the military leaders but also the top social group in the nation. In neither of these cases could the nobility who commanded this group be considered officers in the sense that their livelihood was primarily military. Moreover, they were not bound to the state by a contract.

The citizen-soldiers of both Greece and Rome were officered by those from among their number who exhibited qualities of leadership. However, in both states, the citizen-soldiers eventually resigned their position as amateurs to professional, long-service, regular soldiers. As a result, citizens in Greece and Rome who had a liking for the military remained in service as officers. Usually they commanded lower-class citizens of their nations, mercenaries and barbarians. Marius opened the officer ranks to Roman citizens regardless of their position. Naturally the sons of prominent men had an easier road to an officer's commission though they had to prove themselves in the frontier battles. In a sense these officers of the later Roman empire days came as close to the modern sense of professional leaders as it was known until the French Revolution.

The feudal period knew no general, long-service military profession and as a result had no officers of the modern stamp. Each nobleman had his serfs for military duties in the short-lived campaigns of the dark ages and the early middle ages. The main business of the knights in the feudal age was to earn their livelihood by overseeing the tilling of their lands. The 40 days of service which the serfs owed their lords prevented warfare from being more than a desultory occupation and in no way qualified the feudal nobles as officers in a professional military system. Furthermore, the obligation to the lord above him was not for regular service but rather an "on call" service.

The professionalization of war appeared in the 15th century when free companies of Swiss, Italian and German soldiers sold their services by company wherever they were needed. These mercenary troops were a thoroughly international class and their captains, both able leaders of men and freebooters. They made a business of fighting, contracting with various princes or dukes for so much professional service; they earned their livelihood by warring, and in a way their captains qualified as the first officers in the modern sense.

Their mercenary business passed out of existence about the middle of the 17th century when the dynastic standing armies came into being. Free companies had been responsible for the designations of rank in the lower grades of officers, particularly that of captain.

17th and 18th Centuries.—Before the period was reached in the 18th century when kings obtained their forces by recruitment and paid them, there existed for a time, after feudalism and free companies became obsolete, a proprietary system. In effect the colonel was the proprietor of the regiment formed by himself, and the captain the proprietor of his company. This practice continued even after the kings formed their standing armies and was common in the United States in the Revolutionary War. General George Washington, as commander in chief, was accepted by the militia of the various colonies even though the latter were made up of elected officers whose authority and position stemmed largely from the fact that they had brought so many men in an organized form to become freely a part of their state militia, and as such, a legal portion of the larger forces of the united colonies.

The proprietary system gave to military office not only responsibilities, but also certain profits. The officer, particularly in European armies, was paid for the number of men that he mustered and was furnished other funds for their arms and food. As a result commissions became of great value, particularly in Britain. As late as 1871, commissions had to be purchased in the British army, the cost of a second lieutenancy of infantry being about a year's pay or approximately $2,000. The purchase of the commission of a lieutenant colonel in a first-class regiment might cost as much as $30,000 in Britain. Besides the profit in the discharge of proprietary rights, the officer could sell his proprietary interest when he retired.

To return for the moment to the Thirty Years' War of the 17th century, there was a great development of the grades or ranks of regimental officers in the well-organized army of Gustavus Adolphus. He established the idea of the regiment with its colonel, and the battalion commanded by a lieutenant colonel, assisted by a major as the administrative chief and by an additional officer, a captain who arranged for supplies. The companies were commanded by captains as a continuation of the free company method, while the subordinate officers in the unit were lieutenants.

The general terminology for the grades of regimental officers having been established, it remained largely for the French to develop during the next century the ranks of the higher positions, above the grade of colonel.

Usually the king or prince was the "general" of a standing army, being supported by a nobleman as lieutenant general in command of the aristocratic cavalry. A professional officer usually commanded the infantry and was variously known as the "sergeant major general" or simply "major general." It was his duty to form the army for battle, and to take care of other administrative matters for the king or prince. The title of sergeant major was carried through the regiments and battalions where the second-in-command was the sergeant major or "major," and adjutant as well. The regimental sergeant major was usually drawn from among the best qualified lieutenants and not from among the proprietary captains of companies.

A new title gradually came into being in the French army, that of "marshal" or "field marshal." These titles were given regardless of the actual command which the officer held—the reverse of the usual practice of that period. For in the 16th century, the general and major general were the commanders of a particular army, and each of the subordinates was a captain

or lieutenant of a particular regiment. As a result the officers, other than the marshals, were tied to a specific army or unit. When the unit was disbanded, they lost their positions, thus being required either to find a vacancy and become a member of another regiment or to retire.

In France, the introduction of the distinctive military grade of marshal brought about the gradual development of a list of all officers by order of rank, the list encompassing officers through the regimental grades until it became the army list common in modern times. Thus the proprietary system was gradually undermined until it passed out of existence in the 18th century. Marshals were at first any and all officers of grade higher than colonel and were eligible for appointment as generals, lieutenant generals, and major generals. Gustavus Adolphus had six or eight field marshals as subordinate generals. However, as armies grew larger and their operations took place over greater areas, more subordinate commanders were needed. In time, a lieutenant general, which had been the designation for the second-in-command of an army, was placed in the rank immediately below that of marshal. The next grade was that of the *maréchal-de-camp,* the sergeant major general, or as it was shortened, the major general. The lowest grade of general officer was that of brigadier, created by Louis XIV.

French Revolution to Mid-20th Century.—During this period the most significant development was that officer status was gradually opened to qualified soldiers in the ranks. Significantly, too, officer status was not limited to combat commanders but opened to a great number of technical positions unknown in warfare before the industrial revolution: for instance, the officer whose sole job was to supervise the production of guns, the man who piloted an aeroplane. As a result the numbers of officers in modern armies grew out of all proportion to that known in previous wars. In World War II, the combined United States army and air force had almost 900,000 officers. The total included the small, prewar regular corps of approximately 14,000 officers, a reserve group of just over 100,000, the remainder being commissioned from the ranks, or directly from civil life.

In the British army, officers normally were paid so little that only persons of some wealth could afford to seek commissions. The custom in many well-to-do British families was for the older sons to become clergymen and officers in the army and navy, leaving business and agriculture to the younger sons. It was not until 1938 that the British government opened up its officer grades to the rank and file of English youth, both from inside and outside the services. The reforms were sweeping and did away with such disabilities as the low pay which required augmentation from personal income, and also eliminated the inactive status during which a regular officer had sometimes found himself on half pay. Consequently, the British army officer class became more representative of the nation as a whole, merit determining promotion. Even the social barriers were broken down so that service as a British officer more closely paralleled that in the U.S. army than it did that in the German army.

In Germany there developed a military society which elevated war to a position of glory. Army officers were drawn from German citizens with a college education, 60% of the regular army officers having been reservists on active service who were recommended by their colonels. The remainder were commissioned upon graduation from cadet schools. Candidates for commissions not only had to qualify themselves militarily but also had to be acceptable to all other officers in the regiment, much as if they were being elected to an exclusive club or fraternity. Because the German system of universal liability made every physically able man an officer or enlisted soldier, there developed the regular and reserve officer classifications as an integral part of German society. Compulsory military service combined with the mobilization requirements made it the ambition of young men to become army or navy officers. The entire system was strongly supported by the landholding aristocracy, who made certain that members of their group, the *Junkers,* rose to high command and staff positions in the army. The arrogance of the Prussian officer was communicated to the rest of the German army, giving it a false sense of officer evaluation which often put form and an exaggerated military bearing above knowledge and ability. Efficiency in a mechanical vein was one of the fetishes of the Prussian officer caste, detracting from the human qualities so essential in the making of good officers in democratic armies.

The French nobility had largely been eliminated from influential military positions in the Napoleonic era. Men who might never have been more than sergeants in the armies of Louis XIV rose to field marshals under Napoleon. Against this background, the selection of officers in France during the 19th century was probably more democratic than in any other nation. Two schools were maintained for the training of officers, the majority of the candidates gaining admission from civil life through competitive examinations. Noncommissioned officers in the regular army were also eligible to compete for cadetships. Throughout the 19th century and to the mid-20th century, French officers were well schooled and able men, though officer positions declined in standing mainly because of the low pay and the fact that men of wealth were rarely attracted to service including stations in overseas colonies.

In the far east the Japanese army was largely officered by the nobility. Descendants of the traditional samurai class generally attained highest rank in both command and staff in the Japanese army. A certain similarity developed between Germany and Japan in the rise of a military society in which the officers became the high priests. Japanese officers developed much of the same arrogance and patronizing airs not uncommon in the German army of the 19th century.

Russia, under the tzars, gave officer status almost entirely to the nobility. The position was often more social than military and provided many plots for Russian literature. Upon the bolshevist revolution, Vladimir Lenin created an army from the proletariat, taking his leaders from among labourers and revolutionists.

During the interim between the World Wars I and II the soviet army developed slowly, with special attention paid to raising the military to a position of the élite among the soviet hierarchy. In World War II, the initial commanders were the leaders of the old bolshevist forces, men like Klementiy Voroshilov, Semyon Timoshenko, and the Cossack leader, Simeon Budenny. They were not quite up to the demands of modern warfare, except in defensive combat, and gave way to younger officers when the Red army turned to the offensive. The new officers had been trained in the various military district schools and had demonstrated their leadership on the battlefield. Many women became officers in the Soviet army and took their place on an equal basis with the men.

Officers in the U.S. army continued to represent a cross section of the population and were obtained by varied systems of selection. During the Revolutionary War, men ignorant of military affairs became officers through political influence. Massachusetts offered a captaincy to any man who raised a company of 59 men, and a colonel's commission to anyone who raised ten such companies. The evils of the system were great since history mentions companies electing captains on the condition that they share their pay with the other men. The story is told that one captain acted as the barber for his company. The experience of the Revolutionary War was duplicated to a smaller degree in the Civil War when governors of states appointed officers in the volunteer forces, often without regard to their experience. Many of the small nucleus of regular officers who had been trained at the U.S. Military academy got their chance in the war by obtaining volunteer appointments from state governors at ranks far beyond the permanent ones they held. The experience of General Philip Sheridan, who fought as a captain in the regular army for a full year before he was elevated to a colonelcy of volunteers, was common among the regulars.

After a similar experience in the Spanish-American War, the U.S. made a strong effort in both World Wars I and II to select and promote officers on the basis of merit. In these wars, positions in the higher command and staff were given most often to regular officers, while the other grades were filled with civilians brought into uniform, many of whom had military duties almost

identical with their civilian work. U.S. practice through all its wars was democratic in that it was possible for a man from any walk of life to rise to high command. However, a man of some prominence admittedly had a better chance to obtain a commission than his less influential fellow man.

Historically, the development of the officer position was pertinent to only armies and navies until World War I, at which time the air officer, usually a pilot, was added to the commissioned officer group. Commissioned air officers were formed into a coequal service, the air force, in Britain and Germany between the World Wars I and II, but were maintained as part of the army in other major nations until after the close of World War II, when the soviet and the U.S. air forces became separate entities.

GRADES OF ARMY AND AIR FORCE OFFICERS

General Officer Grades.—In the period after World War II, the general grades (ranks being of enlisted men) of officers were as follows:

Field Marshal.—In the soviet army, the term applied not only to Stalin as commander in chief but also to several of his highest ranking field commanders. In the soviet army the rank was not given to any particular arm, such as infantry, but generally denoted the command of an army or more often a group of armies. In Britain, the chief of the imperial general staff and the top field commanders, without regard to arm of the service, were given this title. In France, the term *maréchal* was an honorary title in recognition of long and outstanding service by a general officer.

General of the Army.—This title was created in the United States after World War II, and conferred by the congress on several high commanders, such as Generals Dwight D. Eisenhower and Douglas MacArthur. The precedent had been established after World War I when General John J. Pershing was given the title "general of the armies."

General.—This grade is normally identified with the commander of a field army, though it was also used for occasional high staff positions. This was the rank which Gen. George C. Marshall held throughout the war and which was conferred on Gen. Omar Bradley as the commander of an army group near the end of the war.

Lieutenant General.—This title is generally used in all the major armies except the French for the commander of a corps of two or more divisions. The relative rank in France is *général-de-corps.*

Major General.—The commander of a division in war or peace or the commander of a military district is given this rank in practically all armies of the world. In France the designation is *général-de-division.* Also most of the high general staff positions are given this rank, and only rarely is a higher rank given for any staff officer other than the chief of staff of a theatre command.

Brigadier General.—This term comes from the position of the commander of two regiments, when organized as a brigade. Though that organization had disappeared at mid-20th century, except in the British army, the term was still used in most armies to designate the second-in-command of a division, the commander of the divisional artillery, or the commander of a task force comprising a number of combined arms. In Britain the term is brigadier; in France, *général-de-brigade;* and in the U.S., brigadier general. The soviet army did not adopt the term brigadier.

Air force officers in most countries followed the same general system of ranking their higher commanders, though in Britain the royal air force gave its high commanders the titles of: Marshal of the royal air force (equivalent to field marshal); air chief marshal (general); air marshal (lieutenant general); and air vice-marshal (major general). For the brigadier grade, the British royal air force borrowed from the navy and utilized the title air commodore.

Field Officer Grades.—The second large grouping of officers, below the general officers in seniority, is the field officers, comprising the ranks of colonel through major. In France this group is known as the *officiers supérieurs.* The field officers are as follows:

Colonel.—A grade denoting the commander of a regiment in all armies of the world with the exception of the British, which has no infantry regiments. However, the title was adopted as an honorary one in the British service and during World War II was given increasingly to staff officers who occupied staff positions comparable to those of U.S. colonels.

Lieutenant Colonel.—In practically all armies at mid-20th century the commander of a battalion of infantry, cavalry or tanks, second-in-command in a regiment, and the grade of the majority of officers on the general staff was lieutenant colonel.

Major.—In many of the armies, the major as second-in-command of a battalion had acquired some of the functions of the historical sergeant major. In the U.S. and soviet armies, the major practically never commands a combat unit though in the French army the major, called a commandant, often commands a battalion, while in Great Britain the junior majors sometimes command companies.

In the U.S., U.S.S.R. and France, where the air force had been a part of the army for a longer period than in countries like Britain, the titles for field officers became identical for both the air and ground force officers. The British equivalents were group captain for colonel, wing commander for lieutenant colonel, and squadron leader for major.

Company Officer Grades.—The third grouping of officers is the company grade, which in France is called *subaltern.* The grades are as follows:

Captain.—In all armies, commander of an infantry company, the title which goes back through the days of the proprietary and mercenary companies.

Lieutenant.—In the U.S., this officer is known as a first lieutenant, and in Belgium the platoon chief, which is indicative of the office he often holds. The lieutenant may, however, be second-in-command of a company in all armies except the British, where a captain is second-in-command to a major when the latter commands a company.

Second Lieutenant.—This officer is usually a platoon commander and is known by this title in most armies, except in France where he is called *sous-lieutenant.*

Aspirants or Cadets.—Practically all armies have young officers on a probationary status who reach commissioned status when they have satisfactorily completed their military studies.

Again, as with field grade officers, the same company officer grades are given to air as well as ground officers. The British, however, give a captain the title flight lieutenant, the lieutenant is called flying officer, and the second lieutenant, pilot officer.

SOURCE OF OFFICER MATERIAL

Frederick the Great and Napoleon set the standard of military academy education as a primary method of obtaining officers for the regular army. In Great Britain, France, the United States, and the U.S.S.R., this method of obtaining a commission requires completion of schooling and competitive examinations before a commission is granted. Military academies are open generally to youths between the ages of 17 and 22 years of age. The curricula feature a general military education. One of the invariable requirements for entrance is that the candidates be unmarried.

Entry into the air officer status is attained also through cadet air training schools. Air academies were slow to arise, as a supplement to military academies, because of the late attainment of equal status by the air force. Moreover, in the desire to make officers mutually cognizant of the responsibilities of the army, navy and air force in their co-operative aims, the suggestion was made that military academies might be utilized as post-graduate schools for all three armed forces. Their candidates would be drawn from civilian colleges, or from the enlisted ranks, a minimum educational equivalent being required. The system of selection for the various military academies is briefly explained below.

U. S. Officer Candidates.—Officers in the United States army have been obtained from three different sources: from graduates of the United States Military academy; from graduates of

civilian colleges, either by direct commission or by competitive tours of one year; and from among reserve officers up to the age of 45, by integration on the basis of equivalent years of service. Both the navy and air force have obtained their regular officer complement from the same sources, except that the navy has its own Naval academy, and the air force obtains officers from the Naval as well as the Military academy.

Army and air force officer candidates are educated at the U.S. Military academy, West Point, N.Y., and for the naval and air services, at the U.S. Naval academy, Annapolis, Md. The student body for both schools is filled by congressional appointments, each congressman at mid-20th century being given four appointments for West Point, and five for Annapolis. Selection of cadets is by competitive examination, for which may be substituted successful completion of the college board tests given to preparatory school students, or better-than-average grades in previous college work. The president has a number of appointments, often used for sons of deceased veterans, and the regular services and the national guard also were given rights of appointments—open to all enlisted men on a competitive basis. However, most of the students at the academies have not had previous military service.

Both schools offer a typical, four-year, college curriculum at government expense, leading to a bachelor of science degree. Supplementing the academic subjects are courses in military and naval matters. The objective of the schools is to produce officers who have the qualities and character essential to their continuing development as leaders. The academies generally seek to implant a high sense of duty and patriotism, while assuring mental and physical fitness.

Upon the successful completion of the four-year course, the graduate is commissioned a second lieutenant in the army or air force, or an ensign in the navy. At mid-20th century West Point and Annapolis had not furnished even a majority of regular officers in the services, since far larger numbers had been commissioned from U.S. colleges, or had been inducted from the reserve officer group.

British Officer Candidates.—Great Britain, on the other hand, has obtained practically all its regular officers from its military schools. Medical and legal officers have of necessity been obtained from graduates of civilian universities. Prior to World War II, Britain maintained two cadet schools: the Royal Military college at Sandhurst; and the Royal Military academy at Woolwich. Sandhurst was a school for officers of the infantry, tank corps and other line elements, while Woolwich trained artillery, engineer and signal officers.

Prior to 1938, entry into these schools was confined almost solely to the sons of upper-class citizens, though a few cadetships were open to noncommissioned officers from the ranks. The reform of 1938 made it possible for an English youth who was successfully qualified to obtain military training at government expense. Assurance of a secure career after graduation was given to all cadets. These two schools had a two-year course and were open to men 18 years of age. Both schools differed considerably from the U.S. Military academy in that emphasis was upon military training, no effort being made to obtain for the cadets a college degree. These two schools furnished about three-fourths of the total number of regular officers, the remainder coming from graduates of colleges, from the army, and from the commonwealth nations.

In the post-World War II period, Sandhurst and Woolwich were consolidated into a single Royal Military academy, located at Sandhurst.

French Officer Candidates.—Like the British, the French maintained two schools for candidates for commissions in the French army: École Spéciale Militaire at St. Cyr and École Polytechnique in Paris. Again like the British military schools, they featured a two-year course. St. Cyr, like Sandhurst, trained men for the infantry and the tanks, while Polytechnique, like Woolwich, trained technical men for the engineers, artillery, and other services. Candidates for both schools at mid-20th century had to be between the ages of 18 and 22 years, of French citizenship, and unmarried. Most of the cadets w of civilian origin and obtained their admission through co petitive examination. Both schools also maintained a cert number of noncommissioned officers selected from the regu army as candidates for commissions. Their educational standa were high. only the most brilliant students in the nation bei able to qualify for admission to the Polytechnique school. The was no board or tuition, the cadet being paid by the governme as in the U.S. The course of instruction in the schools w a blend of the academic and military. These two schools h furnished most of the regular officers in the French army.

Soviet Officer Candidates.—Prior to World War II t U.S.S.R. had no cadet schools for military commissions simil to those of western nations. However, in each of the military districts there were infantry schools and sometim artillery schools for the training of candidates for commission Schools for the other branches were concentrated in Europea Russia, but usually there was only one school for each branch.

Candidates entering the schools were required to be betwee the ages of 17 and 21, after having served from one to thre years in the Red army, or having been graduated with distinctio from a high school. Competition was keen for vacancies an the calibre of the cadets quite high. The curricula for the schoo were normally two years of higher education, including som military tactics and history, and the third year given ove primarily to military training. While the graduates undoubted had less academic education than cadets of the western nation they were well grounded militarily and had a basic intensity o purpose which compensated for some of their lack of education After World War II military education in the soviet army an air force was greatly expanded, a number of new schools bein opened, all of them named after Russian heroes.

OFFICER TRAINING

All modern armies lay great stress upon the training of officers World War II experience was proof that the tactical and staff schools paid great dividends. Moreover, the method of training an officer in alternative troop command and school assignments during his early career, and in alternative staff, command, school and instruction of reserve officer groups, in his later career, proved eminently satisfactory.

Most important, officers tend to serve for much longer periods than enlisted men, their careers measuring 30 or 40 years. Preparedness for defense of the country is their primary objective, though defense in modern warfare includes requirements for commanders, staff officers and technical specialists.

Because peacetime experience can never duplicate that of war, what is learned in the normal officer duties is insufficient to produce the calibre of officers needed in war when officers are promoted quickly through several ranks. In peace, seniority is the rule; in war, promotion is based largely on merit. Because experience in peacetime becomes outdated, and because it does not adequately fit the officer for wartime demands, the essential requirement is training. Officers are schooled in the theories of tactics and strategy and in the principles of war. Flexibility of mind is the goal in military education. However, this usually means trained minds, not learned ones. An officer who is mentally competent, a student of warfare, and a man of action is preferable in the hard necessities of the military art to an academic-minded officer who sees too many imponderables, and is therefore hesitant to act.

The army officer recently graduated from a military academy is usually given two or three years in command of a platoon of soldiers to acquaint him with the problems of leadership and to impress upon him the necessity of knowing the small-unit tactics as they apply to soldiers in the ranks. Moreover, in such experience, the young officer is physically capable of accomplishing each soldier's job, so that he can show a rifleman or machine gunner how to handle his weapon. After a period of command, the officer may go to the school of his arm, such as infantry or artillery, to obtain a basic knowledge of its tactics and techniques. In some armies, this training of the early years

is reversed on the theory that the junior officer is better qualified to command men if he has had the benefit of tactical schooling. Other than this difference, however, the training of officers seems to run to a pattern. The sequence includes service in the military academy, command, basic school of his arm, command, advanced school of his arm, command, staff college, staff assignment, war college and the remainder of his career either command or staff, whichever field seems best to suit the individual.

It is understandable that much of his training is concentrated on learning tactics and staff procedures by application so that the individual is able to do them practically blindfolded. This is not to say that schooling is unthinking nor that it is adjusted to the unintelligent but rather that it is based upon the requirements of service. Most officers have occasion during their careers to train younger regular officers and reservists. Close adherence to military doctrine is the surest guarantee of obtaining the best trained men.

United States.—Officer training in the U.S. army and air force at mid-20th century included schooling at regular intervals throughout the first 20 years of service. Every officer looked forward to attending both basic and advance courses in his infantry, artillery or tank school. In addition he would have had alternate command assignments, so that by the time he was a major he would have proceeded through the company commands and thus be prepared for training at the staff college. There the emphasis was upon staff procedures and the functions of the staff, rather than upon tactics. The officer-student was concerned with the work of each staff section in divisions, corps, and armies. Subsequently a U.S. army or air officer was usually assigned to duty in a city with the reserve corps or national guard, or in a university with the reserve officers' training corps. Later he might expect duty on the general staff, and about the time of promotion to a colonelcy to become a student at the War college, if in the upper few percent of his contemporary group.

During the first ten years officers who began their service in the infantry or artillery might have become specialists in ordnance, signal communications, engineering and the like. Some of them were eventually transferred to those branches, with further training in civilian schools and universities and at the Industrial college.

Great Britain.—The British army officer at mid-century, like the American, entered into the duties of platoon commanding a short time after he was commissioned. He was expected after two years of service to be capable of commanding a company, to have a knowledge of its interior management, conomy, and discipline. Subsequently, he was required to pass professional examinations at each step up to and including the rank of lieutenant colonel. Advanced training in the British army included certain outside activities such as the reading of articles on military science and attendance at special lectures arranged by the higher commands. By such methods, including examinations, officers were kept abreast of the development of modern combat methods. Eventually, selected officers were sent to staff colleges such as Camberly. After graduation they would be eligible for employment on the staff, either the general staff or a divisional staff. Above the Staff college was the Imperial General Staff college, an equivalent of the National War college in the U.S., where colonels and brigadiers study political-military problems, similar to those which confront the high command in peace and war.

France.—The French training system was the model upon which both British and U.S. training had been developed. Great emphasis was placed upon qualification both in education and military training. Education was continuously and progressively brought to each officer; his training was developed at schools for specialists and at the school of each arm.

The staff college, École Supérieure de Guerre, was designed to teach the higher art of war as opposed to a pure study of staff duties. The school was open at mid-century to French officers between the ages of 28 and 38, after which there was another course at the War college for colonels at about age 45.

Soviet Union.—Officers of the Red army at mid-century were trained at branch service schools, much as in the western democracies. Also the more capable officers were sent to staff schools and eventually to the War college. The pattern of development in the soviet army gave great emphasis to two items: political beliefs of the individual, and his ability to command troops. There was an increasing amount of specialization, efforts being made to teach officers transportation, engineering, and other technical specialties needed both in the army and in industrial life.

THE OFFICERS' SERVICE

While training requirements were somewhat fixed for officers in all armies, there were great differentiations in the kind of duty they performed when not in school, and the places where they served. The usual expectancy in every army was that officers would command troops from one-fourth to one-half of their careers. However, this requirement was constantly lowered in the 20th century because of the complexity of war, which increased the demands for staff officers and technical specialists.

Once having left a command and having entered into either staff or technical work, the officer may still have contact with the soldiers of the army, but the relationship is never the same as in the command of a company or battalion of troops. The spirit of unity, the *esprit de corps,* of the line outfit is never quite achieved in other fields where the individual is thinking of his paper work or interested in science. However, the latter two fields are necessary parts of a modern army and the staff officer must quickly learn the functions of personnel, intelligence, plans, operations, training or supply. In each field, the knowledge that he brings with him of the men in ranks assists him in determining whether his policy on paper can be carried out by men. In the general staff field, many of the problems extend into the field of political-military affairs and grand strategy. The training of the ordinary officer is not sufficient to equip him adequately for this requirement. Consequently such jobs are assigned to officers who have maintained a lively interest in world affairs and have attained a sense of proportion regarding them.

The third grouping of duties for officers is the technical or supply services. The capable technical officer may possibly be a graduate of an engineering school, as well as a graduate of a military academy. His work in signal communication, ordnance, or procurement of supplies, will bring him into constant contact with business and industrial men. Mutual understanding by these groups is essential since they have the task of rapid industrial mobilization in the event of war.

The high command in most armies is normally given to the line officer, with a background in infantry, artillery, or tanks, who has alternated his command experience with general staff duties. These officers will in time have taken a very divergent path from those of the technical experts, qualifying themselves more as executives and administrators in the later years of their service, rather than as specialists in technical fields.

The duties of officers in all countries require a certain amount of overseas service, in colonies, occupation of conquered countries, or in strategic outposts. Accordingly the officer is alternately moving from an army post to an overseas garrison or militia units. The duties are varied and in many cases stimulated by new interests and new places.

Discipline.—Not only must the officer be disciplined in his own mind and body, but he must also have an understanding of the disciplinary customs of his own people serving in the armed forces. The Prussian system of unthinking obedience from mechanical soldiers is not attuned to the requirements of the democracies, or to the needs of modern warfare.

Machine weapons compelled the troops to disperse on the battlefield. In the isolation of the individual soldier in his foxhole, there was an incessant demand for the moral and physical courage which only an understanding system of discipline could foster.

Officers to be successful leaders must associate themselves with the troops. Diligence in the care of the men in ranks, resolute justice, creative intelligence, respect for the dignity of

the position of other soldiers are essential. Knowledge of the military art, flexibility, and all the other requirements of leadership are undermined if the officer does not understand the human aspect of dealing with fellow men over whom he holds a position of power. The object of the relationship between officer and soldier is the strengthening of the will of the latter. Only when the enlisted man is so motivated will he take voluntary actions on the battlefield, which in the aggregate are the difference between victory and defeat. The officer-leader stands or falls in the decision of those rare moments when the result is in the hands of the men he has trained and lived with.

Methods of Promotion.—In modern armies, four methods of promotion within the officer grades have been utilized—election, selection by merit, competitive examination and seniority. The second and fourth means—selection and seniority—are the most commonly used methods of advancing officers in grade. The system of selection varies considerably in all armies but must be construed in the narrow sense. For instance, most selection systems require a certain seniority before an individual can be pushed forward ahead of his contemporaries. Also the requirements for selection in years of service may be expanded or decreased to pull out the number of officers it is desired to promote. In times of peace, when vacancies are few, the service requirements for promotion may be increased. Seniority in a promotion system has its good and bad points. It is usually confined to the grades of colonel or less, generals often being selected without strict regard to seniority.

In peacetime, promotion is normally a permanent advancement while in wartime tremendous expansion is usually handled by temporary promotion, regular officers retaining, simultaneously, a permanent grade. In World War II, there were many cases of permanent captains who held the rank of brigadier and even major general, though rapid advancement was more common in the air force than in the army.

One method of determining whether promotions are earned is by a qualification report. This is a normal requirement in all armies, though administered differently. In the U.S. army such reports, known as "efficiency reports," were submitted annually at mid-century for lieutenant colonels and those of higher rank, but semiannually for all other officers. The report was prepared by the immediate senior of the officer named, and indorsed by the next higher senior, before being forwarded to the department of the army. The reports were evaluated by modern electrographic means, and each report given a rating. The average of an officer's rating over a period of years determined largely whether he would qualify for the Staff and War colleges.

The British and soviet armies utilized a system of promotion which included temporary advances on the basis of service, and other promotions which were a perquisite of a certain assignment. During World War II, a hypothetical British captain might have held a temporary, or substantive, grade of lieutenant colonel, and a position grade of colonel. When he vacated the latter assignment, he reverted to his substantive grade.

CONCLUSION

Officers in a modern army, air force, or navy, have a responsible task. The lives of many of the nation's citizens depend upon their integrity, judgment and knowledge. Probably in no other field of endeavour are leaders thrust so quickly into positions of great responsibility as officers are in time of war. The competence of his training and character are, in part, the responsibility of his peacetime superiors. That charge on senior officers is difficult to meet, because war's realities cannot be fully comprehended, particularly as they pertain to the training and development of a single subordinate officer.

The complexity of modern war is reflected in the requirements on the officer. Not only must he study the usual academic subjects and his military tactics, but also psychology, leadership and scientific subjects. From his inner knowledge, he must be able to tell the modern soldier what is expected of him, and to discuss with him why he fights. The tremendous developments in modern weapons compelled troops to disperse on the battlefield; if the lone soldier armed with a rocket launcher is to do his part in battle, his commanding officer must have laid the groundwork long before the day of battle. The soldier must be confident in his leadership, know for what he is fighting, and know how to fight. The demands upon officers are therefore not only military and educational but also reach down into the social nature of mankind. To be a good officer he must understand men, and know how to get the most out of them in a spirit of co-operation rather than by driving.

The officer is the product of his own nation's social system. But his colleagues in other armies share the difficulties of the increasing complexity of modern warfare. It is said that an infantry officer must know how to fire 20 weapons. When he is promoted from company to field grade, he is expected to know the capabilities and limitations of artillery, tanks and of support aircraft. For in combined warfare, the officer commanding a battalion or regiment must know what are reasonable and what are impossible demands upon other arms and services. These two facts—the complexity of modern war and the equality of all men in uniform—are never-ending problems which the capable officer will realize that he must study constantly, knowing full well that complete understanding is an unattainable goal.

OFFICIAL SECRETS. At common law there was, and is, no such offense as espionage in time of peace. In time of war, however, the act of communicating information useful to an enemy state was always punishable under the head of treason. In 1889, by the first Official Secrets act this gap in the law was filled by making it a felony to obtain or communicate any "sketch," information, or "document" concerning the country's defenses which "might be useful to an enemy" for "any purpose prejudicial to the safety of the state." This very necessary statute was, however, almost completely diverted from its original purpose by successive acts of 1911 and 1920, into a statute for the better protection of the bureaucracy against well-informed criticism. Entirely new sections were introduced making it an offense, punishable with two years' hard labour, for anyone who has ever served the crown to communicate to "any person" any "information" whether prejudicial to the state or not which he has acquired in his official capacity. It is sufficient for a conviction that the "information" was acquired when the person communicating it was serving the crown and the accused is not allowed to plead, or prove, that publication was "in the public interest." Truth is also no defense; it is, in fact, essential to a conviction. If the accused can prove that the "information" he communicated was false, he will be acquitted. Any person connected with a newspaper, director, editor or leader-writer, receiving the information is also liable to conviction. It is unnecessary for the prosecution to prove *mens rea* (guilty intent), on the part of such recipient. Search warrants may be issued, for the purpose of such prosecution, by any superior police officer without the usual authorization of a magistrate; any newspaper office may be raided and any member of the staff who refuses, or omits, to give information to the police is guilty of a statutory offense. These extraordinary departures from the rules of law prevailing in England are the result of these statutes and their interpretation in *Rex* v. *Crisp and Homewood*, 83 J. p. 121, and *Rex* v. *Blake* (Times Law Report, Dec. 16, 1926). The acts have been the subject of deservedly severe criticism, and the Newspaper Proprietors association agitated for their drastic amendment. (J. H. Mo.)

OFFSET, a term expressing the distance between two parallel planes, or between two parallel axles in a machine; also used in plumbing work to describe a connection between a large and a

small pipe, in which the opening of the smaller pipe is eccentrically placed, so that the axes of the pipes, although parallel, are not in the same line. In architecture, an offset is a slanting plane, forming a transition between a thin wall above and a thick wall below, or between varying depths of a buttress; an offset buttress is one deeper at the bottom than at the top, with the difference between the upper and lower faces taken up by one or more offsets.

OFFSET PRINTING: *see* PRINTING.

OGASAWARA-JIMA (BONIN ISLANDS, OGASAWARA-SHOTO, OGASAWARA-GUNTO), a group of about 20 small islands, 27 sq.mi. in area, lying about 500 mi. S.E. of the Japanese mainland. The population was about 7,500 in 1940; in 1950 only one island was inhabited (pop. 146). The principal island is Chichi-Jima (Peel Island), which is of some strategic importance, having a good deep-water anchorage at Futami. Eastern Asia is fringed by island arcs, the innermost consisting of the large islands of Japan, Formosa and the Philippines, and the outermost of small islands alone. The Ogasawara islands form part of one outer festoon which stretches from the central volcanic zone of Japan through the Volcano, Mariana, Mackenzie, Yap and Palau Islands to the Moluccas and which, originating in the latter stages of the "alpine" fold movements, is still unstable. The northern end of the arc passes into central Honshu, that part of Japan where earthquakes are most frequent, and in the Ogasawara group tiny islands appear and disappear. The arc has an important strategic position with regard to the Pacific approaches of the far east.

Although known to several explorers, each of whom gave the group a different name, these islands, originally called Bonin, were not permanently settled until 1830. The term "Bonin" is a corruption of the Japanese "Munin" meaning "empty of men," but the Japanese themselves term them "Ogasawara-Gunto" after Ogasawara, their alleged discoverer in 1593. Vague claims by Britain and the United States were not pursued, and Japan formally annexed them in 1876. Only about 11% of the total area is good arable land, the remainder being hilly and forest-covered. The valuable timber includes cedar, rosewood, ironwood, boxwood, sandal and white oak.

After World War II the Ogasawara Islands were placed under U.S. military administration. Under the peace treaty signed at San Francisco, Calif., on Sept. 8, 1951, Japan agreed to accept any U.S. proposals to place the Ogasawara Islands under trusteeship of the United Nations.

OGDEN, a city of Utah, U.S.A., 35 mi. N. of Salt Lake City, at the confluence of the Ogden and the Weber rivers and the foot of the Wasatch mountains; the county seat of Weber county and the second city of the state in size. It is on federal highways 30S, 89 and 91 and is served by the Denver and Rio Grande Western, the Southern Pacific, the Oregon Short Line, the Union Pacific and the Bamberger electric railways; also by United and Western air lines. The population was 57,112 in 1950, 43,688 in 1940 and 40,272 in 1930 by the federal census.

Ogden lies 4,310 ft. above sea level on an alluvial fan or semicircular delta, formed under the waters of the ancient Lake Bonneville. Mt. Ogden (9,685 ft. high), from which the entire shoreline of the ancient lake, covering 19,750 sq.mi., may be clearly seen, and Ben Lomond (9,985 ft. high) rise abruptly on the east and north, and between them the Ogden river makes its way through one of the most picturesque canyons in America. In a broad valley 10 mi. up the canyon, Pine View dam created Pine View lake, impounding 44,000 sq.ft. of water. This water is used primarily for irrigation, although it serves recreationally for boating, swimming and fishing. Immediately south of this reservoir, accessible by a paved highway, is Snow Basin, a 6,000-ac. area for summer and winter sports, serviced by ski lifts, shelters and other facilities.

The city's manufacturing and industries are important; chief among them are flour milling, meat packing, vegetable canning, candy, tin cans, cement, dairy and ice cream products, boxes and crates, knitted goods and custom-tailored clothing. Ogden serves as the marketing centre for the livestock of the intermountain west. More livestock are handled annually through the Ogden Union Stockyards than at any other point west of Colorado. The annual Ogden livestock show is held there.

Ogden was settled by the Mormons in 1847, was laid out under the direction of Brigham Young in 1850 and was incorporated in 1851.

The first official name was Brownsville, but it was changed in honour of the trapper Peter Skene Ogden, who had located there in 1826. The northern end of the city was a grassy meadow, where the Indians met for games and races and to trade with the white men.

OGDENSBURG, a city of St. Lawrence county, N.Y., U.S., on the St. Lawrence river at the mouth of the Oswegatchie, 50 mi. from Lake Ontario. It is served by the New York Central and the Rutland railways and lake and river steamers, and is connected by passenger and car ferry with the Canadian Pacific and the Grand Trunk railways at Prescott, Ont., on the opposite bank of the St. Lawrence.

The population of Ogdensburg in 1950 was 16,166; by the federal census of 1940 it was 16,346.

The city lies on high ground above the river, which is a mile wide there. It has a fine harbour, open throughout the year, and is an important shipping and transfer point, especially for lumber, grain and coal.

With the completion of the Welland canal in 1930 it became accessible to the largest lake vessels. Ogdensburg is a port of entry and headquarters of the St. Lawrence customs district. The city's manufactures include shade rollers, paper and pulp, office supplies, matches and containers.

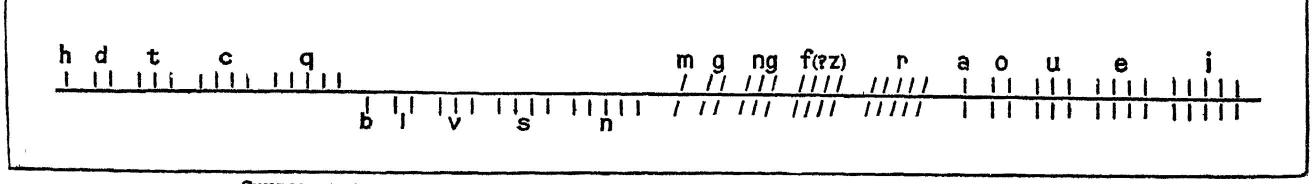
Ogdensburg is the seat of a state hospital for the insane; a state armory; and the Remington Art memorial, containing the collection of Indian relics and many of the paintings and statuettes of Frederic Remington, who was born in Canton, the county seat. The Thousand Islands of the St. Lawrence lie about 30 mi. S.W.

Ogdensburg was the site of the Indian settlement of La Présentation, founded in 1749 by the Abbé François Picquet for converted Iroquois, and of Fort Presentation, built by the British at the outbreak of the Revolution and held by them until 1796. The settlement that grew up about the fort was named after Abraham Ogden (1743–98), a New Jersey lawyer who bought land there. During the early part of the War of 1812 it was an important point on the American line of defense, and on Feb. 22, 1813, both fort and village were captured and partly destroyed by the British.

Ogdensburg was incorporated as a village in 1817 and as a city in 1868.

OGEE, in architecture, a curve of double curvature, concave below and convex above. Thus an ogee arch is a pointed arch in which each side has an ogee curve; also applied to the moulding (*q.v.*) more commonly known as a *cyma reversa.*

OGHAM LANGUAGE. The language of the Ogham inscriptions is the oldest form of Goidelic with which we are acquainted. Some 300 inscriptions have been discovered in this alphabet, the majority of them hailing from the southwest of Ireland (Kerry and Cork). In Scotland 22 are known, while in Eng-



SYMBOLS OF THE OGHAM ALPHABET, ORIGINALLY USED BY THE CELTS IN BRITAIN AND IRELAND

land and Wales about 30 have turned up. Most of the latter are in south Wales, but odd ones have been found in north Wales, Devon and Cornwall, and one occurs in Hampshire. The Isle of Man possesses two. The letters in the oldest inscriptions are formed by strokes or notches scored on either side of the edge of an upright stone. Thus we obtain the alphabet on the preceding page.

This system, which was eked out with other signs, would seem to have been framed in the southwest of Ireland by a person or persons who were familiar with the Latin alphabet. Some of the inscriptions probably go back to the 5th century and may even be earlier. The simplest forms of Ogham inscriptions are: *Doveti maqqi Cattini, i.e.* "(the stone) of Dovetos son of Cattinos"; *Trenagusu Maqi Maqi-Treni* is rendered in Latin *Trenegussi Fili Macutreni hic jacit; Sagramni Maqi Cunatami,* "(the stone) of Sagramnos son of Cunotamos"; *Ovanos avi Ivacattos,* "(the stone) of Ovanus descendant of Ivacattus."

In the oldest of these inscriptions *q* is still kept apart from *k* (*c*), and the final syllables have not disappeared (cf. *maqqi,* O.Ir. *maicc*); but it appears certain that in Oghamic writing stereotyped forms were used long after they had disappeared in ordinary speech. Several stones contain bilingual inscriptions, but the key to the Ogham alphabet is supplied by a treatise on Oghamic writing contained in the Book of Ballymote, a manuscript of the late 14th century.

See R. R. Brash, *The Ogham Inscribed Monuments of the Gaedhil* (1879); R. A. Stewart Macalister, *Studies in Irish Epigraphy,* 3 vols. (1897–1907), and *Archaeology of Ireland* (1928). Welsh inscriptions are given in J. Rhys, *Lectures on Welsh Philology* (1879). The Scottish stones have also been treated by Rhys in the *Proceedings of the Scottish Society of Antiquaries* (Edinburgh, 1892). *See* also G. M. Atkinson for the tract in the Book of Ballymote, *Kilkenny Journal of Archaeology* (1874). The Irish Christian inscriptions were published by Margaret Stokes as the annual volumes of the Roy. Hist. and Archaeol. Association of Ireland (1870–77), and have been republished by R. A. Stewart Macalister.

OGIER THE DANE, a hero of romance, identified with the Frankish warrior Autchar (Autgarius, Auctarius, Otgarius, Oggerius) of the old chroniclers. In 771 or 772 Autchar accompanied Gerberga, widow of Carloman, Charlemagne's brother, and her children to the court of Desiderius, king of the Lombards, with whom he marched against Rome. In 773 he submitted to Charles at Verona.

He finally entered the cloister of St. Faro at Meaux, and Mabillon (*Acta SS ord. St. Benedicti,* Paris, 1677) left a description of his monument there, which had figures of Ogier and his friend Benedict or Benoît, with smaller images of Roland and La Belle Aude and other Carolingian personages. In the chronicle the *Pseudo-Turpin* it is stated that innumerable *cantilenae* were current on the subject of Ogier, and his deeds were probably sung in German as well as in French. The Ogier of romance may be definitely associated with the flight of Gerberga and her children to Lombardy, but it is not safe to assume that the other scattered references all relate to the same individual. Colour is lent to the theory of his Bavarian origin by the fact that he, with Duke Naimes of Bavaria, led the Bavarian contingent to battle at Roncevaux.

In the romances of the Carolingian cycle he is, on account of his revolt against Charlemagne, placed in the family of Doon de Mayence, being the son of Gaufrey de "Dannemarche." The *Enfances Ogier* of Adenès le Rois, and the *Chevalerie Ogier de Dannemarche* of Raimbert de Paris, are doubtless based on earlier chansons. The *Chevalerie* is divided into 12 songs or branches. Ogier, who was the hostage for his father at Charlemagne's court, fell into disgrace, but regained the emperor's favour by his exploits in Italy. One Easter at the court of Laon, however, his son Balduinet was slain by Charlemagne's son, Charlot, with a chessboard (cf. the incident of Renaud and Bertholais in the *Quatre Fils Aymon*). Ogier in his rage slew the queen's nephew Loher, and would have slain Charlemagne himself but for the timely intervention of the knights, who connived at his flight to Lombardy. In his stronghold of Castelfort he resisted the imperial forces for seven years, but was at last taken prisoner by Turpin, who incarcerated him at Reims, while his horse Broiefort, the sharer of his exploits, was made to draw stones at Meaux. He was eventually released to fight the Saracen chief Bréhus or Braihier, whose armies had ravaged France, and who had defied Charlemagne to single combat. Ogier consented to fight only after the surrender of Charlot, but the prince was saved from his barbarous vengeance by the intervention of St. Michael. The giant Bréhus, despite his 17 ft. of stature, was overthrown, and Ogier, after marrying an English princess, the daughter of Angart (or Edgard), king of England, received from Charlemagne the fiefs of Hainut and Brabant.

A later romance in Alexandrines (Brit. Mus. MS Royal 15 E vi) contains marvels added from Celtic romance. Six fairies visit his cradle, the sixth, Morgan le Fay, promising that he shall be her lover. He has a conqueror's career in the east, and after 200 years in the "castle" of Avalon returns to France in the days of King Philip, bearing a firebrand on which his life depends. This he destroys when Philip's widowed queen wishes to marry him, and he is again carried off by Morgan le Fay. The prose romance printed at Paris in 1498 is a version of this later poem.

The fairy element is prominent in the Italian legend of *Uggieri il Danese,* the most famous redaction being the prose *Libro dele bataglie del Danese* (Milan, 1498), and in the English *Famous and renowned history of Morvine, son to Oger the Dane,* translated by J. M. (London, 1612).

The Spanish Urgel was the hero of Lope de Vega's play, the *Marques de Mantua.* Ogier occupies the third branch of the Scandinavian Karlamagnus saga; his fight with Brunamont (*Enfances Ogier*) was the subject of a Danish folk song; and as *Holger Danske* he became a Danish national hero, who fought against the German Dietrich of Bern (Theodoric "of Verona"), and was invested with the common tradition of the king who sleeps in a mountain ready to awaken at need. Whether he had originally anything to do with Denmark seems doubtful. The surname le Danois has been explained as a corruption of l'Ardennois and Dannemarche as the marches of the Ardennes.

OGILBY, JOHN (1600–1676), British writer, was born in or near Edinburgh in Nov. 1600. He accompanied Thomas Wentworth, earl of Strafford, when he went to Ireland as lord deputy, and became tutor to his children. Strafford made him deputy-master of the revels, and he built a little theatre in St. Werburgh Street, Dublin, which was very successful. The outbreak of the Civil War ruined his fortunes, and in 1646 he returned to England. Finding his way to Cambridge, he learned Latin from kindly scholars who had been impressed by his industry. He then ventured to translate Virgil into English verse (1649–50), which brought him a considerable sum of money. Ogilby learned Greek from David Whitford, who was usher in the school kept by James Shirley the dramatist. *Homer his Iliads translated . . .* appeared in 1660, and in 1665 *Homer his Odysses translated . . .* Anthony à Wood asserts that in these undertakings he had the assistance of Shirley. At the Restoration Ogilby received a commission for the "poetical part" of the coronation. His property was destroyed in the great fire of 1666, but he rebuilt his house in Whitefriars, and set up a printing press, from which he issued many magnificent books; the most important were a series of atlases by Hollar and others. He died in London on Sept. 4, 1676.

Ogilby also translated the fables of Aesop, and wrote three epic poems. His bulky output was ridiculed by John Dryden in *MacFlecknoe* and by Alexander Pope in the *Dunciad.*

OGILVIE (or OGILBY), **JOHN** (*c.* 1580–1615), English Jesuit, was born in Scotland and educated mainly in Germany, where he entered the Society of Jesus, being ordained priest at Paris in 1613. As an emissary of the society he returned to Scotland in this year disguised as a soldier, and in Oct. 1614 he was

arrested in Glasgow. He defended himself stoutly when he was tried in Edinburgh, but he was condemned to death and was hanged on Feb. 28, 1615.

A True Relation of the Proceedings against John Ogilvie, a Jesuit (Edinburgh, 1615), is usually attributed to Archbishop Spottiswoode. *See* also James Forbes, *L'Église catholique en Ecosse: martyre de Jean Ogilvie* (Paris, 1885); and W. Forbes-Leith, *Narratives of Scottish Catholics* (1885).

OGILVY, the name of a celebrated Scottish family of which the earl of Airlie is the head. The family was probably descended from a certain Gillebride, earl of Angus, who received lands from William the Lion. Sir Walter Ogilvy (d. 1440) of Lintrathen, lord high treasurer of Scotland from 1425 to 1431, was the son of Sir Walter Ogilvy of Wester Powrie and Auchterhouse, a man, says Andrew of Wyntoun, "stout and manfull, bauld and wycht," who was killed in 1392. Sir Walter built a castle at Airlie in Forfarshire, and left two sons. The elder of these, Sir John Ogilvy (d. *c.* 1484), was the father of Sir James Ogilvy (*c.* 1430–*c.* 1504), who was made a lord of parliament in 1491; and the younger, Sir Walter Ogilvy, was the ancestor of the earls of Findlater. The earldom of Findlater, bestowed on James Ogilvy, Lord Ogilvy of Deskford, in 1638, was united in 1711 with the earldom of Seafield and became dormant after the death of James Ogilvy, the 7th earl, in Oct. 1811.

Sir James Ogilvy's descendant, James Ogilvy, 5th Lord Ogilvy of Airlie (*c.* 1541–1606), a son of James Ogilvy, master of Ogilvy, who was killed at the battle of Pinkie in 1547, took a leading part in Scottish politics during the reigns of Mary and of James VI. His grandson, James Ogilvy (*c.* 1593–1666), was created earl of Airlie by Charles I at York in 1639. A loyal partisan of the king, he joined Montrose in Scotland in 1644 and was one of the royalist leaders at the battle of Kilsyth. The destruction of the earl's castles of Airlie and of Forther in 1640 by the earl of Argyll, who "left him not in all his lands a cock to crow day," gave rise to the song "The bonny house o'Airlie." His eldest son, James, the 2nd earl (*c.* 1615–*c.* 1704), also fought among the royalists in Scotland; in 1644 he was taken prisoner, but he was released in the following year as a consequence of Montrose's victory at Kilsyth. He was again a prisoner after the battle of Philiphaugh and was sentenced to death in 1646, but he escaped from his captivity at St. Andrews and was afterward pardoned. Serving with the Scots against Cromwell he became a prisoner for the third time in 1651, and was in the Tower of London during most of the years of the Commonwealth. He was a fairly prominent man under Charles II and James II, and in 1689 he ranged himself on the side of William of Orange. This earl's grandson, James Ogilvy (d. 1731), took part in the Jacobite rising of 1715 and was attainted; consequently on his father's death in 1717 he was not allowed to succeed to the earldom, although he was pardoned in 1725. When he died his brother John (d. 1761) became earl *de jure,* and John's son David (1725–1803) joined the standard of Prince Charles Edward in 1745. He was attainted, and after the defeat of the prince at Culloden escaped to Norway and Sweden, afterward serving in the French army, where he commanded *le régiment Ogilvy* and was known as *le bel Ecossais.* In 1778 he was pardoned and was allowed to return to Scotland, and his family became extinct when his son David died unmarried in April 1812. After this event David's cousin, another David Ogilvy (1785–1849), claimed the earldom. He asserted that he was unaffected by the two attainders, but the house of lords decided that these barred his succession; however, in 1826 the attainders were reversed by act of parliament and David became 6th earl of Airlie. He died on Aug. 20, 1849, and was succeeded by his son, David Graham Drummond Ogilvy (1826–81), who was a Scottish representative peer for more than 30 years.

The latter's son, David William Stanley Ogilvy, the 8th earl (1856–1900), served in Egypt in 1882 and 1885, and was killed on June 11, 1900, during the Boer War while at the head of his regiment, the 12th Lancers. His titles then passed to his son, David Lyulph Gore Wolseley Ogilvy, the 9th earl (b. 1893).

A word may be said about other noteworthy members of the Ogilvy family. John Ogilvy, called Powrie Ogilvy, was a political adventurer who professed to serve King James VI as a spy and who certainly served William Cecil in this capacity. Mariota Ogilvy (d. 1575) was the mistress of Cardinal Beaton. Sir George Ogilvy (d. 1663), a supporter of Charles I during the struggle with the Covenanters, was created a peer as lord of Banff in 1642; this dignity became dormant, or extinct, on the death of his descendant, William Ogilvy, the 8th lord, in June 1803. Sir George Ogilvy of Barras (d. *c.* 1679) defended Dunnottar castle against Cromwell in 1651 and 1652, and was instrumental in preventing the regalia of Scotland from falling into his hands; in 1660 he was created a baronet, the title becoming extinct in 1837.

See Sir R. Douglas, *Peerage of Scotland,* new ed. by Sir J. B. Paul (1904 fol.).

OGIVE, in architecture, the diagonal ribs of a Gothic vault; in French usage applied to any pointed arch. As a result Gothic architecture is frequently termed in France *le style ogival.*

OGLESBY, a city of La Salle county, Illinois, U.S.A., 100 mi. S.W. of Chicago, on the Illinois river at the mouth of the Vermilion, opposite La Salle and Peru. It is on federal highway 51, and is served by the Chicago, Milwaukee, St. Paul and Pacific and the Illinois Central railways. Pop. (1950) 3,922; (1940) 3,938 by federal census.

It is part of a tri-city industrial district, engaged chiefly in the manufacture of cement and coal mining. There are extensive deposits of limestone. The city was founded in 1856 and incorporated in 1902. Until 1913 it was called Portland.

OGLETHORPE, JAMES EDWARD (1696–1785), English general and philanthropist, the founder of the state of Georgia, was born in London on Dec. 21, 1696, the son of Sir Theophilus Oglethorpe (1650–1702) of Westbrook Place, Godalming, Surrey. He entered Corpus Christi college, Oxford, in 1714, but in the same year joined the army of Prince Eugène. He became aide-de-camp to the prince, and served in the campaign against the Turks, 1716–17, more especially at the siege and capture of Belgrade. After his return to England he was in 1722 elected member of parliament. With the idea of providing an asylum for persons who had become insolvent, and for oppressed Protestants on the continent, he projected the settlement of a colony in America between Carolina and Florida (*see* GEORGIA). In 1745 Oglethorpe was promoted to the rank of major-general. His conduct in connection with the Scottish rebellion of that year was the subject of a court-martial, but he was acquitted. In 1765 he was breveted general. He died at Cranham Hall, Essex, in 1785.

Sir Theophilus Oglethorpe, the father, had four sons and four daughters, James Edward being the youngest son, and another James having died in infancy. Of the daughters, Anne Henrietta, Eleanor and Frances Charlotte (Bolingbroke's "Fanny Oglethorpe") may be specified as having played rather curious parts in the Jacobitism of their time; their careers are described in the essay on "Queen Oglethorpe" by Miss A. Shield and A. Lang, in the latter's *Historical Mysteries* (1904). *See* also Lives by Harris (1841), Wright (1867), Bruce (1890), and Harriet C. Cooper (1904).

OGOOUÉ, a river of west central Africa, about 750 mi. long, rising in 3° S. in the highlands known as the Crystal range, and flowing northwest and west, reaches the Gabun coast of the Atlantic by Cape Lopez, a little south of the equator. There it forms a considerable delta. In its upper course the Ogooué is much obstructed by rapids as it descends the successive steps of the tablelands. It breaks through the outer chains of the mountainous zone, between 10¾° E. and 11¾° E. In its lower course the river passes through a lacustrine region in which it sends off secondary channels. These channels, before reuniting with the main stream, traverse a series of lakes, one north, the other south, of the river. These lakes are natural regulators of the river when in flood. Of its tributaries the chief are the Lolo, which joins on the south bank in 12° 20′ E., and the Ivindo, which enters the Ogooué a few miles lower down. Below the Ivindo the largest tributaries are the Ofooué, 400 yd. wide at its mouth (11° 47′ E.), but unnavigable except in the rains, and the Ngunye, the largest southern tributary, navigable for 60 mi. to the Samba or Eugénie falls. Apart from the narrow coast plain the whole region of the lower Ogooué is densely forested and the predominant industry of the region is the timber trade. The fauna includes the gorilla and chimpanzee.

The Ogooué rises in March and April, and again in October and November; it is navigable for steamers at low water as far as the junction of the Ngunye, and at flood time for a distance of 235 mi. to N'Jole. The first person to explore the valley of the Ogooué was Paul du Chaillu, who travelled in the country during 1857–59. The Ogooué lies wholly in French Equatorial Africa (*q.v.*).

For a vivid account of life on the lower Ogooué *see* A. Schweitzer, *On the Edge of the Primeval Forest* (1922).

O'GRADY, STANDISH JAMES (1846–1928), Irish man of letters, was born at Castletown, County Cork, on Sept. 18, 1846, the son of a Protestant clergyman, studied at Trinity college, Dublin, and after taking his degree in 1868 was called to the bar in 1872. He died at Shanklin, Isle of Wight, on May 18, 1928. O'Grady was one of the pioneers of the Celtic renaissance in Ireland. His interest in Irish antiquities was roused by the reading of O'Halloran's *History of Ireland,* and he set himself to awaken living interest in the Irish past by telling over again the Irish legends of the heroic age. He himself believed in the historical existence of the heroes of Irish epic, being convinced that primitive singers could not have invented them. His first work, *History of Ireland: the Heroic Period* (Dublin, 1878), was republished, in part, under the title of *Cuculain: an Epic,* in London (1882), and was succeeded by *History of Ireland: Cuculain and his Contemporaries* (Dublin, 1880). From these he developed his cycle of romantic histories: *Finn and his Companions* (1892), *The Coming of Cuculain* (1894), *In the Gates of the North* (Kilkenny, 1901), and the *Passing of Cuculain* (Dublin, 1917). He began a *History of Ireland, Critical and Philosophical,* of which the first volume only was written (Dublin, 1881). He also wrote *Ulrick the Ready* (1896); *The Bog of Stars* (1893); *Red Hugh's Captivity* (1889).

See Standish O'Grady, *Selected Essays and Passages* (Dublin, 1918).

OGRE, the name in fairy tales and folklore of a malignant monstrous giant who lives on human flesh. The word is French, and occurs first in Charles Perrault's *Histoires ou contes du temps passé* (1697). The first English use was in the translation of a French version of the *Arabian Nights* in 1713, where it was spelled *hogre.* Attempts have been made to connect the word with *Ugri,* the racial name of the Magyars or Hungarians, but it is generally accepted that it was adapted into French from the O. Span. *huerco, huergo, uergo,* cognate with Ital. *orco* (*i.e., Orcus*), the Latin god of the dead and the infernal regions (*see* PLUTO), who in Romance folklore became a man-eating demon of the woods.

OGYGES or **OGYGUS,** in Greek mythology, the first king of Thebes. During his reign came a great deluge (*see* DEUCALION); this is one of the two Greek versions of the widespread flood-legend. Ogyges is variously described as a Boeotian autochthon, as the son of Cadmus, or of Poseidon.

O'HAGAN, THOMAS O'HAGAN, 1ST BARON (1812–1885), lord chancellor of Ireland, was born at Belfast on May 29, 1812. He was educated at Belfast Academical institution, and was called to the Irish bar in 1836. In 1850 he removed to Dublin, where he appeared for the repeal party in many political trials.

His advocacy of a continuance of the union with England, and his appointment as solicitor general for Ireland in 1861 and attorney general in the following year, lost him the support of the Nationalist party, but he was returned to parliament as member for Tralee in 1863. In 1865 he was appointed a judge of common pleas, and in 1868 became lord chancellor of Ireland in Gladstone's first ministry.

He was the first Roman Catholic to hold the chancellorship since the reign of James II, an act throwing open the office to Roman Catholics having been passed in 1867. In 1870 he was raised to the peerage, and held office until the resignation of the ministry in 1874. In 1880 he again became lord chancellor on Gladstone's return to office, but resigned in 1881. He died in London on Feb. 1, 1885, and was succeeded by his eldest son, Thomas Towneley (1878–1900), and then by another son, Maurice Herbert Towneley (b. 1882).

O'HARA, THEODORE (1820–1867), U.S. lawyer, soldier, journalist and poet, was born Feb. 11, 1820. He served with distinction in the U.S. army in 1846–48 during the Mexican War, took part in the filibustering expeditions to Cuba, and was with the Confederate army during the U.S. Civil War. He wrote the well-known poem "The Bivouac of the Dead," in memory of soldiers who died at the battle of Buena Vista.

O'HIGGINS, BERNARDO (1776–1842), one of the foremost leaders in the Chilean struggle for independence and head of the first permanent national government, was a natural son of the Irishman Ambrosio O'Higgins, governor of Chile (1788–95), and was born at Chillán on Aug. 20, 1776. He was educated in England, and after a visit to Spain he returned to Chile in 1802 where he lived quietly on his estate until the revolution broke out in 1810.

Joining the nationalist party led by Martínez de Rozas, he distinguished himself in the early fighting against the royalist troops despatched from Peru, and was appointed in Nov. 1813 to supersede J. M. Carrera in command of the patriot forces. The rivalry that ensued, in spite of O'Higgins' generous offer to serve under Carrera, eventually resulted in O'Higgins being isolated and overwhelmed with the bulk of the Chilean forces at Rancagua in Oct. 1814.

O'Higgins with most of the patriots fled across the Andes to Mendoza, where José de San Martín (*q.v.*) was preparing a force for the liberation of Chile and Peru. San Martín espoused O'Higgins' part against Carrera, and O'Higgins, recognizing the superior ability and experience of San Martín, readily consented to serve as his subordinate. The loyalty and energy with which he acted under San Martín contributed not a little to the organization of the liberating army, to its transportation over the Andes, and to the defeat of the royalists at Chacabuco (Feb. 1817) and Maipú (April 1818).

After the battle of Chacabuco O'Higgins was entrusted with the administration of Chile, and he ruled the country firmly and well, maintaining close connection with Argentina, co-operating loyally with San Martín in the preparation of the force for the invasion of Peru, and seeking, as far as the confusion and embarrassments of the time allowed, to improve the welfare of the people. After the overthrow of the Spanish supremacy in Peru had freed the Chileans from fear of attack, an agitation set in for constitutional government. O'Higgins at first tried to maintain his position by calling a congress and obtaining a constitution (1822) which invested him with dictatorial powers. But popular discontent grew in force; risings took place in Concepción and Coquimbo, and on Jan. 28, 1823, O'Higgins resigned his post of director general, without attempting to retain it by force. He retired to Peru, where he was granted an estate and lived quietly till his death on Oct. 24, 1842. In 1839 the Chilean senate restored him to his honours and his military rank.

See B. Vicuña Machenna, *Vida de O'Higgins* (Santiago, 1882), and M. L. Armunàtegni, *La Dictadura de O'Higgins* (Santiago, 1853); both containing good accounts of O'Higgins' career. Also P. B. Figueroa, *Diccionario biográfico de Chile, 1550–1887* (Santiago, 1888), and J. B. Suarez, *Rasgos biográficos de hombres notables de Chile* (Valparaiso, 1886).

O'HIGGINS, KEVIN CHRISTOPHER (1892–1927), Irish statesman, youngest son of Dr. T. Higgins (who was murdered by unknown men in 1923), of Stradbally, Queen's county, was born in 1892 at Stradbally and educated at Clongowes and St. Patrick's college, Carlow, and in the National University of Ireland. He was articled to his uncle Maurice Healy, a solicitor in Cork. After the Easter rebellion in 1916 he joined the Sinn Fein movement, and was interned. While still in jail he was elected member for Queen's county (1918). He acted as assistant minister for local government to Mr. Cosgrave, and in 1922 became a member of the provisional government as minister of justice and vice president of the executive council. As minister of justice he established the civic guard, and put down disorder with a strong hand. He was called to the Irish bar in 1923, and in June 1927 added to his existing duties those of minister for external affairs.

In the midst of the controversy with De Valera over the taking

of the oath in the Dail he was waylaid by three armed men while on his way to mass at Booterstown, outside Dublin, and shot dead (July 10, 1927). It was believed that the crime was connected with the fact that, as minister of justice, O'Higgins had been largely responsible for the 77 executions which were carried out in the course of the civil war. He married Bridget Mary Cole, of Dublin, in 1921, who, with the two children of the marriage, survived him.

O'HIGGINS, an inland province of central Chile, bounded north by Santiago, east by Argentina, and south and west by Colchagua. Area, 2,746 sq.mi.; population (1950), 212,492. Named after Bernardo O'Higgins, the first president of the republic of Chile, the province was included with that of Colchagua from 1928 to 1933, inclusive. Most of the western half of the province lies in the central valley of Chile, whose surface is interrupted in many places by the alluvial piedmont slopes of the Andes and the transverse valleys of perennial streams which have their sources in the snow-capped summits of the cordillera. The climate of the western part of the province is typically Mediterranean, with summers that are hot and rainless, and winters that are mild and rainy. Eastward the climate reflects the control of increasing altitude; temperatures are lower, rainfall is heavier and much of the precipitation which falls in the winter is in the form of snow. The streams which give life to the central valley during the long, dry summer are fed by the melting snows of the high Andes. Under irrigation the valley lands are highly productive, although only a small fraction of the total area is under cultivation.

The principal crops on irrigated lands are wheat, corn, barley, oats, alfalfa, clover, legumes and grapes; the bulk of the non-irrigated land is pasturage having a low carrying capacity. Mining is carried on in the eastern highlands, the province being widely known for its production of copper.

Rancagua, the capital of the province (population 31,018 in 1940), is in central O'Higgins, 51 mi. south of the nation's capital on the State railways. Rengo, the second largest city (6,730 in 1940), is about 20 mi. S.S.W. of Rancagua. Both cities are centres of commerce for the surrounding agricultural districts. The province is particularly noted for its hot springs and mineral waters, and many popular health resorts are within relatively short distances from the capital. Termas de Cauquenes (Cauquenes hot springs), significant in the history of the emancipation of Chile, and the most important centre of mineral waters in the country, is slightly more than 80 mi. by car E.S.E. from Rancagua. Also famous are the mineral waters of El Teniente and Baños de Cachantun, the latter being only 15 mi. from the provincial capital. (R. W. Rd.)

O'HIGINN, TADHG DALL (O'Higgin, Teague) (*d.* 1616), Irish poet, also known in Irish writings as Tadhg dall Ua hUiginn, was born at Magh Nenda, the plain between the rivers Erne and Drobhais on the southern boundary of Ulster. He was blind most of his life, and this accounts for his Irish sobriquet "dall."

O'Higinn advocated Irish nationalism in his poems, exhorting the Irish to unite their nations or clans and resist the English. His earliest extant poem was written before 1554. It was a work of 50 stanzas written to Eoghan óg MacSuibhne na dtuath to urge him to make friends with Shane O'Neill and Manus O'Donnell. He wrote a 52-verse panegyric on the O'Neills in 1573 entitled "Imda sochar ag cloinn Neill" ("Many the privileges belonging to the children of Niall"). He praised the residence of Shane O'Neill in a poem "Lios greine as Emhain dUlltaibh" ("A sunny fort is an Emania to Ulstermen"). In this poem he compared it to Emhain Macha, or Emania, which was the residence of the ancient kings of Ulster.

About 1588 he wrote an address of 70 stanzas to Sir Brian na Murtha O'Rourke advising him to take the offensive against the English. Between 1566 and 1589 he wrote a 39-stanza poem "Mairg fhechus ar inischeithleann" ("Woe for him that looks on Enniskillen").

His last poem was "Sluagseisir tainic dom thig" ("A band of six men came into my house"). This was a satire on the six O'Haras who looted his house. A translation by S. H. O'Grady was printed with the original poem. O'Higinn died shortly before 1617.

OHIO, popularly known as the "Buckeye state," is a north central state of the United States of America, lying approximately between 38° 25′ and 41° 58′ N. and 80° 31′ and 84° 49′ W. It is bounded north by Michigan and Lake Erie, east by Pennsylvania and by the Ohio river, which separates it from West Virginia, south by the Ohio river which separates it from West Virginia and Kentucky and west by Indiana. The state is nearly square in shape, its extremes from north to south and from east to west being about 210 mi. and 220 mi. respectively. The total area is 41,222 sq.mi., of which 222 sq.mi. are inland water surface.

Physical Features.—The state lies on the borderland between the prairie plains and the Allegheny plateau. The disturbances among the underlying rocks of Ohio have been slight, and originally the surface was a plain only slightly undulating; stream dissection changed the region to one of numberless hills and valleys; glacial drift then filled up the valleys over large broken areas, forming the remarkably level till plains of northwestern Ohio; but at the same time other areas were broken by the uneven distribution of the drift, and southeastern Ohio, which was unglaciated, retains its rugged hilly character, gradually merging with the typical plateau country farther southeast. The average elevation of the state above the sea is about 850 ft. but extremes vary from 425 ft. at the confluence of the Great Miami and Ohio rivers in the southwest corner, to 1,550 ft. on the summit of Hogues hill about 1½ mi. E. of Bellefontaine in the west central part.

The main water parting is formed by a range of hills which are composed chiefly of drift and extend west-southwest across the state from Trumbull county in the northeast to Drake county, or about the middle of the west border. North of this water parting the rivers flow into Lake Erie; south of it into the Ohio river. Passing the village of Cuyahoga Falls the Cuyahoga river descends more than 200 ft. in 3 mi.; a part of its course is between walls of sandstone 100 ft. or more in height, and near its mouth, at Cleveland, its bed has been cut down through 60 ft. of drift.

In the middle north part of the state the Black, Vermilion and Huron rivers have their sources in swamps on the water parting and flow directly to the lake through narrow valleys. The till plains of northwestern Ohio are drained chiefly by the Maumee and Sandusky rivers, with their tributaries.

In the southwest the Great Miami and Little Miami rivers have uniform falls through basins that are decidedly rolling and contain the extremes of elevation for the state. The central and south middle part is drained by the Scioto river and its tributaries. Its basin is about 40 mi. wide and only moderately rolling, but toward the mouth of the river the basin becomes narrow and is shut in by high hills. In the eastern part of Ohio the Muskingum river and its tributaries drain an area of about 7,750 sq.mi. or nearly one-fifth of the entire state. The Ohio flows for 436 mi. through a narrow valley on the southern border of the state, and Lake Erie forms the northern boundary for a distance of 230 mi. At the west end of the lake are Sandusky and Maumee bays, each with a good natural harbour. There are several small lakes on the water parting, especially in the vicinity of Akron and Canton.

Fauna and Flora.—Opossums, skunks and raccoons are plentiful in some parts of the state, and rabbits and squirrels are still numerous.

Most of the songbirds and birds of prey of the temperate zone are plentiful. Whitefish, bass, trout and pickerel are important as food from the waters of Lake Erie, and the land streams and lakes are stocked with game fish.

Ohio is known as the "Buckeye state" from the prevalence of the buckeye chestnut (*Aesculus glabra*). The state was originally covered with a dense forest mostly of hardwood timber, and although the merchantable portion of this has been almost entirely cut away, there are still undergrowths of young timber and a great variety of trees. The white oak is the most common, but there are 13 other varieties of oak, 6 of hickory, 5 of ash, 5 of poplar, 5 of pine, 3 of elm, 3 of birch, 2 of locust and 2 of cherry.

Beech, black walnut, butternut, chestnut, catalpa, hemlock and tamarack trees are also common. Wild flowers are well represented. Of native ferns there are many.

Climate.—The mean annual temperature of Ohio is about 51° F.; in the north 49.5° and in the south 53.5°. But except where influenced by Lake Erie the temperature is subject to great extremes; at Coalton, Jackson county, in the southeast part of the state, the highest recorded range of extremes is from 104° F. to −38°, or 142°; at Wauseon, Fulton county, near the northwest corner, it is from 104° to −32°, or 136°; while at Toledo, on the lake shore, the range is only from 99° to −16°, or 115°. July is the warmest month, and in most parts of the state January is the coldest; in a few valleys, however, February has a colder record than January. The normal annual precipitation for the entire state is about 39 in. It is greatest in the southeast and least in the northwest. At Marietta, for example, it is 42.1 in., but at Toledo it is only 30.8 in. The prevailing winds in most parts are westerly, but sudden changes, as well as the extremes of temperature, are caused mainly by the frequent shifting of the wind between northwest and southwest.

Soil.—In the driftless area, the southeast part of the state, the soil is largely a decomposition of the underlying rocks, and its fertility varies according to their composition; there is considerable limestone in the east central portion, and this renders the soil very productive. In the valleys also are strips covered with a fertile alluvial deposit. In the other parts of the state the soil is composed mainly of glacial drift, and is generally deep and fertile. It is deeper and more fertile, however, in the basins of the Great Miami and Little Miami rivers, where there is a liberal mixture of decomposed limestone and where extensive areas with a clay subsoil are covered with alluvial deposits.

History.—Ohio was the pioneer state of the old Northwest territory, which embraced also what are now the states of Indiana, Illinois, Michigan and Wisconsin and the northeast corner of Minnesota. When explored by Europeans, late in the first half of the 17th century, the territory included within what is now Ohio was a battleground of Indian tribes. From the middle to the close of the 17th century the French were establishing a claim to the territory between the Great Lakes and the Ohio river by discovery and occupation.

About 1730 English traders from Pennsylvania and Virginia began to visit the eastern and southern parts of the territory and a conflict approached as a French Canadian expedition under Céleron de Bienville took formal possession of the upper Ohio valley by planting leaden plates at the mouths of the principal streams. This was in 1749 and in the same year George II chartered the first Ohio company, formed by Virginians and London merchants trading with Virginia, for the purpose of colonizing the west. This company, in 1750, sent Christopher Gist down the Ohio river to explore the country as far as the mouth of the Scioto river, and four years later the erection of a fort was begun in its interest at the forks of the Ohio. The French drove the English away and completed the fort (Fort Duquesne) for themselves. The Seven Years' War ensued, and this ended in the cession of the entire northwest to Great Britain. The former Indian allies of the French, however, immediately rose up in opposition to British rule in what is known as the conspiracy of Pontiac (*see* PONTIAC), and the suppression of this was not completed until Col. Henry Bouquet made an expedition (1764) into the valley of the Muskingum and there brought the Shawnees, Wyandots and Delawares to terms. With the northwest won from the French, Great Britain no longer recognized those claims of its colonies to this territory which Great Britain had asserted against France, but in a royal proclamation of Oct. 7, 1763, the granting of land west of the Alleghenies was forbidden and on June 22, 1774, parliament passed the Quebec act which annexed the region to the province of Quebec. This was one of the grievances which brought on the Revolutionary War, during which the northwest was won for the Americans by George Rogers Clark (*q.v.*). During that war also, those states which had no claims in the west contended that title of these western lands should pass to the union and when the Articles of Confederation were submitted for ratification in 1777, Maryland refused to ratify them except on that condition. The result was that New York ceded its claim to the United States in 1780, Virginia in 1784, Massachusetts in 1785 and Connecticut in 1786. Connecticut, however, excepted a strip bordering on Lake Erie for 120 mi. and containing 3,250,000 ac. This district, known as the Western Reserve, was ceded in 1800 on condition that congress would guarantee the titles to land already granted by the state. Virginia reserved a tract between the Little Miami and Scioto rivers, known as the Virginia Military district, for its soldiers in the Revolutionary War. When the war was over and these cessions had been made, a great number of war veterans wished an opportunity to repair their broken fortunes in the west, and congress, hopeful of receiving a large revenue from the sale of lands there, passed an ordinance on May 20, 1785, by which the modern national system of land surveys into townships 6 mi. square was inaugurated in what is now southwest Ohio in the summer of 1786. In March 1786 the second Ohio company (*q.v.*), composed chiefly of New England officers and soldiers, was organized in Boston, Mass., with a view to founding a new state between Lake Erie and the Ohio river. The famous Northwest ordinance was passed by congress on July 13, 1787. This instrument provided a temporary government for the territory with the understanding that, as soon as the population was sufficient, the representative system should be adopted, and later that states should be formed and admitted into the union. There were to be not less than three nor more than five states.

On the adoption of the Northwest ordinance the work of settlement made rapid progress. There were four main centres. The Ohio company founded Marietta at the mouth of the Muskingum in 1788, and this is regarded as the oldest permanent settlement in the state. An association of New Jersey people, organized by John Cleves Symmes, secured a grant from congress in 1788–92 to a strip of 248,540 ac. on the Ohio, between the Great Miami and the Little Miami, which came to be known as the Symmes Purchase. Their chief settlements were Columbia (1788) and Cincinnati (1789). The Virginia Military district, between the Scioto and the Little Miami, reserved in 1784 for bounties to Virginia continental troops, was colonized in large measure by people from that state. Their chief towns were Massieville, now Manchester (1790), and Chillicothe (1796). A small company of Connecticut people under Moses Cleaveland founded Cleveland in 1796 and Youngstown was begun a few years later, but that portion of the state made very slow progress until after the opening of the Ohio and Erie canal in 1832.

During the territorial period (1787–1803), Ohio was first a part of the unorganized Northwest territory (1787–99), then a part of the organized Northwest territory (1799–1800) and later the organized Northwest territory (1800–03) from which Indiana territory had been detached on the west in 1800. The first territorial government was established at Marietta in July 1788, and Gen. Arthur St. Clair, the governor, arrived in that month. His administration was characterized by the final struggle with the Indians. The Revolutionary War was succeeded by a series of Indian uprisings. Two campaigns, the first under Gen. Josiah Harmar (1753–1813) in 1790 and the second under General St. Clair in 1791, failed on account of bad management and ignorance of Indian methods of warfare, and in 1793 Gen. Anthony Wayne (*q.v.*) was sent out in command of a large force of regulars and volunteers. The decisive conflict, fought on Aug. 20, 1794, near the rapids of the Maumee, is called the battle of Fallen Timbers, because the Indians concealed themselves behind the trunks of trees which had been felled by a storm. Wayne's dragoons broke through the brushwood, attacked the left flank of the Indians and soon put them to flight. In the treaty of Greenville (Aug. 3, 1795) the Indians ceded their claims to the territory east and south of the Cuyahoga, the Tuscarawas, and an irregular line from Fort Laurens (Bolivar) in Tuscarawas county to Fort Recovery in Mercer county, practically the whole of eastern and southern Ohio. The Jay treaty was ratified in the same year, and in 1796 the British finally evacuated Detroit and the Maumee and Sandusky forts. By cessions and purchase in 1804, 1808 and 1817–18, the state secured all the lands of the Indians except

their immediate homes, and these were finally exchanged for territory west of the Mississippi. The last remnant migrated in 1841. General Wayne's victory was followed by an extensive immigration of New Englanders, of Germans, Scotch-Irish and Quakers from Pennsylvania and of settlers from Virginia and Kentucky, many of whom came to escape the evils of slavery. This rapid increase of population led to the establishment of the organized territorial government in 1799, and to the admission of the state into the union in 1803.

The congressional Enabling act of April 30, 1802, followed that alternative of the Northwest ordinance which provided for five states in determining the boundaries, and in consequence the Indiana and Michigan districts were detached. A rigid adherence to the boundary authorized in 1787, however, would have resulted in the loss to Ohio of 470 sq.mi. of territory in the northwestern part of the state, including the lake port of Toledo. After a long and bitter dispute—the Toledo War (*see* TOLEDO)—the present line, which is several miles north of the south bend of Lake Michigan, was definitely fixed in 1837, when Michigan came into the union. (For the settlement of the eastern boundary, *see* PENNSYLVANIA.) After having been temporarily at Marietta, Cincinnati, Chillicothe and Zanesville, the capital was established at Columbus in 1816.

Since congress did not pass any formal act of admission there has been some controversy as to when Ohio became a state. The Enabling act was passed April 30, 1802, the first state legislature met March 1, 1803, the territorial judges gave up their offices on April 15, 1803, and the federal senators and representatives took their seats in congress Oct. 17, 1803. Congress decided in 1806, in connection with the payment of salaries to territorial officials, that March 1, 1803, was the date when state government began. During the War of 1812 the Indians under the lead of Tecumseh were again on the side of the British. Battles were fought at Fort Meigs (1813) and Fort Stephenson (Fremont, 1813), and Commodore Oliver Hazard Perry's naval victory on Lake Erie in 1813 was on the Ohio side of the boundary line.

Owing to the prohibition of slavery, the vast majority of the early immigrants to Ohio came from the north, but, until the Mexican War forced the slavery question into the foreground, the Democrats usually controlled the state, because the principles of that party were more in harmony with frontier ideas of equality. The Whigs were successful in the presidential elections of 1836 and 1840, partly because of the financial panic and partly because their candidate, William Henry Harrison, was a "favourite son," and in the election of 1844 because of the unpopularity of the Texas issue. Victory was with the Democrats in 1848 and 1852, but from the organization of the Republican party in 1854 until 1932 the state gave to the Republican presidential candidates its electoral votes, except in 1912 and 1916 when a split in the dominant party (Republican) allowed the Democrats to win. In the Civil War Ohio loyally supported the union, furnishing 319,659 men for the army. Dissatisfaction with the president's emancipation program resulted in the election of a Democratic congressional delegation in 1862, but the tide turned again after Gettysburg and Vicksburg; Clement L Vallandigham, the Democratic leader, was deported from the state by military order, and the Republicans were successful in the elections of 1863 and 1864. A detachment of the Confederate cavalry under Gen. John Morgan invaded the state in 1863, but was badly defeated in the battle of Buffington's Island (July 18).

Distinctive advance was made in adapting the constitution and the system of administration to the new needs of the state. At the election in 1910, a general constitutional convention was approved by a large majority. Delegates were chosen in Nov. 1911, and the convention sat from January to June 1912. The delegates, of whom the majority were Democrats, represented the progressive elements of both major parties. Forty-two amendments were submitted to the voters on Sept. 3, 1912, of which 34 were ratified; among those defeated were the abolition of capital punishment, woman suffrage and a $50,000,000 bond issue for a state system of roads. The tax reformers secured for the general assembly the power to impose inheritance, income and franchise taxes as well as taxes upon the production of coal, oil, gas and other minerals. Several of these sources of taxation were later adopted. In 1929 an amendment to the constitution was adopted authorizing classification of property for taxation. Under this amendment the classified tax was enacted in 1931, providing low rates for intangible personal property. In 1934 another amendment was adopted, fixing a limitation of 1% on real property except by vote of the people. Other laws fixed debt limitations which cannot be increased except by vote of the people. The League for Direct Legislation secured the initiative and referendum. Civil service was adopted in Ohio in 1912. In 1933 a retirement system was created for state employees. This was expanded in 1937 to include county, city and other local employees.

After 1930 political power in Ohio tended to fluctuate between the two major parties. In 1944 the voters elected a Democratic governor and a Republican majority in the general assembly; in 1946 a Republican governor and a Republican majority; in 1948 a Democratic governor and a Democratic majority; in 1950 a Democratic governor and a Republican majority.

Southern Ohio has suffered at various times from floods. During the great flood of 1884, the Ohio river at Cincinnati reached the highest flood stage ever recorded at that place (more than 71 ft. above normal), and throughout the Ohio valley millions of dollars worth of damage was done. Another disastrous flood in 1913, affecting especially the inhabitants of the Miami, the Scioto and the Muskingum river valleys, led to a measure for the protection of the river valley from future damage of the kind. This was made possible by the adoption of a constitutional amendment on conservation in 1912, which authorized, among other things, "laws providing for the formation of drainage and conservation districts." A third great flood occurred in 1937. The protective system, consisting of a series of dry reservoir dams, was undertaken by two conservancy districts—the Miami and the Upper Scioto—at a cost of $34,700,000 and $306,300 respectively. Later the Mahoning valley sanitary district was completed at a cost of about $17,000,000, and the Muskingum watershed conservancy district at an estimated cost of $34,000,000.

Population.—The population of Ohio in 1800 was 45,365; in 1830 it was 937,903; in 1870, 2,665,260; in 1910, 4,767,121; in 1940, 6,907,612; and in 1950, 7,946,627. This last figure represented an increase of 15.0% over the population in 1940. The population per square mile in 1950 was 193.8, as compared with 168.0 in 1940 and with 50.7 for the U.S. in 1950.

Of the 1950 population, 5,273,206, or 66.4%, lived in incorporated places of 2,500 or more, as compared with 66.8% in 1940, when these places constituted the urban area. The entire urban

URBAN AND RURAL POPULATION OF OHIO: 1870 TO 1950

The crosshatched part of the 1950 bar represents the population of the additional areas counted as urban under the new 1950 definition

population, under a new definition set up for 1950, which included also the thickly settled suburban area, or "urban fringe," adjacent to the 12 cities which had a population of 50,000 or more in 1940 and 5 unincorporated places of 2,500 or more outside this fringe, amounted to 5,578,274, or 70.2% of the state total.

The number of households in 1950 was 2,314,557, as compared with 1,897,796 in 1940. The average population per household had declined from 3.6 in 1940 to 3.4 in 1950.

The population of the state was distributed by colour and nativity in 1950 as follows: 87.9% native white; 5.6% foreign-born white; and 6.5% nonwhite, practically all Negro. There

were 97.8 males per 100 females in the 1950 population, as compared with 100.4 in 1940; 8.9% of the population was 65 years old or over; and 53.5% of the population 14 years old and over was in the labour force.

*Final figures for 1950 based on new definition. *See* comment in text.

Of the total number of employed males, 8.8% was engaged in agriculture, 6.9% in construction, 40.2% in manufacturing, 9.3% in transportation, communication and other public utilities, 15.7% in wholesale and retail trade and 14.3% in service activities of all kinds, including public administration.

Government.—Ohio is governed under the constitution of 1851 as revised by a constitutional convention in 1912 and subsequently amended. An amendment may be proposed at any time by either branch of the general assembly, and if after being approved by three-fifths of the members of both branches it is also approved at a general election by a majority of those voting on the question, it is declared adopted. Under the constitutions of 1802 and 1851 the suffrage was limited to "white male" citizens of the United States, but by an amendment approved in 1923 these words were stricken out and the constitution was made to conform with the 15th and 19th amendments to the federal constitution. The right of suffrage is bestowed on every United States citizen 21 years of age or over (with certain restrictions), provided he or she has resided within the state one year, in the county 30 days and in the voting precinct 28 days previous to the election. A system of permanent registration was established in 1929. Under this law registration is mandatory in all cities of 16,000 or more population. Any municipality of less than 16,000 may by ordinance become a registration municipality. Voters once registered are not required to register again except in case of removal, change of name, etc.

Registration may be required in territory adjacent to a registration city when deemed necessary to prevent fraud in elections. The constitution requires that all elections be by ballot. Constitutional amendments approved in 1912 provide for the use of the initiative and referendum in legislation.

The executive department consists of a governor, lieutenant governor, secretary of state, auditor, treasurer and attorney general. All are elected in November of even-numbered years for a term of two years; an exception is the auditor, who serves for four years. The right of veto was not given the governor until the adoption of a constitutional amendment in 1903. Bills must be vetoed in their entirety, except that in appropriation bills specific, individual items may be vetoed; a three-fifths vote of all the members of each house is required for repassage. The governor has full power to grant pardons and reprieves except for treason or conviction after impeachment by the general assembly. If he should die in office, resign or be impeached and removed from office, the officers standing next in succession are the lieutenant governor, the president of the senate and the speaker of the house of representatives in the order named. By an administrative reorganization act, passed in 1921, 37 departments, commissions, etc., were combined into 8 departments—finance, commerce, highways and public works, agriculture, health, industrial relations, education and public welfare—in which the former departments are known as divisions. Each department has at the head a director who is appointed by the governor and serves during his pleasure; each departmental director receives an annual salary of $8,600. In 1927 the division of public works was separated from the department of highways and made the ninth department with a director at its head. The system of administration thus established is closely analogous to that of the federal government.

The general assembly consists of a senate and a house of representatives, the members of which are elected for terms of two years. The ratio of representation in the senate is obtained by dividing the total population of the state by 35, the ratio in the house by dividing the population by 100. In 1950 there were 33 members of the senate and 135 members of the house. The constitution provided for a reapportionment every ten years, beginning 1861. Biennial sessions are held beginning the first Monday in January of odd-numbered years. The constitution prohibits special acts conferring corporate powers, retroactive legislation, legislation impairing obligation of contracts and legislation levying a tax on state, municipal and public-school bonds outstanding Jan. 1, 1913, and it limits the amount and specifies the character of public debts which the legislature may contract.

The judicial department is composed of a supreme court of seven judges, nine judicial courts of appeals of three judges each, courts of common pleas and probate, juvenile, justice of the peace and municipal courts. Under the constitution of 1802 judges were chosen by the legislature, but since 1851 they have been elected by direct popular vote, the judges of the supreme court being chosen at large. They are removable by a concurrent resolution approved by a two-thirds majority in each house of the general assembly, by impeachment and by special law.

The terms of supreme court judges, judges of the courts of appeals and of the courts of common pleas are six years; probate judges and justices of the peace, four years.

The principal units of local government are the county, the township, the city and the village. The chief county authority is the board of commissioners of three members elected for terms of four years. The other officials are the auditor and engineer, sheriff, treasurer, recorder, coroner, clerk of courts and prosecuting attorney, elected for four years. The county also has a board of education elected by the qualified voters of the county school district. This board appoints the county superintendent of schools, who has supervisory jurisdiction within the district. The county school district includes all rural and village districts within the county but excludes city and exempted village districts. The chief township authority is a board of trustees of three members, elected by popular vote for four years. The other township officials are the clerk, justices of the peace and constables. Under the constitution of 1802, municipal corporations were established by special legislation.

The constitution of 1851, however, provided for a general law, and the legislature in 1852 enacted a "general municipal corporation act," the first of its kind in the United States. The system was changed again in 1912 when the so-called "home-rule" amendment was put into the constitution. This allowed each municipality to make its own charter or constitution. As a result, a variety of charters exist. Municipalities with more than 5,000 population are cities; all others are villages.

State and county officials as well as U.S. senators and representatives are nominated at primaries held in even-numbered years.

Finances.—The Ohio constitution limited the bonded indebtedness of the state to $750,000. On Jan. 1, 1950, the state had no bonded debt under this limitation. In 1947, however, voters amended the constitution to permit the payment of about $300,000,000 in bonuses to veterans of World War II. Of this special issue of bonds there were outstanding on Jan. 1, 1949, $194,250,000. Chief sources of the general revenue fund were a 3% retail sales tax, cigarette excise, beer, wine and liquor taxes, a premium tax on insurance companies, corporation franchise tax, intangibles tax and inheritance tax. Thus the ordinary expenses of the state government were met almost entirely by indirect taxation. In

1950 $74,000,000 was spent for improvement of highways. In the fiscal year 1950 the state received $7,136,000 more in income than it had anticipated, much of it from the sales tax as volume of sales swelled. The state spent nearly $52,000,000 out of surplus for new buildings and other capital improvements and ended the 1950 fiscal year with a net cash balance of $68,769,035. The state budget for the 1949–51 biennium was $629,180,804. The valuation assigned to property in the state tax duplicate was $13,953,000,000 in 1950. At the close of 1949 there were 423 state and private banks in Ohio having combined resources of $4,282,576,357 and total deposits of $3,961,880,203. National banks in the state numbered 241 with combined resources of $3,482,064,000 and total deposits of $3,235,255,000. There were 486 state-chartered savings and loan associations with combined resources of $1,237,924,904 and 131 federal savings and loan associations with total assets of $680,569,750.

Education.—Ohio has an excellent system of public education extending from the kindergarten through college and university work. The basis of Ohio's educational system was laid by an act of congress in 1785 setting apart 1 sq.mi. in each township of 36 sq.mi. for the support of education. After the reorganization of the administrative departments in 1921, the superintendent of public instruction became the chief administrative officer of the department of education with the title director of education. The tax limitation amendment curtailed the revenues of the public schools and in 1935 the school foundation was established. Under this system the state gives to the local school districts each year, subject to definite restrictions, sufficient funds to bring the schools of the state up to certain standard specifications. The cost to the state is about $50,000,000 per annum.

Operating expenditures of the public schools in Ohio for 1948–49, according to the annual report of the director of education, were $210,654,043. Enrolment in public schools that year was 1,185,900 and the teaching staff numbered 42,356. Enrolment in parochial schools of the state was 181,924 and in private schools 4,017.

The institutions of higher education supported in whole or in part by the state are: Ohio university at Athens, founded in 1804 on the proceeds derived from two townships granted by congress to the Ohio company; Miami university (chartered in 1809) at Oxford, which received the proceeds from a township granted by congress in the Symmes purchase; Ohio State university (1873) at Columbus, which received the proceeds from the lands granted by congress under the act of 1862 for the establishment of agricultural and mechanical colleges, and reorganized as a university in 1878. Bowling Green State university and Kent State university were normal schools prior to 1935. Ohio Central college, at Wilberforce, formerly was a part of Wilberforce university. Akron, Cincinnati and Toledo support universities. Among the numerous denominational or privately endowed colleges and universities within the state are Western Reserve university and Case Institute of Technology at Cleveland, Oberlin college at Oberlin and Ohio Wesleyan university at Delaware.

Charities and Correction.—The director of public welfare has under his general control administration of poor relief; aid to the aged, the blind and dependent children; state hospitals for the insane, epileptics and tubercular patients; institutions for the feeble-minded; a soldiers' and sailors' home; industrial schools for boys and girls; reformatories for men and women; a prison farm and penal honour camps; and Ohio penitentiary. The total operating costs for all institutions under the supervision of the department of public welfare in 1949 were $26,372,000. For the first half of 1950 the average case load for poor relief was 116,356. Expenditure for aid for the aged in the first six months of 1950 was $35,643,439. On July 1, 1950, Ohio had 37,697 mental patients and 14,798 persons in penal or juvenile institutions or on parole.

Agriculture.—Ohio is important agriculturally as well as industrially. Usually it ranks among the first ten states in the total value of its agricultural products. The principal crops are corn, wheat, soybeans, oats, hay, potatoes, tobacco, apples, peaches, grapes, barley, rye, buckwheat, popcorn and sugar beets. The total harvested acreage of principal crops in 1949 was 10,850,000. Acreage devoted to the principal crops that year was as follows: corn, 3,617,000; wheat, 2,353,000; soybeans, 858,000; hay, 2,429,000; oats, 1,334,000; potatoes, 38,000; sugar beets, 24,000; tobacco, 20,900; barley, 16,000; rye, 15,000; buckwheat, 11,000; and popcorn 9,500.

Production of the leading crops in 1949 was as shown in Table II.

TABLE II.—*Agricultural Production in Ohio*

Crop	1949	Average, 1938–47
Corn, bu.	202,552,000	160,389,000
Wheat, bu.	60,002,000	43,274,000
Hay, tons	3,556,000	3,714,000
Soybeans, bu.	20,592,000	16,276,000
Oats, bu.	48,024,000	40,495,000
Potatoes, bu.	6,270,000	8,600,000
Sugar beets, tons	247,000	290,000
Tobacco, lb.	29,220,000	24,165,000
Barley, bu	464,000	774,000
Rye, bu.	270,000	869,000
Buckwheat, bu.	248,000	300,000
Popcorn, lb.	20,425,000	19,929,000
Apples, bu.	5,446,000	3,875,000
Peaches, bu.	1,194,000	843,000
Pears, bu.	272,000	322,000
Grapes, tons	15,800	15,650
Cherries, tons	2,280	3,193
Maple syrup, gal.	150,000	208,000

The agricultural trend in Ohio in the 1940–50 decade was toward smaller farms and more intensive cultivation with mechanical equipment and fertilization resulting in higher yields per acre. Average number of farm units (1930–49) was 220,000 having a total estimated value of $2,500,000,000.

Livestock and poultry products are of great importance. Normally the Ohio farmers receive more than twice as much cash income from livestock and products as they do directly from their crops.

Mineral Products.—The mineral wealth of Ohio is well distributed in both area and products. In 1950 pig iron, bituminous coal, coke, clay and natural gas were the chief products, but the state also had considerable production in cement, ferro-alloys, lime, petroleum, salt, sand and gravel and stone. The total production for 1948, exclusive of pig iron, ferroalloys and coke, was valued at $328,228,000, as compared with $291,960,000 in 1947, according to the U.S. bureau of mines.

The fire-clay mines of Tuscarawas, Jefferson, Columbiana, Stark and Carroll counties supply the raw material for the greater part of the state's pottery, tile and brick industry. The coal fields, comprising a total area of 10,000 sq.mi. or more, are in the eastern half of the state. In 1948, 36,104,000 short tons were mined, as compared with 37,548,204 in 1947 and 32,314,262 in 1946. Natural gas is found in the eastern, central and northwestern parts of the state; production in 1948 was 65,619,000,000 cu.ft. as compared with 68,946,000,000 cu.ft. in 1947 and 61,570,000,000 cu.ft. in 1946. This gas production was valued at $12,901,000 in 1948, $13,548,000 in 1947 and $11,280,000 in 1946.

The output of pig iron, Ohio's leading mineral in 1948, was 12,367,227 short tons valued at $469,653,906. Production of coke was 10,562,486 short tons valued at $128,843,686. Other important mineral products of the state in 1948 included: 10,020,198 bbl. of cement valued at $20,496,930; 259,271 short tons of ferro-alloys valued at $21,852,890; 1,936,211 short tons of lime valued at $21,473,000; 3,300,000 bbl. of petroleum valued at $13,733,000; 2,752,696 short tons of salt valued at $5,884,343; and 15,508,815 short tons of sand and gravel valued at $15,149,848.

Some of the best sandstone in the United States is obtained from Cuyahoga and Lorain counties. It is exceptionally pure in texture and durable. From the sandstone known as Berea grit, a large portion of the nation's grindstones and whetstones is obtained. Total output of Ohio quarries in 1948 was 20,274,570 short tons valued at $27,552,017. Total value of raw clay and clay products was $69,175,821.

Manufactures.—Ohio is pre-eminently a manufacturing state. The number of its manufacturing establishments rose from 9,543 in 1939 to 12,303 in 1947. Value added by manufacture was tripled in this period, from $2,116,434,000 in 1939 to $6,359,006,000 in 1947. Salaries and wages paid by the 12,303 manufacturing plants in 1947 to their 1,194,603 employees totalled $3,560,075,000. The

average number of employees covered by unemployment compensation in 1949 was 2,078,261.

The most important manufacturing industries are those working with iron and steel. The glow of the blast furnaces lights the skies of northern Ohio and at some spots along the Ohio river. Final products range from tiny shoelace tips to giant machines as high as a five-story building. In the 1947 United States census of manufactures these products accounted in a large measure for the five highest classifications in the value added by manufacture in the state. These classifications together with the value added by manufacture were: machinery (except electrical) $1,251,011,000; primary metal industries $852,772,000; fabricated metal products $634,746,000; transportation equipment $483,421,000; and electrical machinery $471,593,000.

Other leading manufactures in 1947 with the value added by manufacture were: food and kindred products $413,216,000; rubber products $381,215,000; chemicals, paints and allied products $347,226,000; printing and publishing industries $322,283,000; stone, clay and glass products $293,881,000; paper and allied products $199,107,000; furniture and fixtures $128,293,000; apparel and related products $127,753,000; petroleum and coal products $95,811,000; leather and leather products $68,293,000; textile mill products $58,183,000; instruments and related products $41,381,000; lumber and products, except furniture, $37,521,000; tobacco manufactures $14,504,000.

The great manufacturing centres are Cleveland, Akron, Cincinnati, Toledo, Youngstown, Dayton, Columbus, Canton and Springfield. A large portion of the iron and steel is manufactured in Cleveland, Youngstown, Steubenville, Lorain, Bellaire, Canton, East Youngstown and Ironton. Most of the transportation equipment is manufactured in Cleveland; most of the cash registers and calculating machines in Dayton; most of the motor tires and other rubber goods in Akron. Beginning in the middle of the 20th century there was a notable expansion in the chemical industries in the Cleveland-Ashtabula area along Lake Erie and also along the Ohio river.

Transportation and Commerce.—The most important natural means of transportation are the Ohio river on the southern border and Lake Erie on the northern border. One of the first great public improvements made within the state was the connection of these waterways by two canals—the Ohio and Erie canal from Cleveland to Portsmouth and the Miami and Erie canal from Toledo to Cincinnati. The Ohio and Erie was opened throughout its entire length (309 mi.) in 1832. The Miami and Erie was completed from Middletown to Cincinnati in 1827; in 1845 it was opened to the lake (250 mi. from Cincinnati). A flood in 1913 wrecked these canals.

The national government began in 1825 to extend the National road across Ohio from Bridgeport, opposite Wheeling, W.Va., through Zanesville and Columbus, and completed it to Springfield in 1837. Before the completion of the Miami and Erie canal to Toledo, the building of railways was begun in this region, and in 1836 a railway was completed from that city to Adrian, Mich. At the close of 1949 there was a total mileage of 8,400 as compared with 9,159 in 1915, this reduction being a part of a general shrinkage prevalent throughout the country during this period. As the building of steam railways lessened and then ceased, the building of suburban and interurban electric railways was begun. These railways were rapidly extended until a maximum of 4,236 mi. was reached in 1917, and all the more populous districts were connected by them; but by 1950 these lines had almost vanished as a result of the widespread growth in motor traffic.

In 1949 there were 85,517 mi. of highway in the state outside municipalities. Of this, 16,065 mi. were classified as rural, 28,798 mi. as county and 40,654 mi. as township.

Iron ore, coal, limestone, grain and automobiles are the principal cargoes handled by Ohio's chief Lake Erie ports of Cleveland, Toledo, Ashtabula, Sandusky, Conneaut, Lorain and Fairport. Iron ore shipments to Ohio ports in 1949 totalled 37,547,717 tons.

Foreign ship commerce had grown, with 25 ships of foreign registry making 71 sailings in and out of Cleveland in 1949. These vessels reach the Great Lakes by way of the St. Lawrence river and the Welland canal. Cincinnati is the state's principal port on the Ohio river. Ohio had 3,500 mi. of certificated air line routes within its boundaries and 360 airports and landing fields in 1950.

OHIO COMPANY, a name of two companies organized in the 18th century for the colonization of the Ohio valley. The first Ohio company was organized in 1749, partly to aid in securing for the English control of the valley, then in dispute between England and France, and partly as a commercial project for trade with the Indians. The company was composed of Virginians, including Thomas Lee (d. 1750) and the two brothers of George Washington, Lawrence (who succeeded to the management upon the death of Lee) and Augustine; and of Englishmen, including John Hanbury, a wealthy London merchant. In 1752 the company had a pathway blazed between the small fortified posts at Will's creek (Cumberland), Md., and at Redstone creek (Brownsville), Pa., which it had established in 1750; but it was finally merged in the Walpole company (an organization in which Benjamin Franklin was interested), which in 1772 had received from the British government a grant of a large tract lying along the southern bank of the Ohio as far west as the mouth of the Scioto river. The Revolutionary War interrupted colonization and nothing was accomplished.

The second company, the Ohio Company of Associates, was formed at Boston in 1786. The leaders in the movement were General Rufus Putnam, Benjamin Tupper (1738–92), Samuel Holden Parsons (1737–89) and Manasseh Cutler. Cutler was selected to negotiate with congress, and seems to have helped to secure the incorporation in the ordinance for the government of the Northwest territory of the paragraphs which prohibited slavery and provided for public education and for the support of the ministry. On Oct. 27, 1787, Cutler and Major Winthrop Sargent (1753–1820), who had joined him in the negotiations,

signed two contracts; one was for the absolute purchase for the Ohio company, at 66⅔ cents an acre, of 1,500,000ac. of land lying along the north bank of the Ohio river, from a point near the site of the present Marietta, to a point nearly opposite the site of the present Huntington, W. Va.; the other was for an option to buy all the land between the Ohio and the Scioto rivers and the western boundary line of the Ohio company's tract, extending north of the tenth township from the Ohio, this tract being preempted by "Manasseh Cutler and Winthrop Sargent for themselves and others"—actually for the Scioto company (*see* GALLIPOLIS). On the same day Cutler and Sargent "for themselves and associates" transferred to William Duer, then secretary of the Treasury board, and his associates "one equal moiety of the Scioto tract of land mentioned in the second contract," it being provided that both parties were to be equally interested in the sale of the land, and were to share equally any profit or loss. Colonists were sent out by the Ohio company from New England, and Marietta, the first permanent settlement in the present state of Ohio, was founded in April, 1788.

Hulbert, ed., *The Records of the Original Proceedings of the Ohio Company* (Marietta, O., 1917); and Herbert T. Leyland, "The Ohio Company," *Hist. and Philos. Soc. of Ohio, Quart. Pub.*, vol. xvi., no. 1 (Cincinnati, 1921).

OHIO RIVER, the principal eastern tributary of the Mississippi river, U.S.A. It is formed by the confluence of the Allegheny and Monongahela rivers at Pittsburgh (Pa.), and flows north-west nearly to the west border of Pennsylvania, south-south-west between Ohio and West Virginia, west by north between Ohio and Kentucky, and west-south-west between Indiana and Illinois on the north and Kentucky on the south. It is the largest of all the tributaries of the Mississippi in respect to the amount of water discharged (an average of about 158,000cu.ft. per sec.), is first in importance as a highway of commerce, and in length (967m.), as well as in the area of its drainage basin (approximately 210,000sq.m.) it is exceeded only by the Missouri. The slope of the river at low water ranges from 1ft. or more per mile in the upper section to about 0·75ft. per mile in the middle section and 0·29ft. per mile in the lower section, and the total fall is approximately 500ft. The greatest falls are at Louisville, where the river within a distance of 2·25m. descends 23·9ft. over an irregular mass of limestone. The ordinary width of the upper

A SHIPMENT OF STEEL TUBES AWAITING TRANSPORTATION DOWN THE OHIO RIVER

half of the river is uniform, from 1,200 to 1,500ft. Islands are numerous and vary in size from an acre or less to 5,000ac.

Besides its parent streams, the Allegheny and the Monongahela, the Ohio has numerous large branches. On the north it receives the waters of the Muskingum, Scioto, Miami and Wabash rivers, and on the south those of the Kanawha, Big Sandy, Licking, Kentucky, Green, Cumberland and Tennessee.

The drainage basin of the Ohio, in which the annual rainfall averages about 43in., is especially in the southern part of the river, of the "quick-spilling" kind, and as the swift mountain streams in that section are filled, the Ohio rises very suddenly and not infrequently attains a height of 30 to 50ft. or more above low water level spreads out 10 to 15 times its usual width, submerges the bottom lands, and causes great damage. In March 1913, an especially destructive flood reached the highest stages on record on that part of the river between Wheeling and Cincinnati and on the tributaries entering from the north.

Robert Cavelier, Sieur de La Salle, asserted that he discovered the Ohio and descended it until his course was obstructed by a fall (thought to be the falls at Louisville); this was probably in 1670, but until the middle of the next century, when its strategic importance in the struggle of the French and the English for the possession of the interior of the continent became fully recognized, little was generally known of it. By the treaty of 1763 ending the Seven Years' War the English finally gained undisputed control of the territory along its banks. By the treaty of 1783 the entire Ohio country became a part of the United States and by the famous Ordinance of 1787 the north side was opened to settlement. Most of the settlers entered the region by the headwaters of the Ohio and carried much of their market produce down the Ohio and Mississippi to New Orleans.

DEVELOPMENT

Until the successful navigation of the river by steamboats a considerable portion of the imports was carried overland from Philadelphia or Baltimore to Pittsburgh. The first steamboat on the Ohio was the "New Orleans," which was built in 1811 by Nicholas J. Roosevelt and sailed from Pittsburgh to New Orleans in the same year, but it remained for Capt. Henry M. Shreve (1785–1854) to demonstrate with the "Washington," which he built in 1816, the success of this kind of navigation on the river. From 1820 to the Civil War the steamboat on the system of inland waterways of which the Ohio was a part was a dominant factor in the industrial life of the Middle West. Cincinnati. Louisville and Pittsburgh on its banks were extensively engaged in building these vessels. Until the Erie canal was opened in 1825 the Ohio river was the chief commercial highway between the East and the West.

The Federal Government in the year 1827 undertook to remove the snags and to increase the depth of water on the bars by the construction of contraction works, such as dikes and wing dams, and appropriations for these purposes as well as for dredging were continued until 1844 and resumed in 1866; but as the channel obtained was less than 3ft. in 1870, locks with movable dams—that is, dams that can be thrown down on the approach of a flood—were then advocated, and five years later Congress made an appropriation for constructing such a dam, the Davis island dam immediately below Pittsburgh, as an experiment. This was opened in 1885 and was a recognized success. As a result of the activity of the Ohio Valley Improvement Association, Congress authorized the secretary of war to appoint a board of engineers to report on the merits of a channel 9ft. in depth. The board reported in 1908 in favour of such a channel.

In 1910 Congress adopted the report, and provision was made for a comprehensive project for canalizing the Ohio. By mid-20th century a system of 46 locks and dams was open to navigation. The entire length of the river was at least nine feet deep most of the time.

In order to maintain the nine-foot depth in areas with unfixed bars or shoals, dredging operations were carried on under the supervision of the U.S. army corps of engineers.

A number of the tributaries of the Ohio river also had a depth of at least nine feet.

BIBLIOGRAPHY.—The Board of Engineers' *Report of Examination of Ohio River with a View to Obtaining Channel Depths of 6 and 9 Ft. Respectively* (Washington, 1908); A. B. Hulbert, *Waterways of Westward Expansion* (Cleveland, 1903), and *The Ohio River, a Course of Empire* (1906).

OHLAU, a town in the Prussian province of Silesia, Germany, 16 mi. by rail S.E. of Breslau, on the Oder. Pop. (1939) 12,710. It has a castle, became a town in 1291 and passed to Prussia in 1742. Ohlau is the centre of a tobacco-growing district.

ÖHLENSCHLÄGER, ADAM GOTTLOB (1779–1850), Danish poet, was born in Vesterbro, a suburb of Copenhagen, on

Nov. 14, 1779. His father, a Schleswiger by birth, was at that time organist, and later became keeper, of the royal palace of Frederiksberg. Through Edvard Storm, Adam received a nomination to the college called "Posterity's High School," of which Storm was the principal. Storm himself taught the class of Scandinavian mythology, and thus Öhlenschläger received his earliest bias towards the traditions of his ancestors. His studies were interrupted first by the death of his mother, and by the English attack on Copenhagen in April 1801, which, however, inspired a dramatic sketch (*April the Second 1801*).

In the summer of 1802, when Öhlenschläger had an old Scandinavian romance, as well as a volume of lyrics, in the press, the young Norse philosopher, Henrik Steffens, came back to Copenhagen after a long visit to Schelling in Germany, full of new romantic ideas. His lectures at the university, in which Goethe and Schiller were for the first time revealed to the Danish public, created a great sensation. Steffens and Öhlenschläger met, and after a conversation of sixteen hours the latter went home and wrote at a sitting his splendid poem *Guldhornene*, in a manner totally new to Danish literature. A volume of poems in the romantic style is now chiefly remembered as containing the lovely piece called *Sanct-Hansaften-Spil*. The next two years saw the production of the epic of *Thors Reise til Jotunheim*, the charming poem in hexameters called *Langelandsreisen*, and fantasy *Aladdin's Lampe* (1805).

At the age of twenty-six Öhlenschläger was universally recognized, even by the opponents of the romantic revival, as the leading poet of Denmark. He now collected his *Poetical Writings* in two volumes. He obtained a grant for foreign travel from the government, and joined Steffens at Halle in August 1805. Here he wrote the first of his great historical tragedies, *Hakon Jarl*. In the spring of 1806 he went on to Weimar, where he spent several months in daily intercourse with Goethe. The autumn of the same year he spent with Tieck in Dresden, and proceeded in December to Paris. Here he resided eighteen months, and wrote his three famous masterpieces, *Baldur hin Gode* (1808), *Palnatoke* (1809) and *Axel og Valborg* (1810). In the spring of 1809 Öhlenschläger went to Rome to visit Thorwaldsen, and in his house wrote (in German) his tragedy of *Correggio*.

He returned to Denmark in the spring of 1810 to take the chair of aesthetics at the University of Copenhagen. In 1811 he published the Oriental tale of *Ali og Gulhyndi*, and in 1812 the last of his great tragedies, *Staerkodder*. His talent culminated in the cycle of verse-romances called *Helge*, published in 1814. The tragedy of *Hagbarth og Signe*, 1815, showed a distinct falling-off in style. In 1817 he went back to Paris, and published *Hroars Saga* and the tragedy of *Fostbrödrene*. In 1818 he was again in Copenhagen, and wrote the idyll of *Den lille Hyrdedreng* and the Eddaic cycle called *Nordens Guder*. His next productions were the tragedies of *Erik og Abel* (1820) and *Vaeringerne i Miklagaard* (1826), and the epic of *Hrolf Krake* (1829).

In 1829 Öhlenschläger was publicly crowned with laurel in front of the high altar in Lund cathedral by Bishop Esaias Tegnér, as the "Scandinavian King of Song." His last volumes were *Tordenskjold* (1833), *Dronning Margrethe* (1833), *Sokrates* (1835), *Olaf den Hellige* (1836), *Knud den Store* (1838), *Dina* (1842), *Erik Glipping* (1843) and *Kiartan og Gudrun* (1847). On his seventieth birthday, Nov. 14, 1849, a public festival was arranged in his honour, and he was decorated by the king of Denmark. He died on Jan. 20, 1850, and was buried in the cemetery of Frederiksberg. Immediately after his death his *Erindringer* ("Recollections") were published in two volumes.

With the exception of Holberg, there has been no Danish writer who has exercised so wide an influence as Öhlenschläger. He awakened in his countrymen an enthusiasm for the poetry and religion of their ancestors, and his name remains to this day synonymous with Scandinavian romance. His plays, partly, no doubt, in consequence of his own early familiarity with acting, fulfilled the stage requirements of the day, and were popular beyond all expectation. The earliest are the best—Öhlenschläger's dramatic masterpiece being, without doubt his first tragedy, *Hakon Jarl*. In his poems and plays alike his style is limpid, elevated, profuse; his flight is sustained at a high pitch without visible excitement. His fluent tenderness and romantic zest have been the secrets of his extreme popularity. Although his inspiration came from Germany, he is not much like a German poet, except when he is consciously following Goethe; his analogy is rather to be found among the English poets, his contemporaries. With all his faults he was a great writer, and one of the principal pioneers of the romantic movement in Europe. (E. G.; X.)

The critical edition of Öhlenschläger's works is that by J. L. Lubenberg (32 vols., 1857–62). *See* B. Andersen, *Öhlenschläger et livs poesie* (3 vols., 1899).

OHLIGS, former German town known before 1891 as Merscheid, 17 mi. by rail N. of Cologne, on the railway to Elberfeld. Pop. was 29,812. It manufactured cutlery, surgical instruments and hardware and united with Solingen in 1929.

OHM, GEORG SIMON (1787–1854), German physicist, was born at Erlangen on March 16, 1787, and was educated at the university there. He became professor of mathematics in the Jesuits' college at Cologne in 1817, and in the polytechnic school of Nuremberg in 1833. In 1849 he was appointed conservator of the physical collection at Munich, and in 1852 professor of experimental physics in the high school of Munich, where he died of apoplexy on July 7, 1854. His writings were numerous, but, with one important exception, not of the first order. The exception is his pamphlet, published in Berlin in 1827, with the title *Die galvanische Kette mathematisch bearbeitet*. This work, the germs of which had appeared during the two preceding years in the journals of Schweigger and Poggendorff, has exerted a great influence on the whole development of the theory and applications of current electricity. (*See* ELECTRICITY.) The most important part of the pamphlet is summarized in what is now known as Ohm's Law. (*See* RESISTANCE, MEASUREMENT OF.) This work was so coldly received that Ohm's susceptibilities were hurt, and he resigned his post at Cologne. He eked out a precarious livelihood until appointed at Nuremberg. At this time his work began to be recognized, he was awarded the Copley medal of the Royal Society in 1841 and was made a foreign member of that society in 1842. In addition to a number of papers on mathematical subjects, Ohm wrote a memoir on interference in uniaxial crystals, and also a *Text Book of Physics* (1854).

OHMMETER, an electrical instrument employed for measuring insulation-resistance or other high electrical resistances. The ohmmeter is described in INSTRUMENTS, ELECTRICAL: *Resistance Measuring Instruments*.

OHNET, GEORGES (1848–1918), French novelist and man of letters, was born in Paris on April 3, 1848. After the war of 1870 he became editor of the *Pays* and the *Constitutionnel* in succession. In collaboration with the engineer and dramatist Louis Denayrouze (b. 1848) he produced the play *Regina Sarpi*, and in 1877 *Marthe*. He was an admirer of George Sand and bitterly opposed to the realistic modern novel. He began a series of novels, *Les batailles de la vie*. The series included *Serge Panine* (1881) which was crowned by the Academy; *Le Maître de forges* (1882), *La Grande Marnière* (1885), *Volonté* (1888), *Dernier amour* (1891). Many of his novels have been dramatized with great success, *Le Maître de forges*, produced at the Gymnase in 1883, holding the stage for a year. He published in 1908 *La route rouge*, and in 1912 *La serre de l'aigle*. His last work was *Journal d'un bourgeois de Paris pendant la guerre de 1914* (1914–18).

OIL, MINERAL: *see* PETROLEUM.

OIL, PALM: *see* PALM OIL.

OIL, SHALE: *see* SHALE OIL.

OIL-BIRD or **GUACHARO** (*Steatornis caripensis*), the sole member of a family, *Steatornithidae*. As big as a crow, its plumage exhibits blended tints of chocolate-colour and grey, barred and pencilled with dark-brown or black, and spotted in places with white. The guacharo is nocturnal, slumbering by day in deep and dark caverns. Towards evening it arouses itself and, with croaking and clattering, which has been likened to that of casta-

nets, it approaches the exit of its retreat. In Trinidad the young are esteemed a great delicacy for the table.

OIL BUNKERING: *see* BUNKERING OF SHIPS.

OIL CAKE, a feeding stuff of great value, prepared from the residue resulting from the crushing of various oilseeds. For details *see* FEEDING STUFFS AND LIVESTOCK FEEDING; COTTONSEED; LINSEED; COCO-NUT OIL AND CAKE.

OIL CITY, a city of Venango county, Pennsylvania, U.S.A., on the Allegheny river, at the mouth of Oil creek, 75 mi. N. of Pittsburgh. It is served by the Erie, the New York Central and the Pennsylvania railways and has a municipal airport. The population in 1950 was 19,581; in 1940 it was 20,379, with as many more in near-by places.

The city lies 1,000 ft. above sea level, in a rolling and wooded country.

The central part is almost encircled by a deep bend of the river, and is connected with the south, west and east sides by several bridges.

Oil City is the metropolis and market of the Pennsylvania oil region; has large oil refineries and machine shops; and manufactures steel drums, steel tubing, tin cans, bottles, gas engines, pumping machinery and other oil well supplies and various other commodities. Natural gas is used for domestic and industrial purposes.

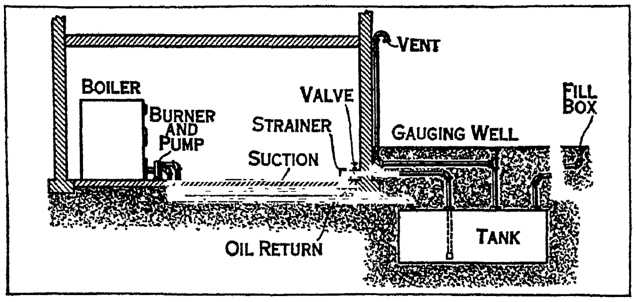
The city has a commission form of government.

Oil City was founded in 1860, following the drilling of the Drake well at Titusville (16 mi. N.) on Aug. 27, 1859. It was incorporated as a borough in 1863 and as a city in 1871. Between 1860 and 1870 there were 20 passenger boats and towboats and 3,000 flatboats plying the river, and 17,000,000 bbl. of oil were shipped to Pittsburgh. Trading in oil certificates led to the establishment of the Oil exchange, which for many years set the price of oil for the world.

OIL ENGINE: *see* INTERNAL COMBUSTION ENGINES.

OIL FUEL: see FUEL: A GENERAL SURVEY.

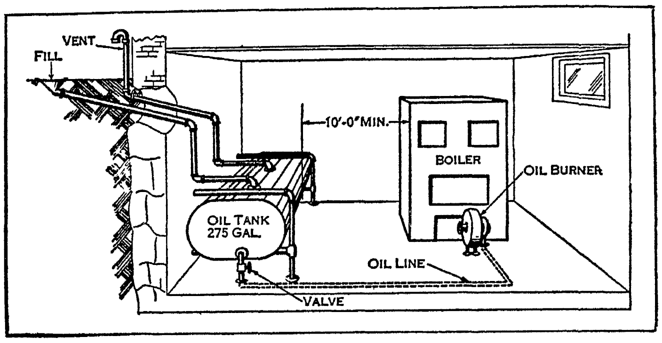
OIL HEATING, DOMESTIC, that branch of the heating of dwellings and other buildings in which the fuel burned is a mineral oil, such as shale oil or one of the heavier and less expensive grades of petroleum (*q.v., see* also KEROSENE). Oil has been used for fuel and for heating since the time of Moses; but the mechanical development of the oil burner dates from the middle



BY COURTESY OF THE DOMESTIC OIL HEATING INSTITUTE
CHARACTERISTIC UNDERGROUND TANK INSTALLED BELOW BURNER LEVEL

of the 19th century, and only after 1922, in the United States particularly, did it come into widespread use. "Oil heating" refers here only to the method of generating heat, without regard to the medium (steam, hot water or air) used to carry the heat throughout the building; "oil" refers here only to petroleum. Oil in its native state will burn, but not with maximum effect until it is atomized and mixed with air. The history of modern oil heating is the record of the search for simple and efficient methods of preparing heavy oils for complete combustion. In 1861 a mechanic named Werner, employed in one of the refineries of the Russian oil fields of the Caucasus, first suggested that what was then "refuse oil" be used as fuel; his burner, consisting of a series of griddles over which the oil trickled and burned was widely used though not patented until 1867. In 1862 two experimenters took out patents on an oil burner which solved the combustion problem by introducing the oil into the furnace in a gaseous state, the heavy oil first being heated and made to give off lighter oils. In 1863 Brydges Adams introduced into America the first spray burner, and in 1866 Ayden brought out a burner using hot air to atomize the oil and Spakorsky one using super-heated steam. Spakorsky's method was later embodied in an oil burner by Thomas Urquhart, an American at that time in the employ of a Russian railway.

Public interest was attracted by the possibilities of oil burning with a very considerable increase in the oil production of California and Texas about 1900. Small burners, suitable for heating forges, treating furnaces, drying ovens and melting furnaces were soon produced. Larger burners were designed for boilers producing steam for power and heat. In 1902 and 1903 the U.S. naval liquid fuel board conducted tests of all available burners to determine whether vessels of the U.S. navy should be equipped for oil burning. The report, completed in 1904, was so favourable that the newer vessels were immediately designed to burn oil fuel and many of the older ones were converted.



CHARACTERISTIC 275GAL. TANK INSTALLED IN BASEMENT

The first attempts at domestic oil burning were crude and, in the majority of cases, consisted primarily of a pipe from a tank dropping the oil on hot, refractory material in an open pan. These were followed by natural-draught vaporizing burners, which, however, did not provide the uniform combustion necessary for economical and reliable operation. A later development was the mechanical-draught automatic burner, the foundation of the modern, domestic oil heating industry. In 1919, following World War I, oil fuel began to enter the American home on a national scale.

The rapid rise of the oil burner was a result of its convenience; an oil fire can be built or banked by the turn of a switch. Through electrical control, all the processes of furnace tending were made automatic.

Another advantage is that oil may be conveniently stored in congested business districts. The labour required for attending oil-fired boilers is considerably less than that where coal is used, even when this is handled by modern equipment.

Types of Burners.—There are numerous varieties of oil burners, but all may be included under two distinct types: the natural draught and the mechanical draught burners. In the first type, sometimes called a gravity burner, there are no moving parts and the force of the draught depends on the size and height of the chimney, and on the differences in temperature and density between the outside air and the flue gases in the chimney. For this reason it is affected by changes in the weather, wind currents above the chimney and similar factors controlling variations in draught intensity. The natural draught burner is usually limited to heating on a small scale and requires lighter oils for efficient operation. In the second type, the air for combustion is supplied by a fan or blower. When a fan is used, the entire amount of air for combustion is usually supplied under pressure. The mechanical draught burner, since its air supply is controlled for the most part by the fan or blower, is more efficient than the natural draught burner, and maintains uniformly efficient combustion under all conditions.

Burners are also classified by the means employed to prepare the fuel for combustion. The oil may be atomized or vaporized. In the latter type, oil is prepared for combustion by first being heated. The vapour is mixed with the air just before or during

the combustion process. Burners of this type are especially flexible, with low oil capacities, and moving mechanical parts can be eliminated. In the atomizing burner, high or low pressure air or steam, mechanical pressure or rotating parts break up the fuel into small particles which are quickly vaporized by the heat of combustion. In commercial installations, where oil fuel is used in the heating of factories, office buildings, schools, theatres, apartments, etc., atomizing burners are used almost to the exclusion of other types because of their ability to burn the heavier and cheaper grades of fuel oils. The modern oil burner is automatic. A room thermostat electrically controls the burner so that the heat of the house can be kept constant within two degrees on either side of the desired temperature. A boiler or furnace control prevents overheating of the boiler and, in the case of a steam boiler, prevents abnormal pressures being developed. A burner safety control establishes a time limit within which the oil must be ignited every time the burner is started up; if the oil is not ignited the burner mechanism is shut down. When ignition is electric, it is accomplished by means of a spark from a high-tension transformer or by a hot resistance coil. The spark type of ignition is more widely used. Some burners require a gas pilot. An oil burner can be installed in practically any hot water or steam boiler, or in any warm-air heater.

The fuel oil used in automatic oil heating equipment varies in accordance with the needs of the individual burner; ranging from very light, untreated kerosene or distillate for burners that prepare the fuel for combustion by vapourization to heavier, straw-coloured distillates and dark coloured gas or Diesel oils for burners that employ atomization in preparing the fuel for combustion. The Commercial Standards Specifications for fuel oils as published by the U.S. Bureau of Standards are the most widely recognized specifications covering fuel oils. The grade numbers and names, together with their old designations and approximate A.P.I. (American Petroleum Institute) gravity range are:

Specification Number	Standard Name	Approximate Gravity Range	Old Designation Name
1	No. 1 Fuel Oil	40–36	Distillate
2	No. 2 Fuel Oil	36–30	Gas Oil
3	No. 3 Fuel Oil	30–22	Light Fuel Oil
5	No. 5 Fuel Oil	24–18	Medium Fuel Oil
6	No. 6 Fuel Oil	18–10	Heavy Fuel Oil

Oils number 1, 2, 3 are most generally used in automatic burners. Oils 5 and 6, because they generally require pre-heating, are used primarily in large commercial and industrial installations.

The utility of a fuel oil for domestic heating depends also upon its flash point. The flash point of any oil is the lowest temperature at which the vapours on the surface of the oil will ignite and burn momentarily on application of a spark or flame. About 20° F. above the flash point is the fire point of the oil. This is the temperature at which the oil will ignite and burn continuously.

It is desirable that this fire point should be sufficiently low so that the oil will ignite from a cold start without hesitation. A flash point as low as 100° F. or 110° F. is allowable, and an oil with a flash point above 230° F. should not be used with most burners because of the difficulty of initiating ignition.

(H. F. T.)

OILLETS, the architectural term for the arrow slits in the walls of mediaeval fortifications, but more strictly applied to the round hole or circle with which the openings terminate; also applied to the small circles in the tracery head of the windows of the Decorated and Perpendicular periods which were sometimes varied with trefoils and quatrefoils.

OIL PAINTING, TECHNIQUE OF. As the musician must be taught, and the subtlest of harmonies are subject to material limitations, so the art of the painter must be learned, and he, more perhaps than any other artist, is bound by severe material necessities. It is not intended here to give instruction in the art of painting or to express individual preferences. The object in view is rather, taking as a basis the various methods employed by the great masters, to give an account of the technical considerations which all painters are obliged to bear in mind.

One thing to be noted in a consideration of painting is that there is a wider divergence in the techniques employed than in that of any other art. We should not find this diversity so extensive if, instead of discussing the technique of oil painting, we were analysing the technical methods of the Primitives who painted with wax, yolk of egg, or in fresco. Whatever difference there may be in the appearance of a painting by Cimabue and one by Mantegna, it will be very much less than the difference between the work of two artists painting after the invention of oil painting.

It may not be necessary to recall that all the colours used in painting, whether they are of mineral or vegetable origin, finally appear in the form of more or less soft stones which are ground to a powder in order to be used. These coloured powders require some binding vehicle in order to bring them to a sufficient consistency. The vehicle may be wax, mortar, glue, glycerine or resin. The brothers Van Eyck are generally believed to have been the first to mix their colours with oil. From the numerous controversies to which their discovery has given rise, it would seem that the principal achievement of the brothers Van Eyck was that they perfected, for the purpose of painting easel pictures, the results of the much earlier practice which had been to use oil for the painting of large surfaces, and especially for the painting of boats. The effect of oil in rendering colours durable had been observed previously; pictures painted with yolk of egg had been covered with a coating of oil which was hardened by drying in the sun and which at once protected and intensified the colours.

Once, however, the practical method of grinding colours with oil had been discovered, a vast field of technical research opened up before painters, and they were naturally tempted to explore the new possibilities which were provided. It was this possibility of variety in technical methods which, in combination with the individual genius of the great masters, enabled the art of oil painting strictly so called to rise to such great heights at the time of the Renaissance.

The Support.—Oil paint will adhere to a number of materials, and during the ages painters have experimented in painting on a number of metal and mineral grounds. Slate, marble and alabaster have been used, but comparatively rarely owing to their fragility. Copper has also been utilised, though, of course, only for works of small size. Paper deserves special mention. Far from being an inferior material as might be supposed, paper is perhaps the most suitable ground for works of a spontaneous character. It was used by Flemish painters, who glued it to wood panels or canvases by means of casein. Later, in the 18th and early 19th centuries, a large number of French painters used this process, which was of great value in setting off their brilliant execution. No other material gives such transparency to browns or so much depth to blacks.

Practical considerations have, however, led most painters to prefer two supporting materials: first, wood, and second, canvas. Up to the end of the Renaissance period wood was generally employed; but it would be an error to suppose that the change to canvas was a sudden one. There are a number of examples of wood panels upon which a fine canvas has been glued. Besides, although the use of canvas became very frequent after the Renaissance, it cannot be said to have been universal, since at all periods in the history of painting, including the present, many artists have painted on wood. In Italy the white poplar was generally used; in Flanders they used oak. To-day mahogany, which does not crack so easily as oak, is often used.

Canvas appears to be the most suitable material for pictures of a large size. There are, however, exceptions, even among painters,

who habitually used canvas for their large works. Thus Rubens' *Magi* in the Antwerp Museum, one of the largest as well as one of the most admired compositions of that master, is executed on an enormous wooden panel formed by several transverse sections. Rubens' choice of a panel in this case and in others is not a mere chance. It may be laid down as an axiom that everything counts in the execution of a picture, and the support is not the least important factor in the final appearance of the work. It is an even more important factor in its preservation. Too much stress cannot, therefore, be laid on the importance of seeing that the support of the painting is of the best quality.

The history of painting shows so many examples of fine works which have perished that we must take every possible precaution to prevent damage to those which may be painted in the future. If wood is used, it must be carefully seasoned, thoroughly dry and cut radially, as otherwise it will be affected by changes of temperature and the picture will warp or split. If canvas is chosen, it should be of hemp, or better still of pure, unbleached flax fibre, without any admixture of cotton; this will prevent its being too liable to suffer from changes of temperature. It will easily be understood that if the tissue is constantly expanding and contracting the priming or the paint itself will be likely to scale off.

Preparation of the Support.—There is, however, another important matter to consider; the wood or canvas may be treated with a priming or used without. The latter method, which is the simplest, may be dealt with first without regard to chronology; for though it was occasionally used by old masters, such as Rembrandt and Van Goyen, it is in the main a modern practice. Many present-day painters prefer to dispense with priming, and this often gives good results, especially in painting on wood. If canvas is used the method has certain disadvantages, for contact with the oil renders the canvas brittle, and it thus loses the flexibility which is one of its principal merits.

Canvas, therefore, needs to be covered with priming before it is used, and the priming is, of course, an important factor. It has been the subject of extensive research from the time when it was first used. The basis of all priming is either size or casein mixed with plaster or carbonate of lime, or else a thin coating of white lead over a coating of size. These simple elements can be combined in a great variety of ways. Experiments with different kinds of priming have been tried at all periods of the history of painting. The Primitives used plaster and carbonate of lime for tempera painting, and this practice was continued long after the invention of oil painting. It was principally in the 17th century that it became customary to use white lead, more or less strongly tinted with grey, red or brown. A transitional method, which the present writer regards as excellent, was to cover the canvas with a thin coat of carbonate of lime, and then to complete the priming with white lead. Later, painters contented themselves with sizing the canvas and then covering it with one or two thin coatings of white lead. This process has become almost universal at the present day, but some painters are tending to return to plaster priming. It should never be forgotten that the principal quality which should be possessed by the priming of canvases is flexibility. Consequently the first coating of size which is placed over the canvas in order to fill up the interstices in the fabric must not be too thick, and if subsequent coats of carbonate of lime or white lead, or both of those materials in succession, are put on, they also should be very thinly applied. If the canvas is to dry well, it is better to apply several thin coats of priming than one thick one. It is extremely important to make sure that the canvas has dried properly. This is not always done with sufficient care before a picture is begun, and yet nothing is more dangerous than to use a canvas which has not dried properly. The dark colours will inevitably crack sooner or later. Industrially prepared canvases are often prepared without paying pre-consideration to the artist's requirements and so expose the paintings to accidents of this kind. This can be proved by a very simple experiment; take a piece of wood or canvas, and cover it with a coat of white lead; then, instead of waiting several months, as would be necessary if a picture were to be painted, paint on it patches of brown, madder lake, ultramarine and emerald green. These colours will rapidly crack; the first cracks will be noticeable on the emerald green after a few days only.

Colours and Their Preparation.—Colours, in the state in which they reached the painter when he prepared them himself, and in the state in which they now reach the manufacturer, are in the form of blocks, either crystalline or powdery, but generally of the consistency of soft chalk. Their quality undoubtedly depends above all on the purity of the raw materials used. The chemist isolates the colouring matter from the crude materials which he receives. In some cases the material is earth, as in the case of ochres; the earth is in its natural state in the case of yellow and red ochre, and it can be calcined so as to obtain other colours such as burnt sienna. Other colours are obtained from elementary materials; thus different kinds of black are produced from lamp black, bone charcoal and charcoal obtained from vine stocks. Ultramarine is also a natural stone—lapis lazuli. But unlike the coloured earths, which are abundant, natural ultramarine is so rare that it is scarcely used. By means of laboratory research a fairly stable blue resembling natural ultramarine has been obtained from sodium sulphide and silicate of aluminium.

It would be desirable if painters could use only colours extracted from simple sources such as earths. A colourist can do a great deal merely with yellow ochre, red ochre and black. These materials are little subject to alteration. Even the most skilful artist, however, cannot go far without the use of white; and this is the first stumbling block. The white which is known as flake white (in French, *blanc d'argent*) is a carbonate of lead, or in other words a purified form of white lead. It turns black in the course of time. The least that can happen is that it will turn yellow. Zinc white has not this disadvantage, but it cracks, does not spread easily and dries slowly. Moreover, even if the problem of the stability of white were solved, there would remain that of other colours which are absolutely necessary to the painter, such as bright yellow, whether strontian or cadmium, red, such as vermilion or even madder lake, blue, green and brown. These colours are the product of chemical combination and are only relatively stable. Some turn black, others absorb the colours mixed with them, while others become opaque.

However, not all of the hundreds of colours at the painter's disposal are equally bad. In order to choose the lesser of two evils, the painter should only add to the tones obtained from earths the indispensable minimum of other less durable colours.

Prussian blue, which was discovered in 1710 and was used to excess in the early 19th century, is today almost abandoned. Unless it is laid on as a light glaze, or supported by a considerable admixture of white, it tends to turn black and to absorb the colours mixed with it. A green composed of Prussian blue and a yellow (especially if this is not one of the earth yellows) gradually turns blue; similarly a violet into which Prussian blue enters gradually loses its red elements. Cobalt blue has the serious defect of appearing violet by artificial light.

It is possible to make a verbal distinction and to say that Rubens and Rembrandt did not use bitumen; they used a bituminous colour, and so did all the Dutch and Flemish painters; indeed all painters of whatever school have used a transparent brown resembling bitumen and fulfilling the same function; but it was recognised that the use of this colour was subject to certain strict technical conditions. At the end of the 18th century an attempt was made to recover the exact tone of bitumen which was believed to be that used by Rembrandt; it was believed to be very durable, and most of the painters of the day made abundant use of it. The terrible consequences are well known at the present time. The worst of it is that the damage due to bitumen, which never dries, combined with varnish which dries rapidly, may not become apparent until after many years.

The industrialisation of the manufacture of colours thus gives rise to a number of problems and technical points with which modern painters are unacquainted. They ought themselves to try experiments on the power of resistance of colours by exposing them to sunlight, and to fumes containing sulphur, sulphuretted hydrogen and ammonia; and in addition it would be in their interest to simplify their palette. Experience has shown, for

example, that Naples yellow becomes dull and greenish; that umber darkens and rapidly alters the colours mixed with it; that cadmiums lose their brightness in time; that ultramarine becomes opaque; that bitumen should only be used as a light glaze; and that colours which may be highly recommended must pass the test of time, and cannot be used with certainty until they have done so. It is only possible to calculate their palettes by making a close study of the old masters' pictures in a good light. It is possible to train oneself in a study of this kind by beginning with modern pictures. If the painting of a picture is closely examined, it is almost always possible to discern, in a single brush stroke, particles of the pure colours of which it is composed. If a study of several pictures by the same painter gives the same results, they may be taken as accurate.

A simple example may be found in the works of Pissarro; in all his pictures painted between 1878 and 1885 approximately, a mixture of Veronese green and ultramarine can clearly be distinguished. The use of these two colours during the period in question is thus established. This example has been selected because Pissarro obtains highly characteristic effects by this means. The remainder of his palette could easily be ascertained by continuing the analysis. Although, however, analysis may be simple in the case of the Impressionist school, it becomes more difficult as we go further back in the history of painting. The present writer frankly confesses that he cannot himself read the palette of all painters from their works. It is, however, possible to derive one general conclusion from a close study of the works of the great masters: that it is not necessarily the number of colours used which makes the colourist.

The grinding of the colours is a long and somewhat difficult business. It consists in pounding the powder, moistened with oil, until the grains are so fine as to be imperceptible. (*See* COLOUR MILLS.) This is done with a heavy muller, the under surface of which is as smooth as the slab of granite, on which the colours are ground. From time to time the grinder adds a few drops of oil. He has to continue kneading the paste until it is of the requisite fineness and consistency. It should be noted that a colour which reaches different grinders in the same state of chemical purity may not be of equal quality when it leaves their hands; the cleanliness with which the operation is carried out and the quality of the oil used affect the final result. The manufacture of colours is not a simple operation. Great practice is for example necessary to bring cobalt blue to the right consistency. Oil alone will not bind the paste sufficiently, and wax has to be added. The kind of oil used has its importance; olive oil, which was formerly much used in Italy because of its abundance, has now been given up because it dries slowly. Linseed oil on the other hand dries rapidly; copal oil is much esteemed by certain manufacturers; but poppy oil, which is light and colourless, is by far the most frequently used.

The painter should be able to use the paints in the form in which they reach him. He may use a siccative to make them dry more rapidly, but he should remember that this is an evil, even if a necessary one. He may use the colours in a thick paste, or slightly diluted, or as a thin wash; they are diluted with a quantity of oil, or turpentine, or a mixture of the two. It may be explained that the thin wash or glaze is composed of a transparent colour for choice, very much diluted, and its purpose is to heighten the value or activity of a tone which has already been laid on and has dried. Delicate effects and fine harmonies may be obtained in this way. The colours which are in practice used for this purpose are as a rule transparent yellows (Indian yellow, yellow lake, raw sienna and sometimes dark cadmium), nearly all the reds, but principally the lakes, black, nearly all the browns, and particularly bitumen. Although they have immense advantages, glazes have the defect of being liable to damage by the hand of time. They are slow in drying, and there is a risk that they may become incorporated in the varnish if the latter is applied too soon; and it must be admitted as an axiom that a picture will sooner or later have to be devarnished, and the painting itself should not be liable to injury when this happens.

A great number of prepared colours are now available; and while it is not necessary to give a list of them, it may be of use to mention a small number of specially durable colours with which a great variety of effects may be obtained. These are: flake white, golden ochre, strontian yellow, deep cadmium yellow, Venetian red, burnt sienna, cadmium red or vermilion, dark madder lake, ultramarine, cobalt blue, emerald green and ivory black or blue black.

This palette is only given as an example, since it would be arbitrary and useless to attempt to establish a uniform palette suitable to all temperaments. Some colours, too, may in themselves be injurious, and should be avoided as far as possible, but nevertheless may assist in creating the effect which is desired if they are used in the right place and with the necessary skill. For the nature of the colour itself is not the only factor; the manner in which it is used matters perhaps even more.

Brushes.—There are two kinds in general use, very different from one another; those made of sable hairs and those made of hogs' bristles. The latter are the most generally used. They consist of a metal collar which is generally flattened and keeps flat the bundle of bristles which form the brush itself. (*See* BRUSH: *in Art.*) The change from the round brushes, which were used until the 19th century, to flat brushes is due to the almost universal desire of the modern school to paint in separate touches with a full brush. The shape of the brush undoubtedly affects the nature of the stroke; but though it is difficult to describe the subtle difference made by the use of a round or a flat brush, because everything depends on the hand which uses it, it is easy to distinguish between passages executed with a sable brush and those executed with a hogs' bristle brush. The sable brush is better where precision of detail is required. The touch can be impasted and yet smooth, where bristle would not follow the exact intention of the painter with the same docility. Sable brushes are best for painting small pictures on panels, and for compositions where emphasis on detail gives the work part of its character. On the other hand it would be difficult to paint a life-size portrait or a large landscape with sable. The softness of the hairs would make it difficult to deal with a considerable quantity of paint, and the touch would be greasy and soft while a firm hogs' bristle brush would enable the painter to lay on a broad and vigorous surface.

Painters have at all times used their fingers and this use of the finger as a sort of flesh-and-blood trowel gave Courbet the idea of using the palette knife as a partial substitute for the brush. By using a flexible steel knife it is possible to obtain a vigorous touch and great variety of technique. It would of course be impossible to do any delicate drawing with the palette knife, but no instrument can be compared with it for preserving the purity of tones which often leave the palette fresh but are impaired by the time they reach the canvas. The palette knife can be wiped clean with a rag after each stroke; it represents an absolutely clean means of transferring the paint from the palette to the canvas, while only too often the brush is insufficiently cleaned and contains traces of all sorts of other colours. This does not however mean that the palette knife can take the place of the brush. The knife can only be used for certain restricted purposes, and for general use nothing can replace the brush. But everyone knows how important cleanliness is in the composition of colours, and it is only too often forgotten that the palette, the vessel which contains the vehicle, and the brushes, need careful attention because they are the last recipients of the colours, and colours cannot be beautiful unless they are skilfully used.

DEVELOPMENT OF THE ACTUAL PAINTING

We often hear it said that a picture has darkened or turned yellow. We are not here referring to the changes to which the varnish is subject, since although varnish gives the colours their maximum intensity, it does not form an integral part of the picture and will be dealt with only at the end of the article. What we now have to consider is the development of the paint which actually constitutes the picture.

Preparation of the Groundwork.—It has already been said that artists should give the utmost personal attention to the prep-

aration of their canvases. Upon the preparation of the groundwork the final aspect of the finished picture may depend. The old masters varied the priming of their panels or canvases according to the nature of the picture which they intended to paint. Rubens used a ground-work which was sometimes grey, sometimes tinted with ochre, sometimes greenish, and sometimes plain white as in the "Miraculous draught of fishes." Poussin used a grey ground-work for his "Autumn," and Boucher a pink-tinted one for his "Three Graces."

There is no doubt that the ground-work affects the painting which is superimposed on it. Let us suppose that two replicas of the same picture are painted, one on a yellow and one on a red canvas. After a few years the two pictures will be seen to differ from one another, and their general colour harmony will change, becoming nearer to that of the ground-work. A painter can thus, to a limited extent, plan in advance the future development of his picture, and should not neglect a factor which may add to its beauty later.

The desire to obtain rich colour harmonies must however always be subordinated to the numerous and complex exigencies of paint. Many pictures painted on light grounds have preserved an astonishing freshness down to the present day, while others painted on red, brown and even black grounds have suffered; indeed such paintings have generally worn badly, even if they were painted by Tintoretto, Poussin or Courbet.

The red grounds which so many painters have found attractive certainly make it easy to obtain a vibrant and transparent tone. But such a ground is of no value unless the paint itself is very lightly applied over it. And although the results may be satisfactory at first and may remain so for a number of years, the thin layer of paint which covers the coloured ground nevertheless gradually tends to disappear, and the tone of the ground begins to prevail over the others, thus putting out the colour harmony of the picture and destroying the balance of values; for, as will readily be supposed, the only parts which resist will be the high lights, which are generally painted in strong colours and which last all the better because they have probably been applied with fairly vigorous impasto in order to hide more completely the dark ground on which they were painted.

From the last observations we may at once draw a general conclusion which is of the greatest consequence to the painter: it must never be thought that the colours of a picture can be neutralized by the final layers of paint which are applied over them. A proof of this may be found in the curious phenomena connected with what are known in France as *repentirs*. These are corrections of a part of a picture which has already been painted, made before the whole picture is complete. If for example, at one of the sittings for a portrait, the artist sees that the arm or leg of his subject would produce a more characteristic effect if its position were changed, he may merely repaint the arm or leg without scraping off the original paint. Or again, accessories which prove inconvenient in the composition of a picture may be covered over with a few strokes of the brush. It often happens that after a longer or a shorter period the original detail begins to show through, and sometimes becomes quite clearly visible. This can be seen in Velasquez' portrait of Philip IV. in the Prado, in Ingres' "Jesus among the doctors" at Montauban, and in Bonington's "View of Venice" and Gros' "Portrait of the Comte Fournier-Sarlovèze" in the Louvre, to mention a few examples chosen haphazard from hundreds of others equally striking.

Development of Colours.—It is difficult to praise too highly the fertility of invention in colour harmonies and the bold experiments in technique which are due to the painters of the present generation. Only too often, however, these inventions contain an element of risk, and only too often, quite apart from the quality of the work, technical considerations are sacrificed. The creation of a picture makes great demands on the intellect, and in its execution, strict discipline must be observed; otherwise the paint in time takes its revenge.

Some painters, having carefully studied portraits by Titian and important pieces of painting by Tintoretto, in which those masters obtained astonishing effects simply by the use of four durable colours, white, black, yellow ochre and red ochre, have tried to reduce their palette to that basis, adding the minimum of additional colours when necessary. Some very good work has certainly been done by this method in the last few years. At the same time there are a number of pictures painted in this way which are heavy even when freshly painted, and which soon afterwards become painfully opaque. And yet, even leaving aside the Italian Renaissance, even leaving aside Velasquez, it is easy to show what variety can be obtained with this sober palette. It is only necessary to look at what has been done by men such as Manet, Corot in some of his figure subjects, Whistler, and Cézanne in his first manner.

There is however one often tested axiom which will give us one of the keys of the enigma: When the same colour, with the same value, is applied twice in the same place, the second application becomes opaque. It is owing to skilful organisation of their work that painters are able to include other colours in their palette besides the ochres, which, incomparably valuable as they are, have their limitations. For it has been proved that the best colours, if not cleanly applied, may lose their qualities, while others, which are not usually used, may be so employed that they will stand the test of time. No more typical example could be found than that of Veronese green. Too many painters use this colour in all circumstances, for it is very attractive owing to the variety of tones which can be derived from it. Unfortunately the effects which it gives do not last, and the subtlest harmonies, the most delicate greys, turn to a muddy and leaden black. Yet Gauguin constantly uses Veronese green without ill results. It should however be noted that Gauguin only employs this dangerous colour either pure or mixed with strontian yellow. Another example is that of vermilion, which loses its freshness and intensity in a few days unless it is applied boldly and without retouching.

Colours have characteristics of their own and however gifted an artist may be, he cannot dispense with patient observation of the difficult technical side of his art. In this respect, the best example in modern times is set by the Impressionists. If we take their best period, arbitrarily selecting 1890 as the final date, we shall find that their palette does not by any means consist of the most stable colours. The cadmiums and the madders play a much greater part than the earth colours, which the Impressionists did not use very frequently; but what admirable technical knowledge was shown by these painters, who were so long criticised for their revolutionary ideas! In their pictures we may note a light and luminous outline; the spots of colour are interlaced, but yet remain distinct. The colour effects are produced rather by the juxtaposition than by the mingling of tones, and it is left to the hand of time to blend and harmonise colours whose original bloom has been respected.

III. **Technique of Execution.**—A painter cannot with impunity retouch his picture whenever he feels inclined; a fact which only too many fail to realise, much to their detriment. The coloured paste which is transferred from the palette to the canvas is a fragile and capricious substance. To paint as inspiration and fancy dictate is not to paint soundly, especially if the work undertaken is on a large scale. Pictures completed at a sitting give the best account of the painter's talent. Everyone knows that studies for pictures are nearly always more brilliant than the completed work. A good example may be provided by a comparison between the female torso by Delacroix in the Musée d'Angers and the same passage as it appears in the "Sardanapalus" in the Louvre.

What can be done with a small picture, however, becomes much more difficult when it is desired to paint on a larger scale. Some masters have, nevertheless, in certain cases been able to paint large canvases without going back over what they had once begun; examples are Tintoretto's "End of the World" in the Madonna dell'Orto at Venice, and Franz Hals' "Banquet of the officers of the corps of archers at Saint-Georges," at Haarlem. By this means they attained an extraordinary vitality of colouring, and their works defy the passage of time. Spontaneous execution of this kind is, however, necessarily limited to certain effects; it is, for example, impossible to arrive all at once at all the pro-

VARIETY OF TECHNIQUE IN EXECUTION AND COLOUR

1. "A Woman Bathing," by Rembrandt van Rijn (1606–1669), Dutch. Rembrandt used glazes to add to the richness and luminous depth of the picture. 2. "The Three Graces," by François Boucher (1703–1770), French. Boucher here used a pink-tinted ground-work. 3. "The Judgment of Paris," by Peter Paul Rubens (1577–1640), Flemish. Rubens used glazes freely to add to the brilliance and charm of his colour. 4. "The Sleep of Antiope," by Correggio (1494–1534), Italian. In the Louvre. The glazes and half-tones have largely disappeared because of poor restoration in the 18th century. 5. "Portrait of Mme. Recamier" (unfinished), by Jacques Louis David (1748–1825), French. In the Louvre

VARIETY OF TECHNIQUE IN COLOUR AND LIGHT

1. Miracle of St. Mark (1548), by Tintoretto (Jacopo Robusti, 1518–94), Venetian School (The Academy, Venice). This artist was one of the first to project vast canvases in oil. He covered gigantic surfaces with rich oil colour, where fresco (on the fresh plaster) had been previously used as a medium
2. Landscape, by Nicolas Poussin (1594–1665), French. (The Prado, Madrid). Poussin used a canvas with a brown priming. His paintings have suffered accordingly and his landscapes are badly faded
3. The Bay of Baiae, with Apollo and the Sibyl, by J. M. W. Turner (1775–1851), English. Turner was fascinated with light, and uses colour with fluidity and brilliance. He greatly influenced the Impressionists
4. Adoration of the Magi, by Peter-Paul Rubens (1577–1640), Flemish. (Musée Royale des Beaux-Arts, Antwerp). This achievement unparalleled from the technical point of view is one of the largest and most admired of the master's compositions. It is executed on a large wooden panel, made up of several sections, directly over a ground-sketch in brown. Signs of the removal by the restorer of the vermilion and the old varnish appear below, right
5. Two Gentlemen, portrait of George Huddesford and of Codrington Warwick Brampfylde, by Sir Joshua Reynolds (1723–92), English. Reynolds worked with very long brushes, being thus enabled to see the effect of his work from some distance while laying on the colour. He often blocked in his pictures in *impasto* or *grisaille,* then coloured it and carried it further with glazes. His paintings evaporated, turned yellow, cracked, and perished even during his life time

VARIETY IN TECHNIQUE OF EXECUTION

1. "The letter" (*Le billet-doux*) by Jean-Honoré Fragonard (1732–1806), French. This illustrates dexterity of handling. Fragonard was one of the most brilliant sketchers ever known, equally notable for the virtuosity of his facile swift brushwork and for his pure, delicate colouring. He was a master of the sketch as a thing complete in itself
2. "Young woman with a jug" by Jan Vermeer of Delft (1632–75), Dutch. A great colourist, famous for his light effects, Vermeer achieved his smooth even handling with a round soft brush
3. "The Isle of Shoals" by Childe Hassam (1859–1935), American. Childe Hassam, as an Impressionist and a follower of Monet, frequently paints in the *pointilliste* method, with separate points or touches of pure colour, applied in conformity with the configuration of the surface to get the modelling. The whole scene vibrates with light
4. "Cannon Rock" by Winslow Homer (1836–1910), American. This painting of the Maine Coast series, sometimes called Homer's "Ocean Symphony," illustrates the artist's technical command of palette-knife and brush in the use of thick and thin paint

FAULTS AND DEFECTS OF PAINTINGS—ENLARGED VIEWS SHOWING DETAILS OF TECHNIQUE

1. "Head of a Girl," by Jan Vermeer of Delft (1632–75), Dutch. In the Royal Picture Gallery at The Hague. The cracks are caused by painting over a smooth priming. 2. "Portrait of M. Leblanc," by Jean Auguste Dominique Ingres (1780–1867), French. The cracks due to "Siccatif" are clearly visible. 3. "The Harvesters," by Pieter Bruegel the Elder (1525?–69), Flemish. Underpainting showing through an overpainted correction is known as a *pentimento.* Here the underpainting shows through, owing to the fact that the colours have become transparent from age. The tree trunk shows through the hat. 4. "Portrait of Philip IV," by Diego Velazquez (1599–1660), Spanish. In this famous portrait the original detail is beginning to show through and is clearly visible in places. In the Prado, Madrid

fundities of technique and observation which go to make up a Rembrandt; in such cases sketches must be made first.

Several methods of preparation have been and still are adopted. In order to retain as far as possible the impression of a picture executed without repainting, some masters have first sketched in their picture with a thin wash of a single colour, very much diluted. They thus mass in the lights and shadows and lay down the main lines of their subject, after which they attempt the final painting. This system was used for a great many 18th-century pictures in which the colours work in admirably with the original sketch executed in a reddish brown wash. An example is Fragonard's "Music Lesson," which has all the spontaneity of a rapid sketch.

Even before the 18th century Rubens, whose genius delighted in the overcoming of difficulties, was naturally attracted by this method. Not content with studies or simple compositions, he painted his "Kermesse" in the Louvre and his great "Adoration of the Magi" in Antwerp directly over a ground-sketch in brown. The latter work is an unparalleled *tour de force* from the technical point of view. But not all artists are Rubens, and a painter who does not possess his incomparable technical mastery cannot execute large-scale canvases by this method. There is, moreover, a danger; however vigorously the picture is painted, the colour in which the preliminary sketch is executed gradually tends to prevail in the general harmony. The result of this is indeed sometimes admirable; the "Portrait of Helène Fourment and her children" in the Louvre owes to its warm-tinted ground sketch a golden tone which is independent of the thick coat of varnish which has been applied.

Thus this attractive, but difficult and sometimes dangerous method, can only be used for limited purposes. It is more usual for painters to make use of all the materials at their disposal for sketching in their pictures; they use all the colours of their palette for the first groundwork, which matters so much to the success of the picture and still more to how it will develop in the future, and they gradually work up to the desired colour harmony. Great masters, such as Raphael, Chardin and Delacroix, have painted in this way. But they have never lost sight of the discipline which must be observed if a painting is to keep its pristine qualities. Like the sound technicians that they were, they did not forget the twofold danger which has to be avoided in the painting of a picture: overdone brushwork and muddy overlaid colour. A canvas painted without method is doomed to perish. If a sketch is painted over while it is only half dry, the paint will become muddy and dead; if solid colours, such as ochres, are applied over fragile groundwork painted with madders, or if a dark tone is put in over a light ground which is still fresh, cracking will result. What most often happens, however, is that one part of the canvas is painted over again to correct it without sufficient care; then all the dark parts become opaque black, while the lights lose their brilliance.

In order to avoid these dangers and to ensure good and solid quality in their paint, many painters work according to a system of division of labour. They use grisaille in the form of an undiluted paste for the preparation of their works, following a method first used by Italian Renaissance artists. Their pictures are sketched in with two colours, white and black or white and brown, as in a chalk and charcoal drawing. The painter can then, without any danger of working over the colour too much, work on a particular passage or modify the composition until the balance of the whole is satisfactory. The colour can then be put in on this solid foundation of grisaille; the final painting should be executed as rapidly as possible. This method has been used by Titian in his nudes and most of his portraits, El Greco and Rubens in many of their great works, Watteau in his "Gilles," Prud'hon in nearly all his pictures, and nearer to our own time Ricard and Gustave Moreau. Some painters go so far as to obtain their final harmony simply with glazes and a few touches of impasto over a monochrome ground; a typical example of this method carried to an extreme is to be found in Reynolds' "Portrait of Master Hare" in the Louvre. It will be observed that with this method the paint never becomes heavy, the colour may in some cases fade if it is put on too lightly, but no method of work does more to protect the delicate effects of a colourist or to preserve the unity of execution.

The Varnish.—The part played by varnish is twofold. In the first place it protects the picture from impurities in the air. In the second place it restores freshness to the picture when this has been lost, for as it dries, the oil which enters into the composition of the colours penetrates to the lower layers, as well as evaporates, leaving the colours dimmed. Varnish restores them to their original vigour, and it has the property of remaining transparent when it hardens. The theoretical value of varnish is thus simple and obvious. Its application is, however, often criticised. When painters leave the varnishing of their pictures to their colour dealers, and it is curious to note how many of them do, the dealer frequently puts on the varnish too thickly and irregularly. Pictures varnished in this way are painfully shiny, and as many modern painters give as much emphasis to their dark tones as to their high lights, it often happens that all the intersections of the dark strokes shine to such an extent that the picture cannot be properly seen. The first results of bad varnishing soon show themselves in the form of large stains on the picture corresponding to the irregularities in the application of the varnish.

Not only is varnishing sometimes badly done, but it is done too soon and at the wrong moment. Since varnish solidifies very quickly, it is quite obvious that it should not be applied until a painting is perfectly dry. This will prevent it from softening the paint even to the slightest extent, and thus causing it to crack by drying differently. Care should also be taken never to varnish a picture while it has dust on it; otherwise impurities will remain between the paint and the varnish and will in time spoil the picture. The coat of varnish should be extremely thin and applied firmly and regularly, since it loses its qualities and dries cloudy if it is put on thickly. Varnishing should not be done on a wet day, or moisture will be imprisoned between the varnish and the canvas. If this precaution is neglected, there will be a bluish film over the picture.

One of the most frequent stumbling-blocks for the painter is the result known as "matt" effect. The dulling of the paint, which has already been mentioned as one of the reasons for which varnish has to be used, may be produced while the picture is being painted, and will be especially marked if the first sketch is painted over before it is properly dry. The oil of the second coat may be absorbed so rapidly that the last touches which are put on appear to be of a dull grey nothing like the real colour. The "matt" effect at once disappears if any liquid is passed over the picture; but it often causes worse damage in the end, for the repeated imprisonment of moisture between the various layers of paint constituted by retouching will slowly but surely destroy the picture.

Siccatives, heavy oils and mixtures of all kinds are really responsible for much of the damage which is attributed to varnish. It is a matter of common knowledge that Delacroix was not always as strong on the technical side as he was lofty in his conceptions. It is difficult to say which did most to destroy his paintings—the curious mixtures of liquids which he used, or the disastrous qualities of the materials which entered into the composition of the colours with which he habitually painted. We can obtain some idea of the splendour which his works ought to have retained by looking at those canvases which he executed simply, such as the "Algerian Women," "The Artist's Studio" and the "Still Life" in the Moreau-Nélaton collection in Paris. And very often that delicate artist Prud'hon made excessive use of heavy oil and bitumen, which caused immense cracks to form in his pictures, as for example in his "Christ" in the Louvre.

How then, it will be asked, is it possible to correct a passage which is seen in the course of painting a picture to be unsatisfactory? And once the picture is painted, how can it be made fit for exhibition if it cannot yet be varnished without danger, and if the colours have a "matt" effect.

There are on the market a number of varnishes known as retouching varnishes, the merits or demerits of which cannot be discussed here. It may, however, be said that the lighter and more transparent the liquid to be applied over the piece which it

is desired to repaint, the less danger there is that it will impair its freshness in time to come.

When the painting is completed, the general effect can be clearly seen if it is washed over with a mixture of white of egg, water and sugar. This preparatory varnish does not affect the colours in any way, and it can be sponged off with water when the time comes, about a year later, to apply the final coat of varnish which it has by this means been possible to defer.

Some have thought that varnish can be replaced by glass, and many have followed the example of the British picture galleries by glazing oil paintings. Glass is an effective protection against damp, especially if the back of the picture is felted. This is the reason why it is used in London, where the air is very damp. At the same time glass protects the picture from the fingers of clumsy visitors to public galleries, and from smoke in private houses. But it can never be a substitute for varnish; indeed it often makes it impossible to see and appreciate a picture properly. Not only is glass no substitute for varnish, but it transforms the picture into a mirror, so that the spectator sees a reflection of himself rather than the painting.

The disadvantages of glass are not so serious in the case of pictures in which the general tone is light. The difficulty still exists, but it is lessened because white does not transform a sheet of glass placed in front of it into a mirror. Many modern painters who paint in light tones have refrained from varnishing their pictures, as it does not help very much to bring out light tones. The objection to varnish dates, naturally enough, from the Impressionist period. The Impressionists wished their colours to produce as vibrant an effect as possible, and they therefore took care not to cover the paint with a foreign substance which was liable to develop in a way which they did not like.

It was inevitable that as painters gave up the use of varnish, they should gradually come to use turpentine to dilute their colours, and at the same time to paint on absorbent canvas. Mat painting has the technical advantage of avoiding the difficulty of "bloom" which was mentioned above; a deliberate attempt is made to obtain harmonies by the use of colours which do not shine because they contain less oil, either on account of their having been mixed with turpentine or on account of the oil having been absorbed by the canvas. So many admirable works have been produced by this method that we cannot fail to rejoice at a new discovery in the technique of painting. It must, nevertheless, be asked in all impartiality how a painting from which for one reason or another varnish has been excluded will stand the effects of time. If pictures were always to be exhibited under favourable circumstances, in a dry climate, not exposed to changes of temperature, and sheltered from dust, smoke and fumes of all kinds, we could allow varnish to be an unnecessary protection. All persons who have had occasion to see a large number of paintings will, however, have met with cases, somewhat rare, it is true, of 18th century decorative panels which have never been varnished. As a general rule about one centimetre of the edge of the painting is concealed by a frame or beading. The painting has not turned yellow as it would have done if it had been too heavily varnished, but at the same time it has not kept its original brilliance; it is covered, as it were, with a veil of warm grey except under the frame, where it has been protected from the light and from the impurities in the air and has preserved its original freshness. The worst feature is that there is no way of cleaning pictures of this kind. The dust fixed on the paint by the moisture in the air has become incorporated with it; but still more, the very body of the colour has been affected. Simple tones such as light greys have remained comparatively luminous, but the reds have become purplish, the yellows have turned brown, and the browns have lost their transparency. The dirt produced by dust fixed on the picture by the moisture of the air has worked right into the grain of the canvas. Such attacks by foreign bodies would not have had so much effect on varnish, and even if owing to circumstances the varnished picture had suffered an accumulation of dirt, it would still be possible to remove the varnish and find underneath the picture as the painter conceived it.

It is most desirable to protect these mat pictures with glass, unless a coating of wax is put over them to preserve their nonshiny appearance. The merits of wax for this purpose have always been known; it is one of the best means of preserving paintings, and it isolates them from injury from without in the same way as varnish.

OIL PALM, a genus of palms (*Elaeis*) botanically allied to the coconut palm (*Cocos*). The more widely known of the two species belonging to the genus *Elaeis*, *E. guineensis*, is indigenous to tropical West Africa, where it has attained considerable economic importance as a source of palm oil and palm kernels, but it is also cultivated as a plantation crop in Indonesia and Malaya and, on a small scale, in some Central and South American countries. The oil palm in Africa is confined mainly to a 300-mi.-wide region along the coast from the Gambia to Angola, although it is also found in the forest regions of the middle Congo and British East Africa. It is a light-demanding species but grows well on a variety of deep, well-drained, neutral or alkaline soils. In maturity it may attain a height of 60 ft. but normally has a stem of no more than 30 ft., which bears at the summit an irregular crown of feathery leaves, each of from 10 ft. to 15 ft. in length and pinnately divided into 50 or more lance-shaped leaflets. The numerous flowers are crowded on a short spadix and develop into a large ovate fruit cluster which may contain more than 1,000 drupes, varying in colour from a deep yellow to a dark red-brown. Mature palms bear from two to six bunches of fruit, each normally weighing between 10 lb. and 35 lb., approximately one-third of which consists of stems or bracts.

The individual fruit is between 1 in. and 2 in. in length and ¾ in. and 1 in. in diameter, its weight varying from 3 g. to 25 g. The fibrous pericarp, or outer fleshy portion of the fruit, consists, as to between 30% and 70% of its weight, of palm oil, while the kernels in the endocarp are approximately 50% by weight of palm kernel oil.

The weight ratio of pericarp to kernels varies considerably but the *dura* and *tenera* varieties cultivated in Malaya and Indonesia consist largely of pericarp, unlike the wild palms (var. *macrocarya*) of West Africa; production of palm oil in the Asian countries is consequently of much greater importance than that of palm kernels (*see* PALM OIL). Research into the improvement of *E. guineensis* strains has been concentrated mainly upon the thick pericarp varieties and, in particular, upon dwarf varieties which facilitate harvesting of the fruit.

See West African Institute for Oil Palm Research, *Quarterly Progress Report* (Benin City, 1953). (H. F. C. G.)

OIL REFINING: *see* PETROLEUM.

OIL RESERVES SCANDALS (U.S.). Certain oil-

bearing lands in the state of California—reserve no. 1 (Elk Hills) and reserve no. 2 (Buena Vista)—had been designated by the U.S. government in 1912 as naval oil reserves. Three years later reserve no. 3 (Teapot Dome, Wyo.) was established.

The navy department was authorized in 1920 to exploit and use those lands on the reserves on which there were no prior claims pending. Although the navy department retained the right to set general policy, jurisdiction over the reserves was later transferred by executive order to the department of the interior.

In 1922 the secretary of the interior, Albert B. Fall, and the secretary of the navy leased the Elk Hills reserve to Edward L. Doheny of the Pan American Petroleum company, and the Teapot Dome reserve to Harry F. Sinclair of the Mammoth Oil company. The negotiations were carried on in secrecy on the advice of the navy department, which held that military plans and security were involved since the construction of oil tanks at Pearl Harbor, T.H., and other strategic matters were part of the agreements.

Senate investigating committees, however, discovered that Fall had received a "loan" of $100,000 from Doheny and was further involved in financial dealings with Sinclair.

A joint resolution was passed by the U.S. congress on Feb. 8, 1924, directing the president "to institute and prosecute suits to cancel certain leases of oil lands and incidental contracts, and for other purposes."

The resolution stated: ". . . the said leases and contract are against the public interest and . . . the lands embraced therein should be recovered and held for the purpose to which they were dedicated." It was further resolved that "the President of the United States be, and he hereby is, authorized and directed immediately to cause suit to be instituted and prosecuted for the annulment and cancellation of the said leases and contract and all contracts incidental or supplemental thereto, to enjoin further extraction of oil from the said reserves under said leases or from the territory covered by the same, to secure any further appropriate incidental relief, and to prosecute such other actions or proceedings, civil and criminal, as may be warranted by the facts in relation to the making of the said leases and contract."

After a great deal of litigation, the courts held the leases invalid. In criminal actions Doheny and Sinclair were acquitted of charges of bribery and conspiracy, but Fall was convicted and served a prison term.

(*See* also SECRET SERVICE, U.S.; UNITED STATES: *History: After World War I—To 1926*.)

OILS, FATS AND WAXES. The term "oils" is loosely used as a generic term for substances having the common property of being greasy fluids, either at the ordinary temperature, or at temperatures below the boiling-point of water. Formerly, when substances were principally classified by obvious characteristics, the word included such a body as "oil of vitriol" (sulphuric acid), which has, of course, nothing in common with what is now understood under the term oils.

In its most comprehensive ordinary acceptation the word embraces at present the fluid, "fixed," or fatty oils (*e.g.,* olive oil), the soft fats which may be fluid in their country of origin (*e.g.,* coconut oil, palm oil), the hard fats (*e.g.,* tallow), the still harder vegetable and animal waxes (*e.g.,* carnaüba wax, beeswax), the odoriferous ethereal (essential) oils and the fluid and solid volatile hydrocarbons—mineral hydrocarbons—found in nature or obtained from natural products by destructive distillation, (petroleum, shale oils, oils from the low-temperature distillation of coal).

The importance of fatty and mineral oils to the life and industry of a nation is a commonplace of everyday observation; the exigencies arising from the World War did but emphasize human dependence on these raw materials for food and power, and stimulated development and research in all branches of the industries connected with them. Great advances have been made in the utilization of mineral (petroleum [*q.v.*]) oils. The last two decades have seen great developments in oil-fuelled internal combustion engines and the widespread adoption of oil as a fuel for steam-raising, both in stationary boilers and for shipping, and more especially for battleships, where high power output combined with economy in fuel-storage space and stokehold labour are of primary importance. Improvements in the production of lubricating oils have been necessitated by the advances in modern machinery, which involve higher working temperatures and pressures. We may note in passing the development, especially in Germany, probably as a direct result of war-time isolation from supplies of mineral oils, of the production of oils by the distillation of lignites and by synthesis from producer gas.

The fatty oils, ever of paramount importance as food, acquired an increased significance during the War as sources of glycerine, the basis of explosives of the dynamite class. In England, strict government supervision was exercised over soap manufacture, and all industries involving the hydrolysis of fats, to ensure the maximum recovery of glycerine (about 10–14% of the weight of a fresh oil). Towards the end of the War period a process was mooted to replace the glycerol in edible fats by mannitol or a similar sugar, in order to obtain both the glycerine and a product equal in nutritive value to the original fat.

The shortage of edible oils in all countries during the War led to great advances in the technique of oil-refining; oils hitherto regarded as purely industrial became available for food as a result of improved methods of purification, and it may be said that to-day almost all fats, with the exception of those possessing marked physiological action, such as castor, curcas and chaulmoogra oils, can be utilised as food. Especially in the Central European countries, where, as a result of the blockade, the shortage of fats became acute, every effort was made to stimulate the investigation and production of synthetic fats. In some cases processes were put into actual operation; and in Germany attempts were made to supplement available resources with fat obtained from yeast under intensive cultivation. Synthetic fatty acids can be prepared by the oxidation of paraffin wax and other hydrocarbons, and glycerides have been synthesised on the large scale by heating these acids, under pressure, with glycerol, which may be obtained by the fermentation of non-crystallisable sugars. In view, however, of the enormous expansion of which the natural production of the fats is capable, it is extremely improbable that these methods will be commercially successful under normal economic conditions.

The common characteristic of all the "oils" is that they consist principally, in some cases exclusively, of compounds of carbon and hydrogen. They are all readily inflammable and are practically insoluble in water. The mineral hydrocarbons found in nature, or obtained by destructive distillation do not come within the range of this article (*see* NAPHTHA, PARAFFIN, PETROLEUM), which is restricted to the following two large groups of bodies, formed naturally within the vegetable and animal organisms, viz. (1) Fixed oils, fats and waxes, and (2) Essential, ethereal or volatile oils.

FIXED [FATTY] OILS, FATS AND WAXES

The substances to be considered under this head divide themselves naturally into two large classes, viz., fatty (fixed) oils and fats on the one hand, and waxes on the other, the distinction between the two classes being based on a most important chemical difference. The fixed oils and fats consist essentially of *glycerides, i.e.,* esters formed by the union of three molecules of fatty acids with one molecule of the trihydric alcohol *glycerol* (glycerine, *q.v.*).

In a class of glycerides known as the phosphatides or phospholipines one or more of the fatty acid radicles is replaced by a grouping containing nitrogen and phosphorus, as, for example, lecithin.

The waxes consist of esters formed by the combination of one molecule of fatty acid with one molecule of a monohydric alcohol, such as cetyl alcohol, cholesterol, etc. Only in the case of the wax *coccerin* are two molecules of fatty acids combined with a dihydric alcohol. It must be pointed out that this distinction does not find ready expression in common parlance; thus *Japan wax* is a glyceride and should be more correctly termed Japan tallow, whereas *sperm oil* is, chemically speaking, a liquid wax. Although these two classes of substances have a number of physical properties in common it is better, for some purposes, to consider them

under separate heads. The true chemical constitution of oils and fats was first expounded by the classical researches of Chevreul, embodied in his work, *Recherches sur les corps gras d'origine animale* (1823, reprinted 1889).

Occurrence.—The oils and fats cannot be looked upon as definite chemical individuals, but as representatives of natural species which vary, although within narrow limits, according to the climate and soil in which the plants producing them are grown, or, in the case of animal fats, according to the climate, the race, the age of the animal and especially the food as well as the idiosyncrasy of the individual animal. The oils and fats are distributed throughout the animal and vegetable kingdom, from the lowest organisms to the highest, and are found in almost all tissues and organs. The vegetable oils and fats occur almost exclusively in the seeds and fruits; the waxes appear usually as thin films covering leaves and fruits. In animals the fats are enclosed mainly in the cellular tissues of the intestines and of the back, although a certain amount of fat is present in all the organs; in the lower animals fat is also stored in the liver, muscles, etc. There are a few liquid waxes known, occurring in the blubber and head cavity of sperm whales and stored in the stomach of certain arctic and antarctic birds (*e.g.*, Australian mutton-bird [*see* SHEARWATER]); other waxes occur as insect secretions, while wool-wax is the natural grease found in sheep's wool.

Physiology of the Fats.—The most evident function of the fats in animal organisms is that of food-reserve, to supply, by subsequent oxidation, energy for the growing and working tissues. The storage of fats and oils in vegetable seeds can be similarly explained as food-reserve for the embryo; it is difficult, however, to account for the presence of oil in large quantities in the pericarp of fruits such as the olive and palm, which is probably destroyed before germination of the seed. The fats, and especially the waxes, can fulfil other valuable service by virtue of their physical properties, *e.g.*, insolubility in water, and their chemical inertness. For instance, subcutaneous fat deposits protect the organism from cold; beeswax prevents dilution of the concentrated sugar solutions of the comb by external moisture; the waxes, and in some cases the fats, secreted in the leaves of plants preserve the underlying tissues from loss or access of water. It is probable that the resistant powers of the tubercle bacillus are largely attributable to the protective effect of the wax coating in which it is encased; this waxy secretion is remarkably inert and resists the action of the usual hydrolysing measures. It is probable that the fats fulfil still other, though more recondite, essential functions, quite distinct from their office as fuel supply for the cells.

It is only within the last few years that the importance of the animal fats as sources of the fat-soluble vitamins has been recognised: the discovery that vitamins (*q.v.*) may be produced in some non-active vegetable oils by the action of light is among one of the most recent advances of biochemistry. These bodies, of vital physiological importance as accessory growth factors, appear in minute proportions in the unsaponifiable (non-glyceridic) fraction of natural oils probably as a result of their physical solubility in these media; nevertheless the recognition of the part played by these substances attaches a new significance to the rôle played by the fats in animal metabolism.

Synthesis and Oxidation of Fats in Living Organisms.—The fat of the flesh-eating animals appears to be mainly derived from the fats consumed in the food; it has been demonstrated, however, by the classical researches of Lawes and Gilbert, that animal fats can be derived from carbohydrate food, while it is probable, although the proof is not so clear, that carbohydrates are the source of the fats in herbivorous animals and plants. In the case of vegetable seeds and fruits the formation of fats occurs late in the ripening process; in the unripe condition carbohydrates (sugars, starches, etc.) are to be found in the fruits and sap, but no fatty acids (or oils) and it is likely that the former are broken up and converted into fatty acids and subsequently into glycerides during the maturing process. In the case of almonds it has been observed that carbohydrates disappear as fat is formed.

It is a noteworthy fact that, almost without exception, only acids with an even number of carbon atoms in the molecule occur in the natural fats. The preponderance of C_{18} acids suggests the hypothesis that the fats are derived from the C_{18} nucleus of the polysaccharides, or, perhaps, from three molecules of glucose. Secondary oxidations and condensations are necessitated to explain the formation of C_{16} and the higher acids C_{20}, C_{22} and C_{24}. To account for the formation of milk fats and fats of the coconut class, which are distinguished by the presence of the lower fatty acids, a second type of synthesis has been postulated, involving a building-up process of the acids, one from another, and originating from simple sugars instead of the more complex polysaccharides. Yet other theories have been propounded to account for the formation of the unsaturated link in the middle of the oleic acid chain. It is possible that fats can be formed from protein material.

The utilisation of the stored fat by the plant embryo has been but little studied; it seems that the fat is hydrolysed by lipolytic (fat-splitting) enzymes and broken down, possibly into simpler fatty acids, with the ultimate production of carbohydrates (*cf.* conversion of fat into sugars in animals under abnormal conditions of glucosuria).

In the animal body the fats of the food are emulsified and hydrolysed by enzymes in the intestine; the glycerol and fatty acids are absorbed through the intestinal epithelium, recombined to form glycerides characteristic of the animal in question and transported *via* the blood and chyle to the connective tissues for storage. It may be noted that the fat of an individual animal can vary according to the fatty food supplied; for instance, the milk-fat of cows fed on a diet rich in coconut-oil simulates the latter in its properties; the fat of the Eskimo possesses an abnormally high iodine value, and resembles blubber oil.

The way in which the fat reserves are circulated to the organs in which combustion of the fat with the liberation of energy occurs, is scarcely understood. It is established that when mobilisation of reserve fat takes place the stream is primarily directed to the liver, where the fatty acids are desaturated, *i.e.*, unsaturated linkages are introduced into the fatty acid molecules. It is uncertain whether unsaturated acids so produced are distributed to the working cells as glycerides; it is possible that compounds of the fatty acids with nitrogen and phosphorus (the phospholipines, which are found in the liver and other organs) must be built up by the liver prior to transfer by the blood to the various organs. The unsaturated links introduced into the fatty acids by the liver appear to provide weak points for attack by the working cells in the process of combustion to the ultimate products of carbon dioxide and water.

FATTY OILS AND FATS

The fixed oils and fats form a well-defined and homogeneous group of substances passing through all gradations of consistency, from oils which are fluid even below the freezing point of water, up to the hardest fats which melt at about 50° C. Therefore, no sharp distinction can be made between fatty oils and fats. Nevertheless it is convenient to apply the term "oil" to those glycerides which are fluid below 20° C, and the word "fat" to those which are solid above this temperature. As a general inclusive term the expression "fat" is preferable, since this avoids confusion with mineral and essential oils.

Chemical Composition.—No oil or fat is found in nature consisting of a single chemical individual. Following on Chevreul's work, the fats were considered to consist in the main of mixtures of "simple triglycerides," this is, of *glycerides* in which each molecule of *glycerol* is combined with three molecules of the same acid, *e.g.*, tristearin, $C_3H_5(O{\cdot}CO{\cdot}C_{17}H_{35})_3$, the glyceryl ester of stearic acid, $C_{17}H_{35}COOH$; triolein, $C_3H_5(O{\cdot}CO{\cdot}C_{17}H_{33})_3$. Recently, however, it has been shown that "mixed glycerides," *i.e.*, compounds wherein one molecule of glycerol is united with two or three different fatty acid radicles, preponderate, *e.g.*, dipalmito-stearin, $C_3H_5(O{\cdot}CO{\cdot}C_{15}H_{31})_2(O{\cdot}CO{\cdot}C_{17}H_{35})$; palmito-oleo-stearin, $C_3H_5(O{\cdot}CO{\cdot}C_{15}H_{31})$ $(O{\cdot}CO{\cdot}C_{17}H_{33})$ $(O{\cdot}CO{\cdot}C_{17}H_{35})$. The natural fats, therefore, may differ, firstly in the fatty acids which they contain, and, secondly, by the different arrangement of the acids in simple and mixed glycerides. Fatty diglycerides only

occur occasionally as products of partial hydrolysis of the oil by ferment action.

Fatty Acids.—The most important and widespread of the fatty acids are *palmitic*, $C_{15}H_{31}COOH$ and *stearic*, $C_{17}H_{35}COOH$, acids (of the saturated series), and the unsaturated *oleic* acid, $C_{17}H_{33}COOH$.

The fatty acids are classified into related (homologous) series according to their degree of unsaturation, *i.e.*, the number of unsaturated or ethenoid bonds $>C=C<$, in the molecule of the acid. This classification is amplified in the list of examples which here follows.

Straight chain fatty acids.—The acids of the saturated (*acetic*, or *stearic*) series, general formula $C_nH_{2n+1}COOH$, include among the lower members butyric acid, C_3H_7COOH, characteristic of butter fat (*q.v.*), caproic, $C_5H_{11}COOH$, caprylic, $C_7H_{13}COOH$, capric, $C_9H_{19}COOH$, lauric, $C_{11}H_{23}COOH$, and myristic acids, present in butter and fats of the coconut class; stearic and palmitic acids are higher in the series. Acids of the oleic series, $C_nH_{2n-1}COOH$, (one pair of doubly-linked carbon atoms), of which oleic acid $C_{17}H_{33}COOH$, present in nearly all oils and fats, and erucic acid $C_{21}H_{41}COOH$, characteristic of rape and fish oils, are the most important. Acids of the linoleic series, $C_nH_{2n-3}COOH$ (two ethenoid bonds), include linoleic acid, $C_{17}H_{31}COOH$, present to a large extent in maize and cottonseed oils. The linolenic series acids, $C_nH_{2n-5}COOH$ (three double bonds) of which linolenic acid, $C_{17}H_{29}COOH$, the characteristic acid of linseed oil is very important, as the high degree of unsaturation of this acid is responsible for the "drying" power or oxidisability upon which the commer-

TABLE I.

Oil	Principal sources of raw material	Yield %	Iodine value	Principal applications
		Vegetable Oils		
Drying oils				
Linseed	Argentina, India, N. America, Russia	38–40	175–205	Paint, varnish, linoleum, soft soap.
Tung	China, Japan	40–41	150–165	„ „
Hempseed	W. Europe, N. America, India, Japan	30–35	148	„ „ soft soap, rubber substitute.
Poppyseed	Levant, India	41–50	123–143	Salad oil, artists' oil, soft soap.
Semi-drying oils				
Soya bean	China, Japan	13–17	122	Edible, burning.
Maize; corn	U.S.A., Argentina	6–10	113–125	„ soap.
Cottonseed	„ India, Egypt	30–32	116	Food, soap, steel-plate industry.
Sesame	India, etc., Egypt, Levant	24–26	108–110	„ „
Rape (Colza)	E. India, Europe	33–43	94–102	Food, lubricant, burning, wool oils, steel-plate industry.
Non-drying oils				
Almond	S. Europe, N. Africa	45–55	93–100	Perfumery, pharmacy.
Arachis (ground-nut)	India, W. Africa, China, U.S.A.	43–45	83–100	Edible, soap.
Olive	Mediterranean countries	40–60	79– 88	„ , soap, perfumery; lubricating, pharmacy.
Castor	E. India, Mediterranean, C. America	46–53	83– 86	Medicine, soap, lubricant, Turkey-red oil.
		Animal Oils		
Marine Animal Oils

Butter	N.W. Europe, Australasia, Canada	..	26–38	Food.

cial application of the oil in the paint industry depends. Still more unsaturated acids occur, such as clupanodonic acid, $C_{21}H_{33}.COOH$ (five ethenoid bonds), typical of fish, liver and blubber oils. The oxidation products of these oils, however, do not form such tenacious films as linseed oil, to which they are much inferior as paint oils. The hydroxylated acids of the ricinoleic series, $C_nH_{2n-2}(OH)COOH$, are typified by ricinoleic acid, $C_{17}H_{32}(OH)COOH$, the occurrence of which is responsible for the solubility of castor oil in alcohol.

The occurrence of *cyclic* (closed chain) acids is confined to oils of the chaulmoograc and hydnocarpus family. Acids with more than 22 carbon atoms in the molecule are rare among the fats, but are of fairly frequent occurrence among the waxes.

Unsaponifiable Matter.—Since the methods of preparing the vegetable and animal fats are comparatively crude, they usually contain certain impurities of one kind or another, such as colouring and mucilaginous matter, remnants of animal and vegetable tissues, etc. For the most part these foreign substances can be removed by processes of refining, but even after this purification the fats still retain small quantities of foreign bodies, such as traces of colouring matter, albumenoid and (or) resinous substances and other nonglyceridic compounds; these substances can be isolated only after saponification of the fat and are comprised in the term "unsaponifiable matter." Included among the unsaponifiable matter are the *sterols* (cyclic alcohols) —*phytosterol,* $C_{27}H_{46}O$, *sitosterol,* $C_{27}H_{46}O$, *stigmasterol,* $C_{30}H_{48}O$, *ergosterol,* $C_{27}H_{42}O$—and the animal sterols—*cholesterol,* $C_{27}H_{46}O$, *coprosterol,* $C_{27}H_{48}O$, etc. Phytosterol (*i.e.,* plant sterol) occurs in all oils and fats of vegetable origin; cholesterol is characteristic of all oils and fats of animal origin. This important difference affords a means of distinguishing by chemical methods vegetable oils and fats from animal fats. It is in the unsaponifiable fraction of oils that the bodies known as the fat-soluble vitamins (*q.v.*) have been located; these appear to be substances related to the sterols; for example, it was clearly demonstrated that vitamin D can be produced from inactive ergosterol by irradiation with ultra-violet light.

The amount of unsaponifiable matter in an oil or fat does not, as a rule, exceed 2%, but in the case of some shark-liver oils the proportion is abnormally high, as large quantities (up to 85%) of highly unsaturated hydrocarbons such as spinacene and squalene ($C_{30}H_{50}$?) are present; the relationship of these bodies to the glycerides normally occurring in oils, including fish-body oils, is a matter for research.

Classification.—Following subdivision into animal and vegetable oils and fats, a second guiding principle to classification is afforded by a consideration of the amount of iodine the various fats are capable of absorbing. This is a measure of the unsaturated acids present, since iodine is absorbed (under suitable conditions) at the ethenoid linkages of the molecule of fatty acid.

About 80 of the natural fats are commonly utilized to a greater or less extent; the annual world consumption of each of about 20 of these approaches or exceeds 100,000 tons, and in the case of about 6 is in the neighbourhood of 1,000,000 tons. They are classified as follows:

Solid Vegetable Fats.—These are found mainly in the kernels and seeds of tropical fruits. They melt at from 20° to 35° C. and contain in general but little combined oleic acid, the bulk of the component fatty acids being lauric, myristic and palmitic. Fruits of many of the palm family, notably coconut oil and palm kernel oil, contain very large amounts of combined lauric acid. Palm oil contains chiefly palmitic and oleic glycerides. All these fats, when suitably refined, are used for edible purposes, and many are used in the manufacture of the higher grades of toilet and other soaps.

Solid Animal Fats.—A most important group of animal fats is that of milk fats, which are used universally as butter. All milk fats are characterized by the presence of definite, if relatively small, quantities of fatty acids which are known respectively as butyric, caproic and caprylic acids.

Physical Properties.—The specific gravities of oils and fats range from 0.913 (rape oil) to 0.975 (Japan wax, myrtle wax); for the bulk of the fats the value is between 0.915 and 0.945. Some oils, notably those of the castor oil and chaulmoogra groups, rotate the plane of polarization of light.

The oils and fats are practically insoluble in water; with the exception of oils of the castor oil group they are insoluble in cold, and only sparingly soluble in boiling, alcohol. They are completely soluble in ether, carbon disulphide, chloroform, carbon tetrachloride, petroleum ether and benzene. Oils and fats have no distinct melting or solidifying point; this is not solely due to the fact that they are mixtures of several glycerides, for even pure glycerides exhibit the phenomenon of a "double melting point." The freezing points of the oils range from a few degrees above zero down to −28° C. (linseed oil). At low temperatures (*e.g.,* at 12° C. in the case of cottonseed oil), solid portions, usually termed "stearine," separate out from many oils. These solid portions can be filtered off; the filtrates constitute the commercial "demarginerated oils" or "winter oils" which will remain limpid at low temperatures.

Oils and fats can be heated to a temperature of 200° to 250° C. without undergoing any material change, provided prolonged contact with air is avoided. On being heated above 250° up to 300° C. some oils (*e.g.,* linseed oil, safflower oil, tung oil [*q.v.*] [Chinese or Japanese wood oil] and even castor oil) undergo a change, probably caused by polymerization, resulting in the formation of semisolid or solid products. Above 300° C. fats are decomposed; this is evidenced by the evolution of acrolein (a decomposition product of glycerin), which possesses the pungent odour of burning fat. Hydrocarbons are formed at the same time (*see* PETROLEUM).

On exposure to the air oils and fats gradually undergo certain changes. The *drying* oils absorb oxygen ("dry") somewhat rapidly, thin layers forming a skin or film. Extensive use of this property is made in the paint and varnish trades. The *semidrying* oils absorb oxygen more slowly than the drying oils and are, therefore, useless as paint oils; still, in course of time, sufficient oxygen is absorbed to produce distinct thickening. The oxidation of the semidrying oils is accelerated by spreading such oils over a large surface, notably over woollen or cotton fibres, when oxygen absorption may proceed so rapidly that spontaneous inflammation ensues. Many fires in cotton and woollen mills have been caused in this way. The *nondrying* oils, of which olive oil is typical, do not become oxidized readily on exposure to the air, although gradually changes take place, including slow hydrolysis (splitting to fatty acids and glycerol) and subsequent oxidation; the oils thicken slightly and acquire the peculiar disagreeable smell and acrid taste defined by the term "rancidity." The chemical reactions involved in the development of rancidity have not yet been fully explained. If the action of the air and moisture is allowed free play, the hydrolysis of the oils and fats may become so complete that only the insoluble fatty acids remain, the glycerol being washed away. This is exemplified by *adipocere* (corpse fat) and also by Irish bog butter, which consists chiefly of free fatty acids.

The property of the fats of being readily hydrolyzed is most important, and extensive use of it is made in the arts (soap making, candle manufacture, etc., and recovery of their byproducts). If treated with water alone under high pressure (corresponding to a temperature of about 220° C.), or in the presence of water with caustic alkalies, alkaline earths or basic metallic oxides (which act as catalyzers), at lower pressures, they are converted in the first instance into free fatty acids and glycerol; *e.g.,* if bases sufficient in amount to combine with the fatty acids be present, the corresponding salts of these acids are formed, such as the sodium salts of fatty acids (hard soap) or potassium salts (soft soaps), soaps of the alkaline earths (lime soap) or of the metallic oxides (zinc soap), etc. For detailed descriptions of the methods employed in commercial hydrolysis, *see* CANDLE; SOAP.

Extraction.—Since the oils and fats have always served the human race as one of the most important articles of food the oil and fat industry may well be considered to be as old as the human race itself. The methods of preparing oils and fats range

themselves under three heads: (1) Extraction by "rendering," *i.e.*, boiling out with water; (2) extraction by expression, and (3) extraction by means of solvents.

Rendering.—The crudest method of rendering oil from seeds, still practised in Central Africa, in Indo-China and on some of the South Sea Islands, consists in heaping up oleaginous fruits and exposing them to the heat of the sun, when the exuding oil runs off and is collected. In a somewhat improved form this process of rendering is practised in the preparation of palm oil (*q.v.*) and the rendering of the best (Cochin) coconut oil by boiling the fresh kernels with water. Naturally these processes can only be applied to those seeds which contain large quantities of fatty matter, such as coconuts and olives. The rendering process is, however, applied on a very large scale to the production of animal fats, such as tallow (*q.v.*), lard, bone fat and whale oil (*q.v.*). The method consists essentially in cutting up the fatty matter into small fragments, which are transferred to vessels containing water, wherein the comminuted mass is heated by steam, either under atmospheric pressure in open vats or under higher pressure in digesters. The fat gradually exudes and collects on top of the water, whilst the membranous matter, "greaves," falls to the bottom. The fat is drawn off the aqueous (gluey) layer and strained through sieves or filters. The greaves are placed in hair or woollen bags and submitted to hydraulic pressure, by which a further portion of fat is obtained (cf. *Pressing*). In the case of animal fats intended for edible purposes, such as lard, suet for margarine, etc., the greatest cleanliness must, of course, be observed, and the temperature kept as low as possible in order to obtain a perfectly sweet and pure material. To obtain a harder product, fats, such as tallow, are frequently subjected to pressing to squeeze out the more liquid portions, which are sold as oleo oil, lard oil, etc.

Pressing.—The boiling out process cannot be applied to small seeds, such as linseed, rapeseed, etc. Whilst, perhaps, the most primitive method of expression was to crush the seed in mortars until the oil should exude, in the East, where vegetable oils form an important article of food and serve also for other domestic purposes, various ingenious applications of lever and of wedge presses have been used from the remotest times. A detailed description is given by Pliny of the screw presses used by the Romans for the production of olive oil. At an early stage in history the Chinese employed the same series of operations which are followed in the most advanced mills of modern times, viz., bruising and reducing the seeds to meal under edge-stones, heating the meal in open pans and pressing out the oil in a wedge press. This primitive process is still carried out in Manchuria, in the production of soya bean cake and oil, one of the staple industries of that country. The Dutch or stamper press, invented in Holland in the 17th century, was almost exclusively employed in Europe for pressing oil-seeds until the early years of the 19th century; it yielded place to the hydraulic press which has practically superseded all other appliances for expression. The sequence of operations in treating oil-seeds, oil-nuts, etc., is as follows: As an important preliminary operation the seeds, etc., are freed from dust, sand, and other impurities by sifting; in the case of seeds amongst which are found pieces of iron (hammer heads among palm-kernels, etc.), the seeds are passed over magnetic separators. The seeds and nuts are then decorticated (where requisite), the shells removed and the kernels ("meats") converted into a meal by grinding between finely grooved rollers. The comminuted mass, forming a more or less coarse meal, is either expressed in this state, or subjected to preliminary heating according to the quality of product required. For the preparation of *edible* oils, the meal is packed in bags and expressed in hydraulic presses in the cold, under a pressure of 300 atmospheres or more. The cakes remain under pressure for about seven minutes. Oil expressed in the cold dissolves the least amount of colouring matter, etc., and hence has suffered least in quality; oils so obtained are known in commerce as "cold-drawn oils," "cold pressed oils," "salad oils," "virgin oils."

By pressing in the cold only part of the oil is recovered. A further quantity is obtained by pressing the meal at a somewhat elevated temperature, either after the cold-drawn oil has been taken off, or in the case of oleaginous seeds of low value, *e.g.*, cottonseed, coconut, where it is of importance to extract as much oil as possible in one operation, immediately after the meal has left the mill. The process, which is general in application to all oil-seeds is described in some detail, with illustrations of typical hydraulic presses, in the article Coco-Nut Oil and Cake. Oil obtained from heated meal is usually more highly coloured and harsher to the taste than cold-drawn oil, more of the extractive substances being dissolved and intermixed with the oil. Such oils are hardly suitable for edible purposes and are chiefly used in manufacturing processes. According to the care exercised by the manufacturer and the range of temperature to which the seed is heated, various grades of oil are obtained. The residual meal is used as cattle-food, or if from poisonous seeds such as castor beans, as manure.

Extraction by Solvents.—The cakes obtained in the foregoing process still retain considerable proportions of oil, usually about 10%. If it be desired to obtain larger quantities than are yielded by the methods described above, the extraction of the seeds must be performed by the use of volatile solvents. Extraction by carbon disulphide was first introduced in 1843 by Jesse Fisher of Birmingham. For several years the process made little advance, for the colour of the resulting oils was dark and the taste sharp. The oil retained traces of sulphur, causing a disagreeable smell in soaps made from it, and the blackening of substances with which it was used. The meal was so tainted with carbon disulphide that it was absolutely out of the question to use it as cattle-food. With improvement in the manufacture of carbon disulphide these drawbacks have been surmounted to a large extent, and the practice of extraction with this solvent has especially gained extension for waste olive marc in France, Italy and Spain. Modern methods largely use petroleum ether (shale naphtha is more usual for the oil extraction of bone-fat); benzene and the non-inflammable hydrocarbons such as trichlorethylene, have been used, but have not proved so satisfactory, and in the latter case the risk of physiological action on the workmen, has militated against their wider utilisation. The methods of operation have been improved so that losses of solvent do not amount to more than 1%. Good quality oils can be obtained, and the processes are able to compete with expression, the choice of method resting mainly on considerations of the particular seed to be treated and the type of meal desired.

The apparatus employed on the large scale depends on the temperature at which the extraction is to be carried out. In the main two types of plant are differentiated, viz., for extraction in the cold, and for hot extraction. The seed is prepared as for pressing, but the grinding is coarser. In cold extraction the meal is placed in a series of closed vessels, and the solvent allowed to percolate by displacement (upward, in a recent process) on the "counter-current" system. The solution of extracted fat is then transferred to a steam-heated still, where the solvent is driven off and recovered by condensation to be used again. The last remnants of volatile solvent in the oil are driven off by a current of steam blown through the oil in the warm state. The hot-extraction process is carried out in apparatus, the principle of which is exemplified in the well-known Soxhlet extractor. The comminuted seed, spread on trays, is placed inside a vessel containing the solvent and fitted with a reflux condenser. On heating the solvent by means of a steam-coil or jacket the vapours rise through and around the meal, passing into the condenser, whence the solvent drops back as liquid on to the hot meal, percolating through it, and reaches the bottom of the vessel as a more or less saturated solution of oil in the solvent. The solvent is again evaporated, leaving the oil behind, the process proceeding continuously until the extraction is deemed finished. The oil solution is run into a still and the oil freed from solvent as already described. The solvent remaining in the meal is removed by a similar steaming process. It is true that on the European continent extracted meal, especially rape meal from good Indian seed and palm kernel meal, is somewhat largely used as cattle-food in admixture with press-cake; in England extracted meal is not

so employed, but finds its proper use in manuring the land.

Refining and Bleaching.—The oils and fats prepared from fresh ("sweet") material by any of the methods detailed above are practically neutral. Carefully rendered or cold-drawn oils are, as a rule, sufficiently pure to be delivered to the consumer, after a preliminary settling has allowed any mucilaginous matter, animal or vegetable fibres, etc., to separate. The clarification process may be shortened by filtering the oils, or otherwise brightening them, *e.g.*, by blowing with air. In many cases these methods still suffice for the production of commercial fats. Oils intended for use as salad oils, or as lubricants, which deposit "stearine" in the cold are "demargerinated" (*see* p. 749).

In special cases, such as the preparation of edible oils and fats, a further improvement in colour and greater purity is obtained by filtering the oils over absorbent materials such as charcoal, fuller's earth, etc. As in the case of coconut and palm-kernel oils, a preliminary purification in a current of steam may be employed. For refining oils and fats intended for edible purposes, only the foregoing methods, which may be summarized by the name of physical methods, can be used; the only chemicals permissible are alkalies or alkaline earths to remove free fatty acids. The practice of refining by caustic soda has gained considerable extension; the fatty acids are neutralised by caustic soda and removed in the form of soaps by washing, but technically, the process is complicated by the formation of emulsions. Treatment with other chemicals renders the fats unfit for consumption. Hence, all bleaching and refining processes involving other means than those enumerated can only be used for technical oils and fats. There is no universal method of oil refining applicable to any and every oil and fat. Not only must each kind of fat be considered as a special problem, but frequently even varieties of one and the same fat are apt to cause the same difficulties as would a new individual. In many cases purification by sulphuric acid is still usefully applied. The oil is treated with a small proportion of concentrated sulphuric acid; this acts on the suspended impurities, carbonising them to some extent, and causes them to coagulate in the form of a flocculent mass, which settles out carrying with it mechanically other impurities that have not been acted upon. This method is chiefly used in the refining of linseed and rape oils. After treatment with sulphuric acid or caustic soda the oils must be thoroughly washed; the water is allowed to settle out and the oils finally filtered.

A large variety of reagents are in use for bleaching technical oils intended for soaps, lubricants, paints, etc. In general, besides treatment with absorbent media, or exposure to air and light (olive oil), bleaching methods involve the use of oxidising agents such as sodium dichromate and acid, permanganate, hypochlorites, metallic per-salts, peroxides, etc.

Fat-hardening.—There is great demand in the arts for hard fats, and a great development of the fats and oils industry took place in the early years of the present century as a result of the invention of a successful method for converting the liquid unsaturated fatty acids and glycerides into the corresponding solid saturated bodies. The change ("hardening," "hydrogenation") which consists in the addition of hydrogen to the unsaturated bonds, *e.g.*,

$$\underset{\text{oleic acid}}{CH_3(CH_2)_7HC = CH(CH_2)_7COOH} + \underset{\text{hydrogen}}{H_2} = \underset{\text{stearic acid}}{CH_3(CH_2)_7CH_2CH_2(CH_2)_7COOH}$$

proved to be difficult of practical realisation. Many attempts had been made; stearolactone had been prepared by the action of concentrated sulphuric acid on oleic acid, and palmitic acid by treatment with potash, while the conversion into stearic acid itself had been effected by heating oleic acid under pressure with small quantities of iodine, or by subjecting it to the action of hydrogen under the influence of the silent electric discharge. None of these processes, however, proved economically successful on the commercial scale. The problem was solved by the application of the general reaction discovered by Sabatier and Senderens, namely, that hydrogen could be assimilated by unsaturated compounds in the presence of a metallic catalyst. The principle was found to be readily applicable, not only to fatty acids, but also to the glycerides. The metal in general use is nickel; platinum and palladium are active catalysts, and by their use the reaction can be effected at much lower temperatures, but their high cost and susceptibility to poisoning by traces of impurities preclude their commercial use.

The usual process consists in passing hydrogen through the oil, which is intimately mixed with the catalyst; this consists of finely divided metallic nickel, which, as a rule, has been deposited on an inert support, such as kieselguhr or fuller's earth. The reaction is conducted at temperatures between 140° and 200° C, according to conditions. After hydrogenation the oil has to be filtered to free it from powdered catalyst; the nickel from the latter is recovered. A recent innovation, designed to allow of continuous working, and to obviate the tedious processes of filtration and recovery of the nickel from the oil-saturated residue, employs fine nickel turnings. The turnings are placed in perforated cages in the reaction vessel. The pre-heated oil and the hydrogen flow over them on the counter-current system. The oil delivered is free from nickel and does not require filtration; when the activity of the catalyst becomes reduced, as a result of gradual poisoning, it is easily regenerated by electrolytic oxidation and subsequent reduction. The mechanism of oil-hydrogenation, and the way in which the nickel assists the reduction, has not been fully explained; it appears that the reduction takes place in stages, the most unsaturated acids being first attacked. As the hardening process is always accompanied by a certain amount of deodorisation, more especially in the case of whale and fish oils, it has rendered possible the utilisation of these oils for the manufacture of hard soap, and has led to the substitution of cheaper vegetable oils, hydrogenated to the required consistency, for the more expensive tallow and lard.

The detection of hardened fats in a mixture is a difficult, if not an insoluble, problem. Indications may be furnished by the detection of fatty acids of high molecular weight, *e.g.*, behenic acid from hardened rape or marine animal oils, or of considerable proportions of iso-oleic acid, which is a transition product in the conversion of oleic into stearic acid.

Applications.—It is almost impossible to enumerate the many applications of the fats: in the table above the principal uses of some typical oils and fats are given. Almost all the best quality fats, including hardened whale oil, etc., can be used for edible purposes (margarine, cooking fats, salad oils, etc.), and some constitute a staple article of diet for native races, for instance, palm oil in W. Africa, soya bean oil in Manchuria.

In the arts the fats are used for soap-making, candle stearine manufacture (*see* CANDLE; SOAP) and leather-dressing; the latter industry provides an outlet for fish-oils and other low grade fats. Linseed oil, tung oil, and to a less extent other drying oils, are employed as the basis of paints, varnishes and for linoleum. Many of the non-drying oils (*e.g.*, neat's foot oil, sperm oil, etc.), are employed as lubricants, either alone or compounded with mineral oils (rape, castor oil), while lubricating greases are made from metallic soaps. Rape oil (colza) and other oils are still used as burning oils in remoter districts. Castor, and "tournant" olive oils provide the turkey-red oils used in dyeing textiles (*see* also GLYCERINE).

In medicine.—Some of the oils possess peculiar properties for which they are valued medicinally. Castor (*q.v.*) and curcas oils have a strong purgative action, while chaulmoogra oil, and others of the same group, have recently attracted attention as specifics for leprosy. Lard, olive, almond and other oils find application in pharmacy as vehicles for various medicaments (*see* also COD LIVER OIL).

Commerce.—In the table the principal countries of origin of the sources (seeds, etc.) of the fats are given. In a great many cases the oils are not extracted in their country of origin; the raw materials are shipped to European countries and America; thus Marseilles becomes the centre of the coconut oil trade, Liverpool and Hull centres of oil-seed expression, etc. Recent

development of industry in tropical countries, together with the war-time need for economy in freightage, has led, however, to increased production of oils and fats in the native countries; thus we find exports of copra from the Philippines decreasing, while the exports of oil increase. Statistics for the production of fats are very scanty; estimations based on available import and export returns take no account of the consumption in the countries of origin, which may be considerable, *e.g.*, coco-nut oil in the Philippines, palm oil in W. Africa. For the available data, the reader is referred to the trade returns (U.K., U.S.A., etc.) and to the publications of the International Institute of Agriculture, Rome—*Oleaginous Products and Vegetable Oils* and the *Year Book of Agricultural Statistics.*

Production.—The production of oils is liable to considerable fluctuation, but the following estimates may be taken as representative. On the whole the production and consumption of oils and fats has steadily augmented since World War I, the increase being especially marked in the case of soya-bean, coco-nut, palm-kernel and groundnut (peanut) oils.

TABLE II.

Production of Oil-seeds, Nuts, etc. (reduced to Oil-equivalent), and Oils

Oil	1924*	1926†	1937‡
	1,000 quintals	Tons	Tons
Cottonseed	19,260	931,963	1,044,000
Copra	13,000	733,431	940,450
Groundnut (peanut)	12,366	527,441	1,010,000
Linseed	10,000	694,292	750,000
Olive	7,653	626,000	800,000
Rapeseed	4,652	73,786	280,000
Soya	4,000	398,961	618,000
Sunflower	..	136,730	375,000
Palm and palmkernel	..	408,891	561,000
Other vegetable oils	..	..	228,000
Lard	..	..	400,000
Tallow	..	..	320,000
	Barrels	Barrels	Tons
Whale oil production	641,583	1,166,857	400,000

WAXES

The *waxes* consist chiefly of the fatty acid esters of the higher monohydric alcohols, with which are frequently associated free alcohols as also free fatty acids. Important among the acids found are palmitic acid, occurring in beeswax and spermaceti (*q.v.*), cerotic acid, $C_{25}H_{51}COOH$, in beeswax, wool-wax and other waxes, and melissic acid, $C_{29}H_{59}COOH$, of beeswax.

The hydroxylated lanopalmic, $C_{15}H_{30}(OH)COOH$, and lanoceric, $C_{29}H_{57}(OH)_2COOH$, acids also occur in wool-wax. The alcohols cetyl alcohol, $C_{16}H_{33}(OH)$ ("ethal" of the older writers) of spermaceti, and myricyl (melissyl) alcohol, $C_{30}H_{61}(OH)$, of beeswax and carnaüba wax are the most important, while the cyclic sterols, cholesterol and isocholesterol, occur in considerable amounts in wool-wax.

Spermaceti consists practically of cetyl palmitate, Chinese wax of ceryl palmitate. The other waxes, especially wool-wax, are of more complex composition.

The waxes can be simply classified, similarly to the fats, as follows:—

I. Liquid waxes
II. Solid waxes
  A. Vegetable waxes
  B. Animal waxes.

The table enumerates the most important waxes (*see* also separate articles, SPERMACETI, etc.).

The occurrence and physiological importance of the waxes have been discussed above. In their physical properties the natural waxes resemble the fats. They behave similarly towards solvents, and in the liquid condition leave a grease-spot on paper.

TABLE III.

Wax	Occurrence	Iodine value	Principal use
Liquid waxes			
Sperm oil	Atlantic, Pacific	81–90	Lubricant
Arctic sperm oil	Arctic	67–82	"
Solid waxes			
Vegetable waxes:			
Carnaüba wax	Brazil	13	Polishes, phonograph mass
Sugar cane wax	..	60	Polishes
Montan wax (distilled from peat)	Germany, Ireland, etc.	12–16	" phonograph mass
Animal waxes:			
Wool-wax	As mutton-tallow	30–35 (Wijs)	Ointment ("lanolin")
Beeswax	General	8	Candles, polishes
Spermaceti	As sperm oil	0–4	Candles, surgery
Insect wax, Chinese wax	China	0–1.4	Candles, polishes, sizes

An important property is easy formation of emulsions with water, of which large quantities can be incorporated (lanolin [*q.v.*]).

Only a few vegetable waxes are found in sufficiently large quantities to be of commercial importance; so far carnaüba and sugar-cane waxes are practically the only plant waxes of importance in the world's markets. The most important animal wax is beeswax (*q.v.*), collected in almost all parts of the world. An exceptional position is occupied by wool-wax, the main constituent of the natural wool fat that covers the hair of sheep, which is obtained as a by-product in scouring raw wool. Wool-fat is purified on a large scale and brought into commerce, under the name *lanolin*, as an ointment, which is valued for its property of easy assimilation by the skin.

OIRAT (OR OIROT) AUTONOMOUS AREA, an autonomous administrative division of the Russian S.F.S.R., created in 1922, within the Siberian area, bounded by Kazakstan on the southwest and Mongolia, with the Mongolian Tannu Tuva republic on the south and east, and by the Siberian area on the north. Area 35,934 sq.mi. Pop. (1939) 161,431. It lies between 49° 5′ and 52° 4′ N. and 84° and 89° 55′ E., and is entirely rural. The administrative centre Oirat Tura is on Katun river. The area is mountainous, lying in the Altai region of West Siberia, which forms part of the Alpine highlands bordering the Mongolian plateau. Within it lies Mount Byelukha, whose summits rise to 14,890 ft. and 14,560 ft. respectively, and on which several glaciers exist. Numerous spurs strike from the Sailughem mountains toward the Siberian plain in all directions, among which are the Chuya Alps, average altitude 9,000 ft., with peaks rising to 12,000 ft., and at least 10 glaciers on the northern slope, and the snow-clad Katun Alps (10,000 ft.).

The Katun river rises in a glacier in a wild gorge on the southwest slope of Byelukha and, after making a wide curve, pierces the Katun range and flows to the north. The upper course of the Biya, which with the Katun later forms the Ob, lies in the Oirat area. The Biya flows from the beautiful alpine Lake Teletskoye, to the south of which are the high Bashkaus, Chulyshman and Chulcha valleys all draining into the lake. The Kok-su and the Argut are the chief among the numerous tributaries of

the Katun.

The climate is severe, average winter temperature $-13°$ to $-16°$ C, summer 16° to 18° C. The maximum rainfall is in the Chernevoi district of the northeast, on the right bank of the Katun river, thickly forested with Siberian cedar and fir. In the northwest the conifers are mixed with birch, poplar and aspen. The Chuya, Kurai and Chulyshman Alps lie above the tree limit and have much tundra. The soils are mainly bog, meadow, rubble and forest clays; their poor character, the short vegetation period and the drought of the region under the influence of winds from Mongolia make cultivation difficult. Wheat and oats, with a little barley, rye, millet, flax, hemp, buckwheat and potato are grown, but only a small part of the area is under cultivation.

Primitive irrigation channels had rendered crop production possible especially in the Uimonsk district in the bend of the Katun river. Besides many of the natives depend on transport in connection with the trade between Kobdo in Mongolia and Biisk in Siberia for supplementary income.

Forest fires and reckless exploitation for army purposes diminished the timber in accessible places and also reduced the number of fur-bearing animals, already diminishing in pre-war times through intensive hunting. Squirrel, bear, fox, ermine and sable are the chief fur-bearing animals of the region. The collection of cedar nuts for the oil pressing factories of Siberia, formerly an important occupation, was also affected by the causes given above. Timber, in any case, is difficult to exploit in the absence of transport facilities in a wild and rocky country. The chief occupation of the people is stock raising, horses, working and dairy cattle, sheep, goats and pigs being bred. War conditions, followed by a period when troops of bandits infested the region, not only destroyed many of the best breeds, but caused the herdsmen to cross into Mongolia, with their remaining cattle and flocks.

Epizootic diseases are prevalent, possibly because of their spread along the road from Mongolia. Milk and meat, with fermented mare's milk (kumiss) form the staple diet of the people. Raw leather with butter from the farms of the Russian settlers, are exported to a small extent. Meat and wool are used locally, for peasant industries have to supply local needs of homespun, felt, wooden and leather articles and flour and cheese. There is no factory industry.

Beekeeping is profitable among the Russian settlers, and is increasing. The maral deer, from whose horns a substance called *panty,* used as a medicine in China, is obtained, is kept by the natives.

Of the population about 50% are Russians, partly descendants of the Old Believers who took refuge here from religious persecution from 1761 onwards. Colonization began in the 19th century, the settlers being mainly peasants from the crown lands, but no attempt was made to organize Russian colonization until 1874–1879. The colonists have occupied the areas suitable for cultivation, especially the Uimonsk region. Disputes between the Russian tillers of the soil and the nomad herdsmen of the hills were frequent and sharp before the creation of the autonomous area. The etymology of the word Oirat or Uirad is uncertain. Remusat and Pallas considered the term Durben Uirad, by which name Chinese writers speak of the Kalmucks, to mean The Four Allies, referring to the confederacy of four Kalmuck tribes which existed in the middle ages. Schmidt states that the Volga Kalmucks call themselves Uirad or Mongol Uirad, and the term Uirad Buriat also occurs in the records. Howorth after at first inclining to the view of Pallas and Remusat and considering that the term had no racial significance, later decided that Uirad was an indigenous term among the Kalmucks. Marco Polo says that Jenghiz Khan allowed the Horiads, out of gratitude for a victory they had won for him, to share the milk of his private herd of white mares, and Yule identifies the Horiads with the Uirads. According to Vambéry the term means grey mare.

The Uirads are recorded as living in the region of the "eight rivers," *i.e.,* the sources of the Kem or Upper Yenisei, at the accession of Jenghiz Khan. Apparently they were Mongols with a Turkish admixture. They submitted to Jenghiz Khan without any struggle and their chieftain Kara Kiragho was one of the nine famous generals or *orloks* who commanded divisions of Jenghiz Khan's army. A long struggle afterwards ensued between the Uirads and the Mongols, and in the 15th century the greater part of the western Mongols were under Uirad overlordship. Towards the end of the 16th century the Uirad power decayed and the Mongols recovered their supremacy. The Dzungarians later overran the Uirad territory, but were themselves conquered by the Chinese in the 18th century, when many took refuge with the Kirghiz in Russian territory. The non-Russian population of the Oirat autonomous area is thus composed of the descendants of these various Turkish, Kalmuck and Mongol tribes and includes also some Kirghiz shepherds. These Altai hill tribes are all nomad herdsmen, supplementing their income by hunting and by undertaking transport along the road from Kobdo to Biisk which passes through the Oirat area. It should be noted that the Telengets of the district north of Kusnetsk, lying outside the Oirat area, call themselves Oirat and that their language and poetry is similar to that of the Altaians, Howorth suggests that they may have been closely allied. Another division of the Uirads in 1296 deserted the Khan of Persia and went to Damascus. Among Altai mountain peoples are the Mountain or Black Forest Tatars, living in the cedar forest region between the Katun and Lake Teletskoye and supplementing their semi-nomad herding by collecting cedar nuts and roots and hoeing the soil in a primitive way for wheat and barley cultivation. The Kumandins live on both banks of the Biya from the mouth of the Lebed downwards, and are taking to settled agriculture. Another Tatar group lives along the Lebed shores and is mainly occupied in hunting.

See Henry Howorth, *The History of the Mongols* (1876), and in Russian *Atlas of the U.S.S.R.* (1928).

OISE, a department of northern France, three-fourths of which belonged to Île-de-France and the rest to Picardy, bounded north by Somme, east by Aisne, south by Seine-et-Marne and Seine-et-Oise, and west by Eure and Seine-Inférieure. Pop. (1936) 402,569; area 2,273 sq.mi. As its name implies, the department includes a good deal of the lower basin of the Oise and its tributaries, forming a broad basin dissected from the outlying zone of the Eocene deposits. To the south-east of the Oise the Eocene forms a plateau with a considerable amount of forest, especially towards the north. To the north-west of the Oise the Eocene is capped along various south-east–north-west ridges by Pliocene, forming the hills of the Pays de Bray (770 ft.). The valley of the Oise itself is a sunny region, with less than 24 in. of rain per annum, and a range of seasonal averages of temperature from about 38° to 64° F.

Clay for bricks and earthenware, sand and building-stone are among the mineral products of Oise, and peat is also worked. Pierrefonds, Gouvieux, Chantilly and Fontaine Bonneleau have mineral springs. Wheat, oats and other cereals, potatoes and sugar beet are the chief agricultural crops. Cattle are reared especially in the western districts, where dairying is actively carried on. Bee-keeping is general. Racing stables are numerous in the neighbourhood of Chantilly and Compiègne. The chief industries of the department are manufactures of sugar and alcohol from beetroot. The manufacture of furniture, brushes (Beauvais) and other wooden goods and of toys, fancy-ware, buttons, fans and other articles in wood, ivory, bone or mother-of-pearl are important. There are also woollen and cotton mills, and manufactories of woollen fabrics, blankets, carpets (Beauvais), hosiery and lace (Chantilly and its vicinity). Creil and the neighbouring Montataire form an important metallurgical centre. Oise is served by the Northern railway, on which Creil is an important junction, and the Oise and its lateral canal and the Aisne afford about 70 m. of navigable waterway.

There are three arrondissements—Beauvais, Compiègne and Senlis—with 35 cantons and 701 communes. The department forms the diocese of Beauvais (province of Reims) and part of the region of the II army corps and of the *académie* (educational division) of Paris. Its court of appeal is at Amiens.

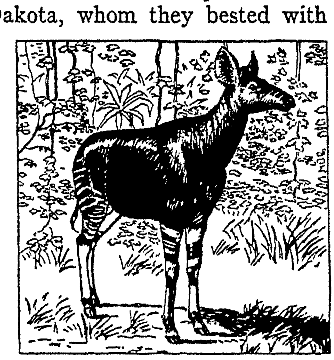
OISE, a river of northern France, 187 mi. long, flowing south-

west from the Belgian frontier to join the Seine 39 miles below Paris. It drains the north-eastern part of the Paris basin. Rising in Belgium, 5 m. S.E. of Chimay at a height of 980 ft., the river enters France after a course of little more than 9 m. It divides below Guise into several arms and is joined by the Serre (left), near La Fère. Thence as far as the Ailette (left), it flows through well-wooded country to Compiègne, above which it receives the Aisne (left). Skirting the forests of Compiègne, Halatte and Chantilly (all left), and receiving near Creil the Thérain and the Brèche (both right), the river flows past Pontoise to reach the Seine. Its channel is canalized (depth 6 ft. 6 in.) from Janville to its mouth. Above Janville a lateral canal continued by the Sambre-Oise canal accompanies the river to Landrecies. It is connected by canal with the canal system of Flanders and with the Somme and the Eastern canal systems. (*See* SEINE.)

OISIN (pronounced *Usheen*), reputed to be the son of Finn mac Cumhaill (*q.v.*), a heroic warrior and bard. He figures to but a small extent in the earlier literature of the Finn cycle, being eclipsed by his father and by his son Oscar. But in the later "Ossianic" literature he is prominent as the narrator of the events through which he claims to have lived. According to the legend, he remained alive after the Battle of Gabhra (Garristown, Co. Dublin) in which Cairbre Liffechair, son of Cormac mac Airt, destroyed Finn and his followers (A.D. 283), and survived long enough to meet St. Patrick (who arrived in Ireland in A.D. 432) and to tell him the ancient traditions of his youth. This prolonged existence was accounted for by his having been carried off by a fairy maiden to the Happy Otherworld; a tale not found in any ancient manuscript, but preserved orally, and successfully versified by the 18th-century Irish poet Michael Comyn. In a very valuable prose tract, *Agallamh na Senórach* ("The Colloquy of the Elders"), Patrick is described as making a circuit of Ireland, with Oisin and his old companion in arms, Caeilte, as *ciceroni.* The same formula was afterwards adopted in verse, but with the difference that whereas in the prose narrative the pagan warriors and the saint treat each other with courtesy, in the verses they argue with a petulance often descending to ribaldry on both sides. The poet's name, in the form "Ossian," was popularized by James Macpherson; but his version of the tales and poems is so much manipulated as to be practically a new work.

Agallamh na Senórach is published with a translation in O'Grady's *Silva Gadelica* (1890). For the chief Ossianic poems *see* the publications of the Ossianic Society (1856, 1858); also Eoin MacNeill, *Duanaire Finn* (Irish Texts Society, 1908). *See* also L. C. Stern, *Die Ossianischen Heldenlieder* (English Translation in *Transactions of the Gaelic Society of Inverness,* xxii., p. 257). (R. A. S. M.)

OJIBWA. The Ojibwa or Chippewa form a large, loosely knit group of Algonkin Indians, said to have held originally the northern shores of lakes Huron and Superior, but extending in the historic period also westward across northern Minnesota and into Manitoba as far as Turtle mountain. Their expansion was largely at the expense of the Dakota, whom they bested with firearms obtained from the French. They were friendly to the French, and later to the British against the Americans, but have never been aggressive in warfare, at least not unitedly so, although esteemed brave. They were a timber people, farming only in part, and subsisting largely on game and wild rice. They are a large and widely spread group, numbering 30,000 or more, about equally divided between Canadian and American soil. (A. L. K.)



BY COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY

MALE OKAPI (OKAPIA JOHNSTONI), FOUND MOSTLY IN THE CONGO DISTRICTS

OKAPI (ō-kah'pĭ), large animal allied to giraffes, inhabiting the Semliki forest between Lakes Albert and Albert Edward in Central Africa. First obtained by Sir H. H. Johnston, in 1900, the okapi (*Okapia johnstoni*) has shorter legs and neck than the giraffe, standing 5 ft. at the shoulder. In colour it is purplish, with the sides of the face puce and the limbs barred with black and white. The horns, only present in the males, are capped with a small polished tip which alone penetrates the covering skin. The skull is intermediate between that of the giraffe and that of the extinct *Samotherium* of the Lower Pliocene of Europe. The okapi dwells in the densest parts of the primeval forest, feeding on leaves of trees, shrubs and epiphytes. Its colouring renders it practically invisible at a short distance. It belongs to the family Giraffidae (*see* PECORA).

See for further details Ray Lankester, *Trans. Zool. Soc. of London* (xvi., 6, 1902).

OKEGHEM, JOANNES (also OCKEGHEM, OCKENHEIM, OKERGAN, JEAN DE) (early 15th cent.–*c.* 1495), was born early in the 15th century at Termonde, East Flanders. He was a chorister at Antwerp in 1443 and is generally supposed to have been a pupil of Binchois. The latter part of his life was spent at Tours, where he held the coveted post of treasurer to St. Martin's church under Louis XI. He stands out in the early history of music as one of the greatest of teachers and is by common consent regarded as the founder of the second Netherlands school of contrapuntists, covering the latter half of the 15th century. Josquin des Près and De la Rue were but two among the many famous pupils who carried his teaching into all countries. His skill and ingenuity in counterpoint were considered extraordinary even in that age of elaboration. He wrote, among others, a transposing mass, the *Missa cujusvis toni,* which could be sung in any of the church modes, and a complicated motet for 36 voices. In fugue he introduced the *stretto,* a now familiar device by which the answer follows the subject at a closer interval than in the original statement, and in addition to the usual form of canon in unison he added the canon at the fourth below. Much of his work was destroyed in the wars, or lost, and he lived too early to see his works in print. The masses and motets were not published till after his death. Two masses (Trent codices) have been published by the *Gesellschaft sur Herausgabe von Denkmälern der Tonkunst in Osterreich* (Vienna) and 4 Chansons are in A. W. Ambros, *Geschichte der Musik* (5 vols., Leipzig, 1862–82. The 5th vol. containing examples of music, has not been re-issued).

See also A. de Marsy, *Un musicien flamand: Jean de Ockeghem* (1895); Dragan Plauenocz, *J. Ockeghem als Motett- und Chansons-Komponist* (Vienna, 1925).

OKEN, LORENZ (1779–1851), German naturalist, whose real name was Ockenfuss, was born at Bohlsbach, Baden, on Aug. 1, 1779. He studied at Würzburg and Göttingen, where he became *Privatdozent.* In 1807 he was appointed professor extraordinarius of medical sciences at Jena. His inaugural discourse on the signification of the bones of the skull, based upon a discovery he had made in the previous year, was delivered in the presence of Goethe, as privy-councillor and rector of the university, and was published in the same year, with the title, *Ueber die Bedeutung der Schädelkrochen.* In 1816 he began to publish at Weimar the periodical *Isis, eine encyclopädische Zeitschrift, vorzüglich für Naturgeschichte, vergleichende Anatomie und Physiologie.* Comments on the politics of other German States led to a remonstrance from the court of Weimar, which demanded either the suppression of the *Isis* or resignation. Oken resigned, and continued to publish the *Isis* at Rudolstadt until 1848.

In 1821 Oken promulgated the idea of annual general meetings of German naturalists and medical practitioners, the first meeting being held in Leipzig in 1822. The British Association for the Advancement of Science was first organized after the Okenian model.

In 1828 Oken resumed his duties as privat-docent in the newly-established University of Munich, and soon afterwards was appointed professor in the same university. In 1832, on the proposal by the Bavarian Government to transfer him to a professorship in a provincial university of the State, he resigned his appointments and left the kingdom. He was appointed in 1833 to the professorship of natural history in the then recently-established University of Zurich, where he resided until his death, on Aug. 11, 1851.

All Oken's writings are eminently deductive illustrations of a foregone and assumed principle, which, with other philosophers

of the transcendental school, he deemed equal to the explanation of all the mysteries of nature. According to him, the head was a repetition of the trunk—a kind of second trunk, with its limbs and other appendages; this sum of his observations and comparisons—few of which he ever gave in detail—ought always to be borne in mind in comparing the share taken by Oken in homological anatomy with the progress made by other cultivators of that philosophical branch of the science. Oken's axiom that "all the parts of higher animals are made up of an aggregate of infusoria or animated globular nomads" is of the same order as his proposition that the head is a repetition of the trunk. This latter proposition was claimed to have been discovered by Goethe. He stated this in his *Morphologie* in 1820. A controversy followed; Oken replied with an able statement in *Isis* (Part 7, 1847).

The following is a list of Oken's principal works: *Grundriss der Naturphilosophie, der Theorie der Sinne; und der darauf gegründeten Classification der Thiere* (1802); *Die Zeugung* (1805); *Abriss der Biologie* (1805); *Beiträge zur vergleichenden-Zoologie, Anatomie und Physiologie* (along with Kieser, 1806–07); *Ueber die Bedeutung der Schädelknochen* (1807); *Ueber das Universum als Fortsetzung des Sinnensystems* (1808); *Erste Ideen zur Theorie des Lichts, der Finsterniss, der Farben und der Wärme* (1808); *Grundzeichnung des natürlichen Systems der Erze* (1809); *Ueber den Werth der Naturgeschichte* (1809); *Lehrbuch der Naturphilosophie* (1809–11; 2nd ed., 1831; 3rd ed., 1843; Eng. trans., *Elements of Physiophilosophy*, 1847); *Lehrbuch der Naturgeschichte* (1813, 1815, 1825); *Handbuch der Naturgeschichte zum Gebrauch bei Vorlesungen* (1816–20); *Naturgeschichte für Schulen* (1821); *Esquisse d'un Système d'Anatomie, de Physiologie, et d'Histoire Naturelle* (1812); *Allgemeine Naturgeschichte* (1833–42, 14 vols.).

OKHOTSK, SEA OF, a part of the western Pacific Ocean, lying between the peninsula of Kamchatka, the Kurile Islands, the Japanese island of Yezo, the island of Sakhalin, and the Amur province of East Siberia. The Sakhalin Gulf and Gulf of Tartary connect it with the Japanese Sea on the west of the island of Sakhalin, and on the south of this island is the La Pérouse Strait.

OKI, a group of islands belonging to Japan, lying due north of the prefecture of Shimane, of which they form a part, 36° N. and 133° E. The group consists of one large island called Dogo, and three smaller isles—Chiburi-shima, Nishi-no-shima, and Naka-noshima—which are collectively known as Dozen. These four islands have a coast line of 182 mi., an area of 130 sq.mi., and a pop. (1940) of 31,794. The island of Dogo has two high peaks, Daimanji-mine (1,992 ft.) and Omine-yama (2,185 ft.). The chief town is Saigo in Dogo, distant about 40 mi. from the port of Sakai in Shimane. The name Oki-no-shima signifies "islands in the offing," and the place is celebrated in Japanese history not only because the possession of the islands was much disputed in feudal days, but also because a former emperor and an emperor were banished thither by the Hojo regents in the 13th century.

OKLAHOMA is a west south central state of the United States of America, lying between approximately 33° 38′ and 37° N and 94° 26′ and 103° W. It is bounded north by Colorado and Kansas; east by Missouri and Arkansas; south by Texas, from which it is separated in part by the Red river; and west by Texas and New Mexico. It has a total area of 69,919 sq.mi., of which 888 sq.mi. are water surface. Although the extreme western limit of the state is the 103rd meridian, the only portion west of the 100th meridian is a strip of land about 35 mi. wide in the present Beaver, Texas and Cimarron counties, and formerly designated as "No Man's Land." Oklahoma is called the "Sooner state" because those who entered on April 22, 1889, with the rush, found some of the best land taken up by those who had evaded the guards and entered the territory in advance of the official opening. These persons who evaded the regulations and thus secured the best land were known as "Sooners."

Physical Features.—The topographical features of the State exhibit considerable diversity, ranging from wide treeless plains in the west to rugged and heavily wooded mountains in the east. Elevations above the sea range from 4,800 ft. (Black Mesa) in the extreme north-west to 300 ft. in McCurtain county in the south-east. The State has a mean elevation of 1,300 ft., with 34,930 sq.mi. below 1,000 ft.; 25,400 sq.mi. between 1,000 and 2,000 ft.; 6,500 sq.mi. between 2,000 and 3,000 ft.; and 3,600 sq.mi. between 3,000 and 5,000 ft.

The western portion of the Ozark mountains enters Oklahoma near the centre of the eastern boundary, and extends west-southwest half way across the State in a chain of hills gradually decreasing in height. In the south central part of the State is an elevated table-land known as the Arbuckle mountains. In its western portion this table-land attains an elevation of about 1,350 ft. above the sea and lies about 400 ft. above the bordering plains. At its eastern termination, where it merges with the plains, it has an elevation of about 750 feet. Sixty miles north-west of this plateau lie the Wichita mountains, a straggling range of rugged peaks rising about 1,500 ft. above the plain, but on account of their steep and rugged slopes they are difficult to ascend. A third group of hills, the Chautauqua mountains, lie in the west in Blaine and Canadian counties, their main axis being almost parallel with the North Fork. The north-western part of Oklahoma is a lofty table-land forming part of the Great Plains region east of the Rocky mountains.

The prairies north of the Arkansas and west of the Neosho rivers are deeply carved by small streams, and in the western portion of this area, where the formation consists of alternating shales and sandstones, the easily eroded rocks have been carved into canyons, buttes and mesas. South of the Arkansas river these ledges of sandstone continue as far as Okmulgee, but the evidences of erosion are less noticeable. East of the Neosho river the prairies merge into a hilly woodland. In the north-west four salt plains form a striking physical feature. Of these, the most noted is the Big Salt plain of the Cimarron river, in Woodward county, which varies in width from ½ mi. to 2 mi. and extends along the river for 8 miles. The plain is almost perfectly level.

Following the slope of the land, the important streams flow from north-west to south-east. The Arkansas river enters the State from the north near the 97th meridian, and after following a general south-easterly course, leaves it near the centre of the eastern boundary. Its tributaries from the north and east—the Verdigris, Grand or Neosho and Illinois—are small but important; and from the south and west it receives the waters of much longer streams—the Salt Fork, Cimarron and the Canadian, with its numerous tributaries. The extreme southern portion of the State is drained by the Red river, which forms the greater part of the southern boundary, and by its tributaries, the North Fork, the Washita and the Kiamichi.

Climate and Soils.—The climate of the State is of a continental type, with light rainfall. The western and central portions of the State are in general cooler and drier than the east. Thus, at Beaver, in the extreme north-west, the mean annual temperature is 57° F. and the mean annual rainfall 18.9 in.; while at Lehigh, in the south-east, these figures are respectively 62° and 35.1 inches. At Oklahoma City, in the centre of the State, the mean annual temperature is 59.4°; the mean for the summer (June, July and August) is 78.8°, with an extreme recorded of 108°; the mean for the winter (December, January and February) is 38.4°, with an extreme recorded of −17°. At Mangum, in the south-west, the mean annual temperature is 61°; the mean for the summer is 81° and for the winter 41°, while the highest and lowest temperatures ever recorded are respectively 114° and −17°. The mean annual precipitation for the State is 31.7 in.; the variation between the east and the west being about 12 inches.

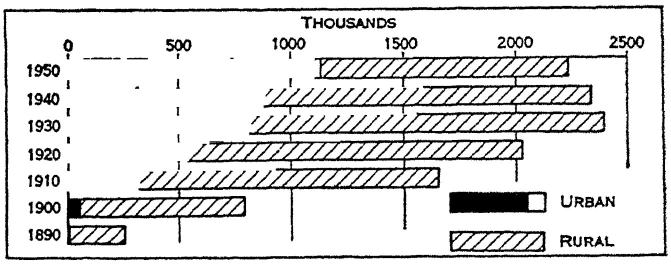
The prevailing type of soil is a deep dark red loam, sometimes (especially in the east central part of the State) made up of a decomposed sandstone, or (in the north-central part) of shales and decomposed limestone. Not infrequently there are a belt of red sandy loam on uplands north of a river, a rich deposit of black alluvium on valley bottom lands, a belt of red clay loam on uplands south of a river, and a deposit of wind-blown loess on the water parting.

History.—With the exception of the narrow strip north of the most northern section of Texas the territory comprising the present state of Oklahoma was set apart by congress in 1834, under the name of Indian territory, for the possession of the five southern tribes (Cherokees, Creeks, Seminoles, Choctaws and Chickasaws) and the Quapaw agency. Early in 1809 some Cherokees in the southeastern states made known to Pres. Thomas Jefferson their desire to remove to hunting grounds west of the Mississippi, and at first they were allowed to occupy lands in what is now Arkansas, but by a new arrangement first entered into in 1828 they received instead, in 1838, a patent for a wide strip extending along the entire northern border of Indian territory with the exception of the small section in the northeastern corner which was reserved to the Quapaw agency. By treaties negotiated in 1820, 1825, 1830 and 1842, the Choctaws received for themselves and the Chickasaws a patent for all that portion of the territory which lies south of the Canadian and Arkansas rivers, and by treaties negotiated in 1824, 1833 and 1851 the Creeks received for themselves and the Seminoles a patent for the remaining or middle portion. Many of the Indians of these tribes brought slaves with them from the southern states and during the Civil War some supported the Confederacy, but when that war was over the federal government demanded not only the liberation of the slaves but new treaties, partly on the ground that the tribal lands must be divided with the freedmen. By these treaties, negotiated in 1866, the Cherokees gave the United States permission to settle other Indians on what was approximately the western half of their domain; the Seminoles, to whom the Creeks in 1855 had granted as their portion the strip between the Canadian river and its north fork, ceded all of theirs, and the Creeks, Choctaws and Chickasaws ceded the western half of theirs back to the United States for occupancy by freedmen or other Indians. In the eastern portion of the lands thus placed at its disposal by the Cherokees and the Creeks, the federal government within the next 17 years made a number of small grants as follows: to the Seminoles in 1866, to the Sacs and Foxes in 1867, to the Osages, Kansas, Pottawatomies, absentee Shawnees and Wichitas in 1871–72, to the Pawnees in 1876, to the Poncas and Nez Percés in 1878, to the Otoes and Missouris in 1881 and to the Iowas and Kickapoos in 1883; in the southwestern quarter of the territory, also, the Kiowas, Comanches and Apaches were located in 1867 and the Cheyennes and Arapahoes in 1869. There still remained unassigned the greater part of the Cherokee outlet besides a tract embracing 1,887,800 ac. of choice land in the centre of the territory, and the agitation for the opening of this to settlement by white people increased until in 1889 a complete title to the central tract was purchased from the Creeks and Seminoles. Soon after the purchase Pres. Benjamin Harrison issued a proclamation announcing that this land would be opened to homestead settlement at 12 o'clock noon, on April 22, 1889. At that hour, no less than 20,000 people were on the border; and when the signal was given, there ensued a remarkably spectacular race for homes. In the next year that portion of Indian territory which lay south of the Cherokee outlet, and west of the lands occupied by the five tribes, together with the narrow strip north of Texas which had been denied to that state in 1850, was organized as the territory of Oklahoma.

In the meantime negotiations were begun for acquiring a clear title to the unoccupied portion of the Cherokee outlet for individual allotments to the members of the several small tribes who had received tribal allotments since 1866, and for the purchase of what remained after such individual allotments had been made. As these negotiations were successful most of the land between the tract first opened and that of the Creeks was opened to settlement in 1891, a large tract to the west of the centre was opened in 1892, a tract south of the Canadian river and west of the Chickasaws was opened in 1901 and by 1904 the entire territory had been opened to settlement with the exception of a tract in the northeast which was occupied by the Osages, Kaws, Poncas and Otoes. By the treaties with the five southern tribes they were to be permitted to make their own laws so long as they preserved their tribal relations, but since the Civil War many whites had mingled with these Indians, gained control for their own selfish ends of such government as there was and made the country a refuge for fugitives from justice. Consequently, in 1893, congress appointed the Dawes commission to induce the tribes to consent to individual allotments as well as to a government administered from Washington, and in 1898 the Curtis act was passed for making such allotments and for the establishment of a territorial government. When the allotments were nearly all made congress in 1906 authorized Oklahoma and Indian territories to qualify for admission to the union as one state. As both territories approved, a constitutional convention (composed of 100 Democrats and 12 Republicans) met at Guthrie on Nov. 20, 1906. The constitution framed by this body was approved by the electorate on Sept. 17, 1907, and the state was admitted to the union on Nov. 16.

In politics Oklahoma remained rather consistently Democratic, but with a strong Republican minority. In presidential elections through 1948 Democratic electors had been chosen nine times and Republican twice; Warren G. Harding carried the state in 1920 and Herbert Hoover in 1928. In the 16 elections for United States senators from statehood through 1950, Democrats had been successful in 13 contests, including that of 1950, and the Republican candidates in three. Democrats usually won in elections for members of the national house of representatives. The 12 men elected to the governorship through 1950 had all been elected on the Democratic ticket. The state senate had never been controlled by Republicans, and the state house of representatives had had a Republican majority only once—in 1920, the year of the Harding landslide.

Population.—The population of Oklahoma in 1890 was 258,657; in 1910 it was 1,657,155; in 1940, 2,336,434; and in 1950, 2,233,351, or 4.4% less than in 1940. The population per square mile in 1950 was 32.4 as compared with 50.7 for the U.S. as a whole.



BY COURTESY OF THE U.S BUREAU OF THE CENSUS

URBAN AND RURAL POPULATION OF OKLAHOMA: 1890 TO 1950

The narrow white space at the end of the black section of the 1950 bar represents the population of the small additional areas counted as urban under the new 1950 definition.

Of the 1950 population, 1,107,252 or 49.6%, lived in incorporated places of 2,500 or more, as compared with 37.6% in 1940, when these places constituted the urban area. The entire urban population, under a new definition set up for 1950, which included also the thickly settled suburban area, or "urban fringe," adjacent to Oklahoma City and Tulsa, and one unincorporated place of 2,500 or more outside this fringe, amounted to 1,139,481, or 51.0% of the state total.

TABLE I.—*Population of Oklahoma and Its Principal Cities*

Area	Population			Per cent of increase	
	1950	1940	1930	1940–50	1930–40
The state	2,233,351	2,336,434	2,396,040	—4.4	—2.5
Urban	1,139,481*	879,663	821,681	29.5	7.1
Rural	1,003,870*	1,456,771	1,574,359	—24.9	—7.5
Per cent urban	51.0	37.6	34 3	..	..
Principal cities					
Oklahoma City	243,504	204,424	185,389	19.1	10.3
Tulsa	182,740	142,157	141,258	28.5	0.6
Muskogee	37,289	32,332	32,026	15 3	1.0
Enid	36,017	28,081	26,399	28.3	6.4
Lawton	34,757	18,055	12,121	92.5	49.0

*Final figures for 1950 based on new definition. *See* comment in text.

The number of households in 1950 was 663,262, as compared

with 610,481 in 1940. The average population per household had declined from 3.8 in 1940 to 3.4 in 1950.

The population of the state was distributed by colour and nativity in 1950 as follows: 90.2% native white; 0.8% foreign-born white; 6.5% Negro; and 2.5% of other races, mainly Indians.

There were 100.2 males per 100 females in the native white population, and 93.8 in the Negro population; 8.7% of the population was 65 years old or over; and 48.8% of the population 14 years old and over was in the labour force.

Of the total number of employed males, 25.6% was engaged in agriculture, 6.4% in mining and oil production, 10.1% in construction, 11.0% in manufacturing and 22.4% in transportation and trade.

Government.—The constitution was adopted in Sept. 1907, two months before the state was admitted into the union. Amendments may be submitted through a majority of the members elected to both houses of the legislature or through a petition signed by 15% of the electorate, and a proposed amendment becomes a part of the constitution if the majority of the votes cast at a popular election are in favour of it. The right of suffrage is conferred on all citizens of the United States, 21 years of age or over, who have resided in the state for one year, in the county six months and in the precinct for the 30 days preceding the election. General elections are held in even-numbered years; party candidates for state, district, county and municipal offices, and U.S. senators and congressmen are chosen at primary elections.

The executive authority of the state is divided among 12 elected officials, including the governor, lieutenant governor, secretary of state, treasurer, auditor, attorney general, superintendent of public instruction, examiner and inspector, commissioner of labour, commissioner of insurance, chief mine inspector and commissioner of charities and corrections. They are elected for a term of four years, and the governor, secretary of state, auditor and treasurer are ineligible for the next succeeding term. Other elected state officials are the three members of the corporation commission (one elected every two years for a six-year term), the clerk of the supreme court and four assistant mine inspectors. Administrative work is also done by more than 60 officers, commissions, departments and boards. The governor is a member of some important administrative boards, but the number of officers whom he appoints is rather limited and for most of his appointments the confirmation of the senate is required. His right of veto extends to items in appropriation bills, and to pass a bill over his veto a vote of two-thirds of the members elected to each house is required.

The legislative authority is vested in a senate of 44 members and a house of representatives (120 members in 1950), limited to 120 members. Half of the senators and all the representatives are elected every two years, senators by districts and representatives by counties. Sessions are held biennially in odd-numbered years and begin the first Tuesday after the first Monday in January. Oklahoma has put into its constitution many things which in the older states were left to legislation.

For the administration of justice there was established a supreme court, composed of nine justices elected for a term of six years; the supreme court commission of nine members appointed by the governor was discontinued after its work was completed; a criminal court of appeals composed of three justices elected one each two years, for a term of six years; 31 district courts, each with one or more justices elected for a term of four years; superior courts in certain of the more populous counties, with a judge elected for a term of four years; a county court in each county, with one judge elected for a term of two years; justice of the peace courts held by justices elected for a term of two years; and municipal courts in the cities. The supreme court has appellate jurisdiction in all civil cases, but its original jurisdiction is restricted to a general control of the lower courts. The supreme court commission, created by the legislature in 1927 to assist the supreme court in civil cases, was discontinued, as already explained. The criminal court of appeals has jurisdiction in all criminal cases appealed from the district and county courts. The district courts have exclusive jurisdiction in civil actions for sums exceeding $1,000, concurrent jurisdiction with the county courts in civil actions for sums greater than $500 and original or appellate in criminal cases. The superior courts were created to relieve the district courts and have a similar jurisdiction. The county courts have, besides the concurrent jurisdiction above stated, original jurisdiction in all probate matters, original jurisdiction in civil actions for sums greater than $200 and not exceeding $500, concurrent jurisdiction with the justices of the peace in misdemeanour cases and appellate jurisdiction in all cases brought from a justice of the peace or a police court.

Local Government.—The general management of county affairs is entrusted to three commissioners elected by districts. The other county officers are a sheriff, attorney, judge, clerk, court clerk, treasurer, assessor, surveyor, superintendent of public instruction and public weigher. They are chosen for a term of two years at the general elections in November. From 1919 only 21 counties had township government. The municipalities of Oklahoma may be classified as incorporated towns and as cities (more than 2,000 inhabitants).

Finances.—The revenues for state and for local purposes are derived almost wholly from separate sources. The greater part of the state's revenue is derived from a gross production tax on minerals, motor vehicle licences, a gasoline tax, insurance fees, an inheritance tax, an income tax, the sales tax and departmental collections. Revenue for local purposes is obtained chiefly from tax levies on personal and real property. The valuation and assessment of personal and real property and of public service corporations for 1948 was $1,648,594,702. This, however, did not include mineral property, taxed on gross production only, and allowance must be made also for an exemption of $1,000 on each homestead. There were no state levies on property in 1950, tax levies being made only by the counties, townships or cities and towns and school districts. The total revenue receipts, exclusive of federal grants, for the year ending June 30, 1948, were $182,612,145, of which $64,094,074 was returned to local governmental units. The chief state expenditures were for highways, education, debt amortization and service and penal institutions. The total bonded indebtedness of the state in 1949 was $17,757,781, but a bond issue of $36,000,000 was approved by popular vote in that year for the construction and repair of public buildings, especially those of hospitals and colleges. There were 383 banking institutions operating within the state in Sept. 1946. Their combined resources were $1,606,052,000 and their total deposits were $1,514,144,000. Of the total number of banks, 200 were national and 183 state banks.

Education.—Oklahoma has an excellent system of public education, and especially is this true for specialized and advanced instruction. The public-school system is administered by a state superintendent of public instruction, the co-ordinating board for higher institutions, several state boards of regents, the state board of agriculture, a state board of education, county superintendents and district boards. The state board of education, composed of the state superintendent and eight appointed members, apportions the state school-aid funds. The scholastic enumeration in 1948 showed 565,842 children of school age. Of this number 508,697 were enrolled in the public schools and 455,538 were in average daily attendance. The average number of days attended per enrolled pupil was 140; nearly all of the pupils were, however, enrolled in schools open 160 days or more. The number of pupils enrolled in the state high schools was 126,782, and in the private and parochial schools, 3,500 (est.). The total expenditure for schools in 1948 was $46,181,682. Of the total revenue receipts the state contributed $23,471,908; the rest came from local, county and benevolent sources. This was exclusive of aid from the federal government. Higher educational institutions supported by the state are the University of Oklahoma at Norman; Oklahoma Agricultural and Mechanical college, a land-grant college with experiment stations, at Stillwater; the Oklahoma College for Women, especially for domestic science and fine arts, at Chickasha; the Panhandle Agricultural and Mechanical college at Goodwell;

six state colleges at Durant, Edmond, Ada, Weatherford, Alva and Tahlequah; and Langston university (for Negroes) at Langston. Among the institutions of higher learning neither maintained nor controlled by the state are Phillips university at Enid; Oklahoma City university at Oklahoma City; Benedictine Heights college for women at Guthrie; the University of Tulsa at Tulsa; and Oklahoma Baptist university at Shawnee.

Charities and Corrections.—Under the constitution the supervision and inspection of charities and institutions of correction are in the hands of a state commissioner of charities and corrections, elected by the people.

The state-maintained institutions in 1950 were hospitals for the insane at Norman, Vinita and Supply; the University hospital at Oklahoma City; tubercular sanatoriums at Clinton and Talihina; orphanages for white children at Pryor and Helena; an institute for the feeble-minded at Enid; and a home for deaf, blind and orphan Negro children at Taft. The state penal institutions consisted of four training schools, for Negro girls at Taft, for Negro boys at Boley, for white girls at Tecumseh and for white boys at Stringtown; the Oklahoma state reformatory at Granite; and the state penitentiary at McAlester.

Agriculture and Stock Raising.—Prior to the first opening to settlement by white men in April 1889, the territory now comprising Oklahoma was a cattle country. Thereafter, although the opening was piecemeal, the agricultural development was remarkably rapid. By 1900, 51.1% of the total land surface was included in farms; and by 1930 the farm area was 33,791,000 ac., or approximately 76% of the total. The farm acreage in 1945 had increased to 36,161,872 or 81.6% of the total land area. The average size per farm then was 213.4 ac. The total number of farmers in 1945 was 164,790 as compared with 203,866 in 1930 and 191,988 in 1920. Of the total number of farm operators (164,790) in 1945, 153,586 were whites and 11,304 Negroes. In 1945, 18,004,630 ac. were worked by owners and 18,157,192 ac. by tenants. The total population residing on farms in 1945 was 639,948.

The value of lands and buildings in 1930 was $1,242,724,000; by 1945 the value had decreased to $1,106,154,000. The average value per farm in 1945 was $6,713. Of the 164,790 farms in 1945, 26,822 had running water, 45,387 had electricity, 39,810 had telephones and 119,252 had radios.

The total value of all crops in 1949 was $313,202,000, compared with $74,823,000 in 1940 and with $134,573,000 in 1930.

In the production of wheat in 1949, Oklahoma ranked third among states of the U.S., the state's production being exceeded by Kansas and North Dakota. The 1,300,000 ac. of cotton harvested in 1949 had a yield of 610,000 bales of lint and 246,000 tons of seed. The 6,825,000 ac. of wheat harvested in 1949 yielded 88,725,000 bu. Other important crops were Indian corn, 29,392,000 bu.; oats, 17,460,000 bu.; grain sorghums, 10,362,000 bu.; barley, 1,610,000 bu.; and rye, 297,000 bu.—in all cases the yields were below the ten-year average. The hay crop of 1,880,000 tons was harvested from 911,000 ac. of cultivated hay and 435,000 ac. of wild hay. The potato crop consisted of 814,000 bu. (ten-year average, 1,775,000 bu.) of white potatoes and 450,000 bu. (ten-year average, 639,000 bu.) of sweet potatoes. The production of peanuts in 1949 was 113,900,000 lb.

The livestock and poultry products of Oklahoma in 1948, according to the state board of agriculture, had a value of $345,259,000. Of this total $191,636,000 represented the value of the livestock slaughtered and sold for slaughter, and $45,303,000 the chickens and eggs produced. The value of turkeys produced came to $2,236,000. The livestock in the state on Jan. 1, 1950, consisted of 2,655,000 cattle of which 1,074,000 were kept for dairy purposes; 835,000 swine; 155,000 sheep; 213,000 horses; and 27,000 mules. The estimated value of livestock in the state was $300,000,000.

Minerals and Lumber Products.—The mineral production of the state in 1948 had a value of $503,654,000. The petroleum and natural gas producing regions of Oklahoma extend over about 40 counties from the north central to the southwestern parts of the state. In 1948 the greater number of Oklahoma's oil and gas fields were still producing. Tulsa, the oil centre of the state, is situated in about the centre of the north central producing area. The petroleum production in 1933 was 182,251,000 bbl. valued at $120,800,000; in 1948 it was 154,032,000 bbl. valued at $397,865,000. The 470,141,000 gal. of natural-gas gasoline produced in 1948 had a value of $36,411,000; and the 48•,573,000 cu.ft. of natural gas was valued at $23,356,000. The industry fourth in importance, ranked by value of product, was bituminous coal mining. The coal fields lie in the eastern part of the state and extend over a wide territory. The production in 1948 was 2,925,000 tons valued at $13,075,000. The industry fifth in importance was the mining of zinc ore in Ottawa county. The 1948 production was 43,821 tons valued at $11,656,386. The same region produced 16,918 tons of lead valued at $6,056,644. The balance of $15,234,000 came from miscellaneous products—asphalt, cement, clay, sand and gravel, stone, etc.

The lumber and lumber products industry, except furniture making, gave employment in 1947 to 2,324 persons. The value of production was $8,135,000. The cut of timber in 1947 was 82,793,000 bd.ft.

TABLE II.—*Manufactures*

Industry	Number of establishments	Number of wage earners	Value added
State total	1,740	55,403	$341,027,000
Petroleum and coal products	40	7,489	79,875,000
Chemical and allied products	76	1,589	12,127,000
Metal, primary and fabricated	115	6,895	35,304,000
Machinery (except electrical)	126	6,238	37,134,000
Stone, clay and glass products	86	4,373	23,411,000
Meat products	62	4,121	16,511,000
Grain-mill products	77	2,520	23,473,000
Dairy products	56	1,149	5,159,000
Bakery products	127	2,576	11,378,000
Printing and publishing	374	5,057	27,572,000

Manufactures and Transport.—Oklahoma ranks high among the states of the union in the production of raw materials; *i.e.*, products of farms, forests and mines. The total factory output (added value) came to $341,027,000 in 1947. The chief industrial centres of the state at mid-20th century were Oklahoma City, Tulsa, Muskogee, Enid and Shawnee.

The first railway in Oklahoma was the Missouri, Kansas and Texas, which completed a line across the Indian territory to Denison, Tex., in 1872. The railway mileage increased slowly until a part of the territory was opened to settlement (1889). From that time the mileage increased rapidly for several decades before declining. In 1950 the railway mileage was 7,877 and reached every part of the state. The principal lines crossing the state from north to south are the Missouri, Kansas and Texas, the St. Louis and San Francisco, the Atchison, Topeka and Santa Fe and the Chicago, Rock Island and Pacific. The Chicago, Rock Island and Pacific also crosses the middle of the state from east to west.

Oklahoma has approximately 100,000 mi. of public roads. Of this total, 10,143 mi. are included in the state-maintained highway system. By Jan. 1, 1950, 9,575 mi. of the state highways had been surfaced.

(R. GIT.)

OKLAHOMA CITY, capital and largest city of Oklahoma, U.S., and county seat of Oklahoma county; on the North Cana-

dian river, near the centre of the state. It is on federal highways 62, 66, 77, 270 and 277.

It is served by three air lines (American, Braniff and Continental) and by six railroads (Santa Fe, Rock Island, Frisco, Missouri-Kansas-Texas, Oklahoma City-Ada-Atoka and a belt railway) and by many bus and truck lines. The population in 1950 was 242,450, and in 1940, 204,424 by the federal census.

The site covers 47.7 sq.mi. and is about 1,200 ft. above sea level. The state capitol was completed in 1917 at a cost of $4,500,000.

It is an impressive colonnaded structure of white limestone, in 100 ac. of gardens and parkland, and completely surrounded by producing oil wells.

The large modern public and business buildings ranging up to 33 stories in height are beautified with borders of turf and shrubbery.

The residential streets are tree-lined and most of the houses set in spacious lawns and gardens.

The city's parklands cover 3,006 ac. Its water is supplied by two large reservoirs, Lake Hefner, with a capacity of 75,000 ac.ft., costing $9,500,000, and Lake Overholser with a capacity of 17,000 ac.ft., constructed at a cost of $6,000,000. The west edge of the city, inside the city limits, was selected as the site of a mile-square agricultural centre and state fair grounds. The city adopted a city-manager form of government in 1927. It is the seat of Oklahoma City university and of the medical school and hospitals of the University of Oklahoma, which has its main seat at Norman, 18 mi. S. Equally accessible is the Central State college at Edmond, 15 mi. N. In Oklahoma City's medical centre is a large Medical Research institute.

Oklahoma City is the commercial and financial metropolis of the state, the seat of a branch of the federal reserve bank, the home of insurance headquarters clearing 75% of the state's policies, and of wholesale houses doing nearly 50% of the state's wholesaling, a centre of a large trade area distributing petroleum products, oil-field equipment and supplies, automobiles, trucks and tractors, farm machinery and implements, drugs, hardware, appliances, clothing and food. It is one of the nation's largest cattle markets, and is the home of the Oklahoma 4-H and F.F.A. Livestock show.

The stockyards have a capacity of 62,000 head daily, and packing plants have an annual output valued at more than $140,000,000. There are producing oil fields on two sides of the city with some wells inside the city limits; many large operating companies have their headquarters here, and there are many supply houses doing a large business in serving the rich oil-producing areas of Oklahoma and the Texas panhandle.

The Civil Aeronautics administration aeronautical centre, where their technicians are trained, is located here, as is the Tinker air force base, which is the largest repair and supply depot of the U.S. air force.

The site of Oklahoma City was opened to settlement on April 22, 1889. By night it had a population of 10,000 under tents. The city was chartered in 1890 and became the capital of the state in 1910.

OKMULGEE, a city of eastern Oklahoma, U.S.A., on federal highways 75 and 62, also the Frisco and Okmulgee Northern railways; it is the county seat of Okmulgee county. Pop. (1950) 18,298 (85% native white, 14% Negro and 1% other); (1940) 16,051 by the federal census.

It is a centre of glass manufacturing, employing approximately 1,000.

Okmulgee is the home of large refineries and the county is rated as one of the more stable oil-producing counties in the state.

There are also peanut mills and a large beef cattle and dairy industry scattered through the county. In a square in the heart of the city stands the Council house which was the capital of the Creek nation for half a century.

Okmulgee was settled about 1900. In 1910 it was still a little cattle town of 4,176 inhabitants. In the next decade the population increased more than fourfold.

It was incorporated in 1912 under a commission-manager form of government.

OKRA: *see* GUMBO.

OKU, YASUKATA, MARSHAL, COUNT (1845–1930), Japanese general, was born in Fukuoka-ken. He commanded the 2nd army in the Russo-Japanese War.

In 1906–12 he was chief of the general staff, and was made count in 1907 and marshal in 1911.

OKUBO TOSHIMITSU (1830–1878), Japanese statesman, a samurai of Satsuma, was one of the five great nobles who led the revolution in 1868 against the shogunate. He became one of the mikado's principal ministers, and in the Satsuma troubles which followed he was the chief opponent of Saigo Takamori. But the suppression of the Satsuma rebellion brought upon him the personal revenge of Saigo's sympathizers, and in the spring of 1878 he was assassinated by six clansmen. Okubo was one of the leading men of his day, and in 1872 was one of the Japanese mission which was sent round the world to get ideas for organizing the new regime.

OKUMA (SHIGENOBU), MARQUIS (1838–1922), Japanese statesman, was born in the province of Hizen in 1838. His father was an officer in the artillery. He was able to acquire in his youth a knowledge of English and Dutch, and by the help of missionaries he obtained books in those languages on scientific and political subjects. These works effected a complete revolution in his mind.

He had been designed by his parents for the military profession, but he was determined to devote his energies to the abolition of the existing feudal system and to the establishment of a constitutional government. Though he took no active part in the revolution of 1868, the weight of his opinions was felt in the struggle. Already he was recognized as a coming man and no sooner was the government reorganized, with the mikado as the sole wielder of power, than he was appointed chief assistant in the department of foreign affairs.

In 1869 he succeeded to the post of secretary of the joint departments of the interior and of finance, and for the next 14 years he devoted himself to politics. In 1870 he was made a councillor of state, and a few months later became president of the commission which represented the Japanese government at the Vienna exhibition.

In 1872 he was again minister of finance, and was president of the commission appointed to supervise the Formosa campaign of 1874. The Japanese nation had supported him up to a certain point, but opinion now turned against him.

When Okuma resigned office in the early '80s he established the Semmon Gakko, or school for special studies, and subsequently other schools.

In 1896–97 he was a member of the Matsukata cabinet. An attempted assassination by bomb necessitated the amputation of one of his legs. On Ito's retirement in 1898 he took office as premier and minister of foreign affairs. He resigned after a few months and retired into private life, cultivating his beautiful garden at Waseda near Tokyo. He emerged from his retirement in 1914 to become prime minister, in which capacity he guided the country through the opening months of World War I. In 1916, Count Okuma retired from office owing to his failing health. In the same year he was raised to a marquessate. He died at Tokyo on Jan. 10, 1922.

OLAF or **ANLAF** (d. 981), king of the Danish kingdoms of Northumbria and of Dublin, was a son of Sitric, king of Deira, and was related to the English king Aethelstan. He was of Norse descent, and he married a daughter of Constantine II, king of the Scots. When Sitric died about 927 Aethelstan annexed Deira, and Olaf took refuge in Scotland and in Ireland until 937, when he was one of the leaders of the formidable league of princes which was destroyed by Aethelstan at the famous battle of Brunanburh. Again he sought a home among his kinsfolk in Ireland, but just after Aethelstan's death in 940 he or Olaf Godfreyson was recalled to England by the Northumbrians. Both crossed over, and in 941 the new English king, Edmund, gave up Deira to the former. The peace between the English and the Danes did not, however, last long. Wulfstan, archbishop of York, sided with Olaf; but in 944 this king was driven from Northumbria by

Edmund, and crossing to Ireland he ruled over the Danish kingdom of Dublin. From 949 to 952 he was again king of Northumbria, until he was expelled once more, and he passed the remainder of his active life in warfare in Ireland. But in 980 his dominion was shattered by the defeat of the Danes at the battle of Tara. He went to Iona, where he died probably in 981, although one account says he was in Dublin in 994. This, however, is unlikely. In the sagas he is known as Olaf the Red.

This Olaf must not be confused with his kinsman and ally, OLAF (d. 941), also king of Northumbria and of Dublin, who was a son of Godfrey, king of Dublin. The latter Olaf became king of Dublin in 934; but he was in England in 937, as he took part in the fight at Brunanburh. After this event he returned to Ireland, but he appears to have acted for a very short time as joint king of Northumbria with Olaf Sitricsson. It is possible that he was the "Olaf of Ireland" who was called by the Northumbrians after Aethelstan's death, but both the Olafs appear to have accepted the invitation. He was killed in 941 at Tyningham near Dunbar.

See W. F. Skene, *Celtic Scotland* (1876); J. R. Green, *The Conquest of England* (1899).

OLAF I. TRYGGVESSÖN (969–1000), king of Norway, was born in 969, and began his career in exile. It is even said that he was bought as a slave in Estonia. After a boyhood spent in Novgorod under the protection of King Valdemar, Olaf fought for the emperor Otto III. under the Wendish king Burislav, whose daughter he had married. On her death he raided the coasts of France and the British Isles, until he was converted to Christianity by a hermit in the Scilly Islands, and his marauding expeditions ceased since he would not harry those of his new faith. He married Gyda, sister of Olaf Kvaran, king of Dublin, and administered her property in England and Ireland for some time before he sailed for Norway, then restive under its ruler Earl Haakon. He was unanimously accepted as king of Norway (995), and began the conversion of the country to Christianity. Possibly Olaf's ambition was to rule a united, as well as a Christian, Scandinavia. He made overtures of marriage to Sigrid, queen of Sweden, and increased his fleet, but she clung to her heathen faith. He made an enemy of her, and involved himself in a quarrel with King Sveyn of Denmark by marrying his sister Thyre, who had fled from her heathen husband Burislav in defiance of her brother's authority. Both his Wendish and his Irish wife had brought Olaf wealth and good fortune, but Thyre brought him ill luck; in an expedition (1000) to wrest her lands from Burislav he was waylaid off the island Svöld, near Rügen, by the combined Swedish and Danish fleets, together with the ships of Earl Haakon's sons.

The battle ended in the annihilation of the Norwegians. Olaf fought to the last on his great vessel, the "Long Snake," the mightiest ship in the North, and finally leapt overboard and was no more seen. Full of energy and daring, skilled in the use of every kind of weapon, genial and open-handed to his friends, implacable to his enemies, Olaf's personality was the ideal of the heathendom which he repudiated and oppressed. After his death he remained the hero of his people, who looked for his return. "But however that may be," says the story, "Olaf Tryggvessön never came back to his kingdom in Norway."

OLAF (II.) HARALDSSÖN (995–1030), king of Norway from 1016–1029, called during his lifetime "the Fat," and afterwards known as St. Olaf, was born in 995, the year in which Olaf Tryggvessön came to Norway. After some years' absence in England, fighting the Danes, he returned to Norway in 1015 and declared himself king, obtaining the support of the five petty kings of the Uplands. In 1016 he defeated Earl Sveyn, hitherto the virtual ruler of Norway, at the battle of Nesje, and within a few years had won more power than had been enjoyed by any of his predecessors. He had annihilated the petty kings of the South, had crushed the aristocracy, enforced the acceptance of Christianity throughout the kingdom, asserted his suzerainty in the Orkney Islands, had humbled the king of Sweden and married his daughter in his despite, and had conducted a successful raid on Denmark. But in 1029 the Norwegian nobles, seething with discontent, rallied round the invading Knut the Great, and Olaf fled to Russia. On his return a year later he fell at the battle of Stiklestad, where his own subjects were arrayed against him. After his death his cunning and cruelty which marred his character were forgotten, and his services to his church and country remembered. Miracles were worked at his tomb, and in 1164 he was canonized and was declared the patron saint of Norway, whence his fame spread throughout Scandinavia and even to England, where churches are dedicated to him. The Norwegian order of knighthood of St. Olaf was founded in 1847 by Oscar I., king of Sweden and Norway, in memory of this king.

ÖLAND, an island in the Baltic sea, next to Gotland the largest belonging to Sweden, stretching for 85 m. along the east coast of the southern extremity of that country, from which it is separated by Kalmar Sound which is from 5 to 15 m. broad. The greatest breadth of the island is 10 m., and its area 519 sq.m. The centre of the island is more densely populated than either end. The only large town is Borgholm, with 2,041 inhabitants.

For administrative purposes the island of Öland is included in the Kalmar *län*. From the raid of Ragnar Lodbrok's sons in 775 Öland is frequently mentioned in Scandinavian history, and especially as a battleground in the wars between Denmark and the northern kingdoms. In the middle ages it formed a separate legislative and administrative unity. A number of monuments of unknown age exists, including stones (*stensättningar*) arranged in groups to represent ships. Borgholm has one of the finest castle ruins in Sweden. The town was founded in 1817, but the castle, dating at least from the 13th century, was one of the strongest fortresses, and afterwards one of the most stately palaces in the country. The inhabitants were formerly styled Öningar, and show considerable diversity of origin in the matter of speech, local customs and physical appearance.

The island consists for the most part of Silurian limestone, and thus forms a striking contrast to the mainland with its granite and gneiss. Down the west side runs a limestone ridge, rising usually in terraces, but at times in steep cliffs, to a height of 200 ft.; and along the east side there is a parallel ridge of sand, resting on limestone, never exceeding 90 feet. These ridges, known as the Western and Eastern Landborgar, are connected towards the north and the south by belts of sand and heath; and the hollow between them is occupied by a desolate and almost barren tract: the southern portion, or Alfvar (forming fully half of the southern part of the island), presents a surface of bare red limestone characteristically weathered. The northern portion is covered with hazel bushes. Outside the ridges, however, Öland is well wooded, while the narrow strip of alluvial coast-land is good agricultural country. There are a few small streams in the island and one lake, Hornsjö, about 3 m. long.

OLAUS MAGNUS or MAGNI (1490–1558) (Magnus, *i.e.*, *Stora*, great, being the family name, and not a personal epithet), Swedish ecclesiastic and author, followed his brother, Johannes Magnus, archbishop of Uppsala, to Rome in 1527. Most of his life, after his brother's death, seems to have been spent in the monastery of St. Brigitta in Rome, where he subsisted on a pension assigned him by the pope. He wrote the famous *Historia de Gentibus Septentrionalibus* (Rome, 1555), a work which long remained for the rest of Europe the chief authority on Swedish matters and is still a repertory of much curious information.

The *Historia* was translated into Italian (Venice, 1565), German (Strassburg, 1567), English (London, 1658) and Dutch (Amsterdam, 1665); abridgments of the work appeared also at Antwerp (1558 and 1562), Paris (a French abridged version, 1561), Amsterdam (1586), Frankfort (1618) and Leiden (1652). Olaus also wrote a *Tabula terrarum septentrionalium* . . . (Venice, 1539).

OLBERS, HEINRICH WILHELM MATTHIAS (1758–1840), German astronomer, was born on Oct. 11, 1758, at Arbergen, a village near Bremen, where his father was minister. He studied medicine at Göttingen, 1777–80, attending at the same time Kaestner's mathematical course. In 1779 he devised a new method of calculating cometary orbits. The treatise containing this important invention was made public by Baron von Zach under the title *Ueber die leichteste und bequemste Methode die Bahn eines Cometen zu berechnen* (Weimar, 1797). A table of 87

calculated orbits was appended, enlarged by Johann Encke in the second edition (1847) to 178, and by Johann Galle in the third (1864) to 242. In 1781 Olbers settled as a physician in Bremen, where he practised till his retirement on Jan. 1, 1823. The greater part of each night was meantime devoted to astronomy, the upper portion of his house being fitted up as an observatory. He paid special attention to comets, and that of 1815 (period 74 years) bears his name in commemoration of its detection by him. He also took a leading part in the discovery of the minor planets, rediscovering Ceres on Jan. 1, 1802, and discovering Pallas on March 28 following. His hypothesis of their origin by the disruption of a primitive large planet (*Monatliche Correspondenz,* vi, 88) seemed to gain confirmation by the finding of Juno by Harding, and of Vesta by himself, in regions indicated by the hypothesis. Olbers was deputed by his fellow citizens to assist at the baptism of the king of Rome on June 9, 1811, and he was a member of the *corps législatif* in Paris (1812–13). He died on March 2, 1840. He was twice married, and one son survived him.

See *Biographische Skizzen verstorbener Bremischer Aerzte,* by G. Barkhausen (Bremen, 1844); *Allgemeine geographische Ephemeriden,* iv, 283 (1799); *Abstracts Phil. Trans.,* iv, 268 (1843); *Astronomische Nachrichten,* xxii, 265 (Bessel), also appended to A. Erman's *Briefwechsel zwischen Olbers und Bessel,* 2 vol. (Leipzig, 1852); *Allgemeine deutsche Biographie* (S. Günther). The first two volumes of C. Schilling's exhaustive work *Wilhelm Olbers, sein Leben und seine Werke* appeared at Berlin in 1894 and 1900, a third and later volume including his personal correspondence and biography. A list of Olbers' contributions to scientific periodicals is given at p. xxxv of the 3rd ed. of his *Leichteste Methode,* and his unique collection of works relating to comets now forms part of the Pulkowa library.

OLD-AGE PENSIONS: *see* Pensions; Social Security.

OLDBURY, a municipal borough (1935) in the Stourbridge parliamentary division of Worcestershire, Eng., 5 mi. W. of Birmingham. It is served by the Western Region railway. Pop. (est. 1938) 45,450. Area 5.2 sq.mi. It is in the south Staffordshire coal field, and coal, iron and limestone are worked extensively. There are also chemical, tube, tool, wagon and brick works.

OLDCASTLE, SIR JOHN (d. 1417), English Lollard leader, son of Sir Richard Oldcastle of Almeley, Herefordshire, served in the expedition to Scotland in 1400. Next year he was in charge of Builth castle in Brecon, and serving all through the Welsh campaigns won the friendship and esteem of Henry, the prince of Wales. Oldcastle represented Herefordshire in the parliament of 1404. Four years later he married Joan, the heiress of Cobham, and was thereon summoned to parliament as Lord Cobham in her right. Oldcastle held a high command in the expedition which the young Henry sent to France in 1411. Oldcastle had adopted Lollard opinions before 1410, when the churches on his wife's estates in Kent were laid under interdict for unlicensed preaching. In the convocation which met in March 1413, shortly before the death of Henry IV, Oldcastle was at once accused of heresy. But his friendship with the new king prevented any decisive action till evidence was found in a book belonging to Oldcastle, which was discovered in a shop in Paternoster row.

Oldcastle declared his readiness to submit to the king "all his fortune in this world," but was firm in his religious beliefs, and Henry at last consented to a prosecution. It was only under a royal writ that Oldcastle at last appeared before the ecclesiastical court on Sept. 23. In a confession of his faith he declared his belief in the sacraments and the necessity of penance and true confession; but to put hope, faith or trust in images was the great sin of idolatry. He would not assent to the orthodox doctrine of the sacrament as stated by the bishops, nor admit the necessity of confession to a priest. He was convicted as a heretic Sept. 25. Henry granted a respite of 40 days in the hope of saving his friend.

Before that time had expired Oldcastle escaped from the Tower by the help of one William Fisher, a parchment maker of Smithfield (Riley, *Memorials of London,* 1868). He now put himself at the head of a widespread Lollard conspiracy. The design is said to have included the seizure of the king and his brothers during a Twelfth-night mumming at Eltham. Henry, forewarned, removed to London, and when the Lollards assembled in force in St. Giles's Fields on Jan. 10 they were easily dispersed. Oldcastle himself escaped into Herefordshire, and for nearly four years avoided capture. He took part in several conspiracies. In Nov. 1417 he was captured by the Lord Charlton of Powis. On Dec. 14 he was formally condemned, on the record of his previous conviction, and was hanged that same day in St. Giles's Fields, and burned "gallows and all." Oldcastle died a martyr. At the same time his execution can be justified on political grounds. His opinions and early friendship with Henry V created a traditional scandal which long continued. In the old play *The Famous Victories of Henry V,* written before 1588, Oldcastle figures as the prince's boon companion. When Shakespeare adapted that play in *Henry IV,* Oldcastle still appeared; but when the play was printed in 1598 Falstaff's name was substituted, in deference, as it is said, to the then Lord Cobham. Though the fat knight still remains "my old lad of the Castle," the stage character has nothing to do with the Lollard leader.

Bibliography.—The record of Oldcastle's trial is printed in *Fasciculi Zizaniorum* (Rolls series) and in Wilkins' *Concilia,* iii, 351–357. The chief contemporary notices of his later career are given in *Gesta Henrici Quinti* (English Historical Society) and in Walsingham's *Historia Anglicana.* There have been many lives of Oldcastle, mainly based on *The Actes and Monuments* of John Foxe, who in his turn followed the *Briefe Chronycle* of John Bale, first published in 1544. For notes on Oldcastle's early career, consult J. H. Wylie, *History of England under Henry IV.* For literary history *see* the Introductions to Richard James's *Iter Lancastrense,* Chetham Society (1845), and to Grosart's edition of the *Poems of Richard James* (1880). *See* also W. Barske, *Oldcastle-Falstaff in der englischen Literatur bis zu Shakespeare* (Palaestra, I. Berlin, 1905); and W. T. Waugh in the *English Historical Review,* vol. xx.

OLD CATHOLICS, the sect which took its origin in a group of Roman Catholic opponents to the Vatican council's definition of the dogma of papal infallibility in 1870. Old Catholics characterized the dogma as *new* and as opposed to the rights and the traditional faith of the *old* church which they claimed to represent. Above all other countries, Germany displayed the most marked and intensive opposition. On Aug. 27, 1870, representatives from the Universities of Munich, Bonn, Breslau, Braunsberg and Prague met at Nuernberg under the presidency of Johann J. I. von Döllinger and issued a formal protest in five resolutions against the Vatican decree. On Aug. 30 the Catholic bishops of Germany, assembled in a national synod at Fulda, issued a pastoral letter promulgating the decrees of the Vatican council. In Oct. 1870 the archbishop of Munich requested the views of his theological faculty on the decrees. Johannes Friedrich refused to submit and Döllinger refused to answer. Finally in his "Declaration to the Archbishop of Munich" on March 28, 1871, Döllinger answered that "neither as a Christian, nor as a theologian, nor as an historian, nor as a citizen, could he accept the dogma of papal infallibility." He was excommunicated on April 17, and Friedrich's excommunication followed on April 19.

Opposition now turned to rebellion. Döllinger had the active and energetic support of fellow priests: Reusch, Langen, Knoodt of Bonn, Reinkens of Breslau and Michelis of Braunsberg. Two central committees were formed to organize the rebellion, one in Cologne for the north, the other in Munich for the south of Germany. Michelis toured Germany and Austria fomenting rebellion, while Johann F. von Schulte, formerly professor of canon and German law at the University of Prague and, after his apostasy, appointed by the Prussian government to a professorship at Bonn, became the legal adviser of Old Catholicism and the apologist of the state in its *Kulturkampf* with the Church of Rome.

So well had Schulte organized the rebellious groups that the first Old Catholic congress met at Munich, Sept. 22–24, 1871; 300 representatives convened from Germany, Austria and Switzerland as well as delegates from the English and Russian Churches. A central commission was set up to prepare the way for intercommunion with other Christian churches and for the organization of an independent Old Catholic sect. Döllinger warned the congress not to "raise up altar against altar" and thus to brand themselves as a new sect, but rather to remain, as they claimed to be, members of the Catholic Church. His was the sole

vote cast against the formation of a pastorate and parishes.

At the second congress, which met at Cologne, Sept. 20–22, 1872, a committee was appointed to arrange for the election of a bishop. Döllinger held aloof from Old Catholicism as a sect but accepted the chairmanship of the committee for the intercommunion of Christian churches. Resolutions were passed for the organization of parishes. Schulte obtained Bismarck's consent to the election of a bishop and on June 4, 1873, Joseph H. Reinkens was elected bishop. After the death of the Jansenistic Archbishop Loos of Utrecht, who had been invited to perform the consecration, the function was performed at Rotterdam, Aug. 11, 1873, by Bishop Heykamp of Deventer and a bishopric was established at Bonn. Bishop Reinkens then issued a pastoral in which he claimed to be the only legitimate Catholic bishop in Germany. Prussia, Baden and Hesse recognized this claim; and, through the exertions of Schulte, Prussia and Baden granted the Old Catholics many Roman Catholic churches and gave them title to a legal share of Roman Catholic church property.

Old Catholicism modelled its organization on the Protestant churches: annual synods composed of clergy and laymen were prescribed; mixed synodal commissions were appointed; a bishop was elected to ordain the clergy and to confirm. During the course of annual synods radical changes were made in discipline and dogma which completely separated Old Catholicism from Roman Catholicism. In 1874 confession, fasting and holy days were abolished; in 1875, to facilitate intercommunion with Protestant churches, tradition was abandoned and the authority of the deuterocanonical books was questioned, indulgences were rejected, the validity of Anglican orders was recognized and the *Filioque* dropped from the creed. In 1878, despite the warnings of the Jansenists and the Bavarian representatives, a resolution was carried abolishing clerical celibacy. Finally, in 1880 the Latin was supplanted by the vernacular liturgy.

In the hope that Old Catholicism would nationalize the church in Germany, the leaders of the *Kulturkampf* afforded Old Catholics wholehearted support and assistance. However, after the first 15 years the friendly governments recognized that Old Catholicism was no longer a schism but rather another Protestant sect. The number of Old Catholics had rapidly diminished, and as the bitterness of the *Kulturkampf* declined, less interest was displayed by statesmen toward the movement. In 1880 there were about 50,000 adherents in Germany; in 1910 there were 58 parishes and about 20,000 members; this number remained constant until World War II. Post-World War II figures were not available at mid-20th century.

Upon the definition of papal infallibility, the Liberal government in Austria rejected the concordat of 1855 and forbade the publication of the Vatican decrees. Refusing to recognize the jurisdiction of Bishop Reinkens, the Austrian Old Catholics erected a community in Vienna and appointed Aloysius Anton Nittel as pastor (1881–88). At first refused legal recognition by the government, they received on Nov. 8, 1878, through the energy of Schulte, a legal status under the title of Old Catholic Church. In the beginning a bishop was deemed unnecessary; later Amandus Czech (1888–1922) was elected, but not consecrated, bishop, since the government withheld its consent until an adequate episcopal fund was established.

The first bishop was Adalbert Schindelar (1925–26), who was succeeded by Robert Tüchler as overseer (1926–28) and finally as bishop (1928). Although they numbered but 10,000 in the beginning, assisted in Bohemia and Styria by the *Los von Rom* movement, in 1901 Austrian Old Catholics counted 24 parishes and about 16,000 adherents, about .1% of the total Austrian population. Before World War II there were 12 Old Catholic parishes in Austria with 31,000 members, of whom 23,635 resided in Vienna (later figures were not available). Czechoslovakia had 12 parishes and 20,000 members, with Alois Paschek (1928) as their first bishop.

Though Switzerland had previously bitterly opposed the definition of papal infallibility, in 1870 only three priests formally separated from the Roman Catholic communion; viz., Schwind, Egli and Herzog. Hoping that the Old Catholic movement would establish a national church broad enough to embrace all Christian churches, the governments of the Protestant cantons protected the dissident clergy and invoked harsh measures against Roman Catholic priests. The Old Catholic schism was legally recognized April 9, 1874. A committee was appointed on July 29 to establish an Old Catholic faculty of theology at Berne. On Nov. 23, 1874, under the dean, Friedrich, courses opened and eight students attended. Attempts were made to unite all the Old Catholic communities in Switzerland, but the titles "Old Catholic" and "Liberal Catholic" were rejected in an assembly held at Berne in 1874. On Feb. 28, 1875, however, the Old Catholic communities were organized into a "Christian Catholic National Church." In 1876 Eduard Herzog, the bishop-elect, was consecrated by Bishop Reinkens and Berne became his episcopal residence. By 1878 the Roman Catholics were strong enough to outvote the Old Catholics in the election to local church committees and thus regained possession of their former churches.

Geneva was the centre of severe persecutions of Roman Catholics. Refusing to take the prescribed oath, the Roman Catholic clergy were banished from the city and Père Hyacinthe Loyson was appointed pastor of Geneva. In 1876 the Old Catholics of Switzerland abolished confession and clerical celibacy and permitted the vernacular liturgy. Gradually they abandoned Roman Catholic dogma and discipline in the attempted intercommunion with the Protestant churches of England, Scotland and America. Old Catholicism became indistinguishable from other Swiss Protestant sects. Adolf Küry succeeded Bishop Herzog in 1924.

In Italy, Spain and France the attempts to organize Catholic national churches met with little popular sympathy and no church organization. In North America the Old Catholic movement was initiated by Joseph René Vilatte, a Parisian and Roman Catholic by birth. Vilatte apostatized while studying for the priesthood in Canada, and later became a Presbyterian minister and the pastor of a congregation in northern Wisconsin. Dissatisfied, he sought advice from Père Hyacinthe Loyson and was eventually ordained priest by the Old Catholic bishop Eduard Herzog in 1885. Returning to Wisconsin he spread Old Catholicism among the Belgian communities. Refused episcopal consecration by Bishop Herzog through the animosity of the Anglican bishop Grafton, Vilatte was consecrated by F. X. Julius Alvarez, the schismatic archbishop of Ceylon, Goa and India in 1891.

Vilatte attempted to gain the active support of the Polish schismatic priests Anthony Kozlowski of Chicago and S. Kaminski of Buffalo. Kozlowski was consecrated bishop in Nov. 1897 by Bishop Herzog at Berne and became the leader of the North American Old Roman Catholic Church. Vilatte led the Old Roman Catholic Church. Four Old Catholic bodies were registered in the United States: American Catholic Church (founded in May 1927 by James F. A. Lashley); American Old Catholic Church Incorporated (sprung from the Old Catholic Church of Utrecht in the Netherlands); North American Old Roman Catholic Church (founded June 14, 1912, by its first archbishop, De Landas Berghes, who was consecrated Oct. 4, 1916, and was succeeded by his coadjutor, Carmel Carfora, in 1919); and Old Catholic Church in America.

(C. W. R.)

OLDENBARNEVELDT, JOHAN VAN (1547–1619), Dutch statesman, was born at Amersfoort on Sept. 14, 1547. After studying law at Louvain, Bourges and Heidelberg, and travelling in France and Italy, Oldenbarneveldt settled down to practise in the law courts at The Hague. In religion a moderate Calvinist, he became a zealous adherent of William the Silent. He served as a volunteer for the relief of Haarlem (1573) and again at Leyden (1574). In 1576 he became pensionary of Rot-

terdam. He was active in promoting the Union of Utrecht (1579) and the acceptance of the countship of Holland and Zeeland by William (1584). On the assassination of William it was at the proposal of Oldenbarneveldt that the youthful Maurice of Nassau was at once elected stadholder, captain general and admiral of Holland. During the governorship of Leicester he was the leader of the strenuous opposition offered by the states to the centralizing policy of the governor.

In 1586 he was appointed, in succession to Paul Buys, to the post of land's advocate of Holland. Nominally the servant of the states of Holland he made himself politically the personification of the province which bore more than half the entire charge of the union, and as its mouthpiece in the states-general he practically dominated that assembly.

During the two critical years which followed the withdrawal of Leicester, he prevented the disintegration of the United Provinces, which might otherwise have fallen an easy conquest to the army of Alexander of Parma. Fortunately for the Netherlands the attention of Philip of Spain was at that time riveted upon his contemplated invasion of England, and Oldenbarneveldt had time to gather into his own hands the control of administrative affairs. He was wholeheartedly supported by Maurice of Nassau, who, after 1589, held the stadholderate of five provinces, and was likewise captain general and admiral of the union. The first rift between them came in 1600, when Maurice was forced against his will by the states-general, under the advocate's influence, to undertake an expedition into Flanders, which was saved from disaster only by desperate efforts which ended in victory at Nieuwport. In 1598 Oldenbarneveldt took part in special embassies to Henry IV and Elizabeth, and again in 1605 in a special mission sent to congratulate James I on his accession.

The opening of negotiations by Albert and Isabel in 1606 for a peace or long truce led to a great division of opinion in the Netherlands. The archdukes having consented to treat with the United Provinces "as free provinces and states over which they had no pretensions," Oldenbarneveldt, who had with him the states of Holland and the majority of burgher regents throughout the country, was for peace, provided that liberty of trading was conceded. Maurice and his cousin William Louis, stadholder of Frisia, with the military and naval leaders and the Calvinist clergy, were opposed to it, on the ground that the Spanish king was merely seeking an interval of repose in which to recuperate his strength for a renewed attack on the independence of the Netherlands. For three years the negotiations went on, but at last after endless parleying, on April 9, 1609, a truce for 12 years was concluded. All that the Dutch asked was directly or indirectly granted, and Maurice gave a reluctant assent to the favourable conditions obtained by Oldenbarneveldt.

Religious Differences and the Sequel.—The now "free and independent state" was rent by internal differences between the Remonstrants (Arminians) and Contra-Remonstrants (Gomarists); the states of Holland under the influence of Oldenbarneveldt supported the former, and refused to sanction the summoning of a purely church synod (1613). They likewise (1614) forbade the preachers in the province of Holland to treat of disputed subjects from their pulpits. Obedience was difficult to enforce without military help, riots broke out in certain towns, and when Maurice was appealed to, as captain general, he declined to act. He did more, though in no sense a theologian; he declared himself on the side of the Contra-Remonstrants, and established a preacher of that persuasion in a church at The Hague (1617).

The advocate now took a bold step. He proposed that the states of Holland should, on their own authority, as a sovereign province, raise a local force of 4,000 men (*waardgelders*) to keep the peace. The states-general meanwhile by a bare majority (four provinces to three) agreed to the summoning of a national church synod. The states of Holland, also by a narrow majority, refused their assent to this, and passed (Aug. 4, 1617) a strong resolution (*Scherpe Resolutie*) by which all magistrates, officials and soldiers in the pay of the province were required to take an oath of obedience to the states on pain of dismissal, and were to be held accountable not to the ordinary tribunals, but to the states of Holland. It was a declaration of sovereign independence on the part of Holland, and the states-general took up the challenge and determined on decisive action. A commission was appointed with Maurice at its head to compel the disbanding of the *waardgelders*. On July 31, 1618, the stadholder appeared at Utrecht, which had thrown in its lot with Holland, at the head of a body of troops, and at his command the local levies at once laid down their arms. His progress through the towns of Holland met with no opposition. The states party was crushed without a blow being struck. On Aug. 23, by order of the states-general, the advocate and his chief supporters, Hugo Grotius and Hoogerbeets, were arrested.

Oldenbarneveldt was with his friends kept in the strictest confinement until November, and then brought for examination before a commission appointed by the states-general. He appeared more than 60 times before the commissioners, and was, most unjustly, allowed neither to consult papers nor to put his defense in writing. On Feb. 20, 1619, he was arraigned before a special court of 24 members, only half of whom were Hollanders, and nearly all of them his personal enemies. It was in no sense a legal court, nor had it any jurisdiction over the prisoner, but the protest of the advocate, who claimed his right to be tried by the sovereign province of Holland, whose servant he was, was disregarded. He was allowed no advocates, nor the use of documents, pen or paper. It was in fact not a trial at all, and the packed bench of judges on Sunday, May 12, pronounced sentence of death. On the following day the old statesman, at the age of 71, was beheaded in the Binnenhof at The Hague.

Not a shred of evidence has ever been produced to throw suspicion upon the patriot statesman's conduct. All his private papers fell into the hands of his foes, but not even the bitterest and ablest of his personal enemies, Francis Aarssens (*q.v.*), could extract from them anything to show that Oldenbarneveldt at any time betrayed his country's interests. His high-handed course of action in defense of what he conceived to be the sovereign rights of his own province of Holland to decide upon religious questions within its borders may be challenged on the ground of inexpediency, but not of illegality.

The harshness of the treatment meted out by Maurice to his father's old friend, the faithful counsellor and protector of his own early years, leaves a stain upon the stadholder's memory. That the prince should have felt compelled in the last resort to take up arms for the union against the attempt of the province of Holland to defy the authority of the generality may be justified by the plea *reipublicae salus suprema lex*. To eject the advocate from power was one thing, to execute him as a traitor quite another. The condemnation of Oldenbarneveldt was carried out with Maurice's consent and approval, and he cannot be acquitted of a prominent share in what posterity has pronounced to be a judicial murder.

Oldenbarneveldt was married in 1575 to Maria van Utrecht. He left two sons, the lords of Groeneveld and Stoutenburg, and two daughters. A conspiracy against the life of Maurice, in which the sons of Oldenbarneveldt took part, was discovered in 1623. Stoutenburg, who was the chief accomplice, made his escape and entered the service of Spain; Groeneveld was executed.

OLDENBURG, a *Land* of Germany, with an area of 2,084 sq.mi. It consisted until 1937 of three widely separated provinces: (1) Oldenburg, (2) Lübeck and (3) Birkenfeld. It had one vote in the German *reichsrat.*

Oldenburg proper was bounded on the north by the North sea and on the other three sides by Hanover, with the exception of a small strip on the east, where it was conterminous with the territory of the free city of Bremen. It formed part of the northwestern German plain lying between the Weser and the Ems.

The climate is temperate and humid; the mean temperature of the coldest month at the town of Oldenburg is 26° F., of the warmest 66°. Storms are numerous and fogs and ague are prevalent in the marshlands. The chief rivers are the Hunte, flowing into the Weser, and the Hase and Leda flowing into the Ems. The Weser itself formed the eastern boundary for 42 mi., and internal navigation is facilitated by a canal connecting the Hunte and the Leda. On the north there are several small coast streams conducted through the dikes by sluices. Large tracts of moorland, however, are useful only as producing peat for fuel, or as affording pasture to the flocks of small coarse-woolled Oldenburg sheep. The rich soil of the marshlands produces good crops of wheat, oats, rye, hemp and rape, but is especially adapted for grazing. The mineral wealth of Oldenburg is very small. Woollen and cotton fabrics, stockings, jute and cigars are made at Varel, Delmenhorst and Lohne; cork cutting is extensively practised in some districts, and there are a few iron foundries. Trade is relatively of more importance, chiefly owing to the proximity of Bremen.

Lübeck.—The former principality of Lübeck had an area of 209 sq.mi. and shared in the general physical characteristics of east Holstein, within which it lies. The population was 47,494. In 1937, by an exchange of territories for the sake of administrative simplification, the Lübeck territories enclaved in Oldenburg were annexed to Oldenburg, and the rest of the Lübeck lands, including the Hanseatic city itself, were annexed to the Prussian province of Schleswig-Holstein. The Birkenfeld enclave in Prussia was annexed to the Prussian Rhine province.

Birkenfeld.—The former principality of Birkenfeld, 312 sq.mi. in extent, lies in the midst of the Prussian province of the Rhine, about 30 mi. W. of the Rhine at Worms and 150 mi. S. of the duchy of Oldenburg. The population was 55,649.

General Features.—The total population of the *Land* of Oldenburg in 1939 was 582,402. The bulk of the inhabitants are of Saxon stock, but to the north and west of the *Land* there are numerous descendants of the ancient Frisians. Low German (*Platt-deutsch*) is universally spoken, except in one limited district, where a Frisian dialect has maintained itself.

Oldenburg is mainly a Protestant country, but Roman Catholicism preponderates in the southwestern provinces, which formerly belonged to the bishopric of Münster, and Oldenburg Roman Catholics are under the sway of the bishops of Münster.

The constitution of 1919 provided for a single representative chamber (*landtag*), elected by universal suffrage and exercising rights of legislation and taxation. The chamber, which consisted of 48 members, was elected every three years.

History.—The descendants of Elimar (d. 1108), the first historical count of Oldenburg, attained the dignity of princes of the empire when the emperor Frederick I dismembered the Saxon territory in 1180. The free city of Bremen and the bishop of Münster were frequently at war with the counts of Oldenburg.

Count Christian, who in 1448 was chosen king of Denmark as Christian I, became king of Norway in 1450 and in 1457 king of Sweden. In 1460 he inherited the duchy of Schleswig and the county of Holstein, an event of high importance for the future history of Oldenburg. In 1454 he handed over Oldenburg to his brother Gerhard (*c.* 1430–99). Count Anton Günther (1583–1667), who succeeded in 1603, proved himself the wisest prince who had yet ruled Oldenburg. By his prudent neutrality during the Thirty Years' War he secured for his dominions an immunity from the terrible devastations to which nearly all the other states of Germany were exposed. He also obtained from the emperor the right to levy tolls on vessels passing along the Weser, a lucrative grant which soon formed a material addition to his resources. From 1702 to 1773 the county was ruled by the kings of Denmark, this period being on the whole one of peaceful development. In the latter year Frederick Augustus, bishop of Lübeck, a kinsman of the emperor Paul of Russia, became count, and in 1777 the county was raised to the rank of a duchy. In 1815 the title of grand duke was allowed to the reigning duke, in consideration of his services to the allies, but was not taken up till 1829. In 1871 Oldenburg became a state of the new German empire and in 1918 the grand ducal family was expelled by the German revolution.

For the history of Oldenburg *see* Runde, *Oldenburgische Chronik* (Oldenburg, 1863); E. Pleitner, *Oldenburg im 19 Jahrhundert* (Oldenburg, 1899–1900); and *Oldenburgisches Quellenbuch* (Oldenburg, 1903). *See* also the *Jahrbuch für die Geschichte des Herzogtums Oldenburg* (1892 *et seq.*).

OLDENBURG, a town of Germany, and capital of the province of Oldenburg, situated 27 mi. by rail W. of Bremen, on the navigable Hunte and the Hunte-Ems canal. Pop. (1939), including the suburbs, 78,506. According to popular tradition Oldenburg was founded by Walbert, grandson of the Saxon hero Widukind, and was named after his wife Altburga, but the first historical mention of it occurs in a document of 1108. It was fortified in 1155, and received a municipal charter in 1345. The Evangelical Lambertikirche, though dating from the 13th century, was transformed in 1874–86. The former palaces of the grand duke and the old town hall are Renaissance buildings of the 17th and 18th centuries. The picture gallery includes works by Paolo Veronese, Diego Rodriguez de Silva y Velasquez, Bartolomé Esteban Murillo and Peter Paul Rubens.

OLDESLOE: *see* BAD OLDESLOE.

OLDFIELD, ANNE (1683–1730), English actress, was born in London, the daughter of a soldier. She was apprenticed to a seamstress, but, fortunately, she attracted George Farquhar's attention by reciting some lines from a play in his hearing. She was engaged at Drury lane in 1692, and ten years later she was generally acknowledged as the best actress of her time. Mrs. Oldfield's beauty and generosity found innumerable eulogists, as well as sneering detractors. Alexander Pope, in his *Sober Advice from Horace,* wrote of her:

> "Engaging Oldfield, who, with grace and ease,
> Could join the arts to ruin and to please."

She died at 47 on Oct. 23, 1730, and was buried in Westminster abbey.

OLD FORGE, an anthracite-mining borough of Lackawanna county, Pa., U.S., on the Lackawanna river, 4 mi. S.W. of Scranton; served by the Erie, Lehigh Valley, Ontario Western and Lackawanna railways. Pop. (1950) 9,745. Old Forge was settled in 1789 and incorporated as a borough in 1899.

OLDHAM, JOHN (1653–1683), English satirist, son of a Presbyterian minister, was born at Shipton Moyne, near Tetbury, Gloucestershire, on Aug. 9, 1653. He graduated from St. Edmund hall, Oxford, in 1674, and was for three years an usher in Whitgift's school at Croydon. In 1681 he became tutor to the grandsons of Sir Edward Thurland, near Reigate. *Garnet's Ghost* was published as a broadside in 1679, but the other *Satires on the Jesuits,* although written at the same time, were not printed until 1681. His undoubted services to the Country party brought no reward from its leaders. Eventually he became chaplain to William Pierrepont, earl of Kingston. He died at Holme-Pierrepoint, near Nottingham, on Dec. 9, 1683.

Oldham took Juvenal for his model, and in breadth of treatment and power of invective surpassed his English predecessors. Thomas Garnet, who suffered for supposed implication in the Gunpowder plot, rose from the dead to encourage the Jesuits in the first satire, and in the third Ignatius Loyola is represented as dictating his wishes to his disciples from his deathbed. Oldham's verse is rugged, and his rhymes often defective, but he met with a generous appreciation from Dryden.

The best edition of his works is *The Compositions in Prose and Verse of Mr. John Oldham . . .* (1770), with memoir and explanatory notes by Edward Thompson; *see* also *Poems,* ed. with memoir by R. Bell (1891).

OLDHAM, THOMAS (1816–1878), British geologist, was born in Dublin, Ire., on May 4, 1816. He studied at Dublin and Edinburgh, and in 1839 became chief assistant in the geological department of the ordnance survey, where he helped to prepare the *Report on the Geology of Londonderry* (1843). Appointed professor of geology in Dublin university in 1845, he became director of the geological survey of Ireland in 1846, and two years later F.R.S. The fossil named *Oldhamia* was discovered by him in the Cambrian rocks of Bray head in 1849. In 1850 he was put in charge of the geological survey of India, which led him to pub-

lish, in 1864, a report on the coal resources of India. He retired in 1876, and died at Rugby on July 17, 1878.

OLDHAM, municipal, county and parliamentary borough, Lancashire, Eng., 7 mi. N.E. of Manchester, on the London Midland Region railway and the Oldham canal. Population (1951) 121,212. The principal railway station is called Mumps, but there are several others. The town lies high, near the source of the small river Medlock. Its growth as a manufacturing centre gives it a wholly modern appearance. The oldest church dates from the later 18th century. The principal buildings and institutions include the town hall, with tetrastyle portico, the reference library, art gallery and museum, the Union street baths and the county court. The Lyceum contains schools of art and science, and an observatory; the largely endowed bluecoat school was founded in 1808 by Thomas Henshaw. The Alexandra park, opened in 1865, stands on a picturesquely undulating and terraced site. Oldham is one of the most important centres of the cotton manufactures. The principal manufactures are fustians, velvets, cords, shirtings, sheetings and nankeens. There are also large foundries, mill and cotton machinery works and engineering works of various kinds. Oldham, incorporated in 1849, became a county borough in 1888. The parliamentary borough has returned two members since 1832. Area 7.4 sq.mi.

A Roman road, of which traces are still left, passes through the township. It is not mentioned in Domesday, but in the reign of Henry III Alwardus de Aldholme is referred to as holding land in Vernet (Werneth). A daughter of this Alwardus conveyed Werneth hall and its manor to the Cudworths, a branch of the Yorkshire family, with whom it remained till the 18th century. From the Oldhams was descended Hugh Oldham, who died bishop of Exeter in 1519. It appears that linens were manufactured in Oldham as early as 1630. Watermills were introduced in 1770, and with the adoption of Richard Arkwright's inventions the cotton industry grew with great rapidity.

OLDMIXON, JOHN (1673–1742), English historian, was a son of John Oldmixon of Oldmixon, near Bridgwater. He wrote a number of miscellaneous works, but his most important book is his *Critical History of England* (1724–26), which contains attacks on Clarendon and a defense of Bishop Gilbert Burnet. Its publication led to a controversy between Zachary Grey and the author, who replied to Grey in his *Clarendon and Whitlock compared* (1727). In his *History of England during the Reigns of the Royal House of Stuart* (1730) he charged Bishop Francis Atterbury and other of Clarendon's editors, unjustly, with tampering with the text of the *History*. He completed a continuous history of England by writing the *History of England during the Reigns of William and Mary, Anne and George I* (1735); and the *History of England during the Reigns of Henry VIII, Edward VI, Mary and Elizabeth* (1739). Oldmixon died on July 9, 1742.

OLD OREGON TRAIL, an American pioneer route, from Independence, Mo., to The Dalles, Columbia river, Oregon, about 2,000 mi. long, long used by the immigrants from the Mississippi valley to the northwest. Blazed in part by trappers, the Lewis and Clarke expedition and the Frémont survey, between 1805 and 1842, it followed the North Platte and its tributary the Sweetwater, went through South pass in the Rocky mountains and proceeded by way of Fort Laramie, Independence rock and Great Salt lake to the vicinity of Oregon City.

The name Oregon trail is given to a modern highway following a somewhat different route.

OLD POINT COMFORT, a summer and winter resort, in Elizabeth City county, Va., U.S., at the southern end of a narrow, sandy peninsula projecting into Hampton roads (at the mouth of the James river), about 12 mi. N. by W. of Norfolk. It is served indirectly by the Pennsylvania railroad, passengers and freight being carried by steamer from the terminus at Cape Charles; by steamboat lines connecting with the principal cities along the Atlantic coast, and with cities along the James river; and by ferry, connecting with Norfolk and Portsmouth.

There is a U.S. garrison at Fort Monroe, one of the most important permanent fortifications on the Atlantic coast of the United States. The fort was first regularly garrisoned in 1823; in 1824 the Artillery School of Practice (later called the U.S. Coast Artillery school) was established to provide commissioned officers of the coast artillery with instruction in professional work and to give technical instruction to the noncommissioned staff. During the Civil War the fort was the rendezvous for several military expeditions, notably those of Gen. B. F. Butler to Hatteras inlet, in 1861; of Gen. A. E. Burnside to North Carolina, in 1862; and of Gen. A. H. Terry, against Fort Fisher, in 1865. Jefferson Davis was a prisoner there for two years; his cell was restored and dedicated in 1951. The expedition which settled Jamestown rounded the peninsula (April 26, 1607), opened its sealed instructions there and named the peninsula "Poynt Comfort," in recognition of the sheltered harbour. The "Old" was added subsequently to distinguish it from a Point Comfort settlement at the mouth of the York river on Chesapeake bay.

OLD SLAVONIC. By the language called Old Bulgarian or Old (Church) Slavonic, and here abbreviated as O.B., is meant that first fixed in writing toward the end of the 9th century, when, at the request of the Moravian prince Rostislav, the Byzantine emperor Michael III decided to send emissaries (Constantine, afterward called Cyril—d. 869—and Methodius, his brother —d. 887) to convert the population of Moravia to Christianity. The term "Old Slavonic," frequently used by French and Czech scholars, is liable to misinterpretation as it may be confused with Common Slavonic, the postulated ancestral form of all the Slav languages, or be taken to refer to the earlier form of any particular Slavonic language. The expression "Old Church Slavonic," used by many authorities, has the disadvantage of giving no clue to the area where the language was spoken. Almost all the early manuscripts which are held to represent most accurately the language of the Slavonic apostles or that of their disciples show the phonetic features which we should expect in an earlier form of Bulgarian, more particularly in Macedonian Bulgarian.

The more important of these features are: (1) the Common Slav groups *tj* and *dj* appear as *št* and *žd* respectively, a development which exists in Bulgarian only; (2) the sound transcribed as *ě* (derived from I.E. *ē* or a diphthong ending in *i*) was a palatal *a* (probably like that in English "sand"), and it still occurs in the dialects of precisely that neighbourhood from which the brothers came; (3) the affricate *dz*, which in most Slavonic languages has become *z*, was characteristic of O.B. and is still found in Macedonian dialects.

We do not possess the actual translations made by Cyril and Methodius, but only copies, the earliest dating from the end of the 10th century, the work of those disciples who were engaged in spreading the Gospel in the Balkans. Although dialectical modifications betray the linguistic usage of the various scribes, modern research has been able to restore in great part the exact language of the brothers.

This ideal Old Bulgarian has preserved most of the archaic features of the Slavonic spoken a few hundred years earlier, before the differentiation into several languages had occurred. It offers, however, such characteristically south Slav features as: (1) the change of *or, ol* and *er, el* between consonants, to *ra, la* and *rě, lě* respectively; (2) the simplification of *tl* and *dl* to *l;* and (3) the change of *kv* and *gv* before front vowels (still preserved in the western group) to *cv* and *dzv*. The language is of the synthetic type and contains few foreign elements in its vocabulary. The Christian terminology is mainly Greek; the Latin words which occasionally occur are concessions to the Moravians and Pannonians, to whom they had become known through the proselytizing activity of the western clergy.

O.B. underwent in course of time considerable modifications, both phonetic and structural, in the various countries in which it had become the liturgical language, and the various manuscripts are consequently classified as Serbian-Slavonic, Croatian-Slavonic, Russian-Slavonic and Bulgarian-Slavonic, according to the different recensions.

The manuscripts are preserved in two alphabets. In the older (Glagolitic) alphabet we have:

1. The so-called Kiev leaves—a fragment of a missal—pub-

lished in Cyrillic transcription by Vatroslav Jagić, under the title of *Glagolitica: Würdigung neuentdeckter Fragmente* (Vienna, 1900). Linguistically and historically, this monument is of great importance and may go back to the end of the 10th century.

2. Codex Zographensis, published by Jagić under a Latin title (Berlin, 1879).

3. Codex Marianus. The edition by Jagić (Berlin, 1883) contains a full critical apparatus.

4. Codex Assemanianus, published in a Latin transcription by J. Crnčić (Rome, 1878).

5. Psalterium Sinaiticum, published by L. Geitler (Zagreb, 1883).

6. Euchologium Sinaiticum, published by Geitler (Zagreb, 1882).

7. Glagolitica Clozianus, published by V. Vondrák (Prague, 1893).

There are also a few other fragments.

The other monuments are written in the Cyrillic alphabet and are:

1. A short burial inscription, dated 993.

2. The Sava Gospel (*Savvina Kniga*), published by V. Ščepkin (St. Petersburg, 1903).

3. Codex Suprasliensis, published by Severjanov (St. Petersburg, 1904).

BIBLIOGRAPHY.—*Entstehungsgeschichte der kirchenslavischen Sprache*, by V. Jagić (Berlin, 1913), gives a mass of reliable miscellaneous information. The best grammars are: V. Vondrák, *Altkirchenslavische Grammatik* (Berlin, 1912); A. Leskien, *Grammatik der altbulgärischen (altkirchenslavischen) Sprache* (Heidelberg, 1909), which is more comparative and historical than his *Handbuch d. altb.* (*altk.*) *Sprache* (Heidelberg, 1922). There is also an excellent manual in Polish by J. Łoś (Lwów-Warszawa-Kraków, 1922) and a Czech translation (Prague, 1928), by B. Havránek, of S. Kul'bakin's manuscript grammar, which appeared in French as one of the publications of the Institut d'Études Slaves of Paris. Vondrák's *Kirchenslavische Chrestomathie* (Göttingen, 1910) is invaluable as a collection of extracts. The dictionary of F. Miklosich, *Lexicon palaeoslovenico-graeco-latinum emendatum auctum* (Vienna, 1862–65), has not been replaced, but it must be used with caution, as many words belonging to the later ecclesiastical language of the Slavs are quoted.

Bulgarian Language.—Out of Old Slavonic emerged the modern Bulgarian language. Most authorities hold that Bulgarian, together with Serbo-Croat and Slovene, belongs to the southern branch of the Slavonic languages, but its precise affinities are disputed. August Leskien, in his Serbian grammar (1914), while admitting certain special affinities with Serbo-Croat, regards it as an independent branch. Belić asserts that it belongs to the southern branch only because of its geographical position. The most noteworthy south Slav development which it shows is the change of Common Slavonic (C.S.) *or* and *ol*, either in initial position or between consonants, to *ra* and *la*, and a parallel transposition of consonant and vowel for *er* and *el;* but even this characteristic is not conclusive, as it is also partly shared by Czechoslovak, which belongs to the western branch. As to phonetics, we may note the following features of the literary language: C.S. *tj* and *dj* become *št* and *žd* respectively (a development found in no other modern Slav language); the nasal vowels *ǫ* and *ę* have become oral, the first having changed into a sound (roughly like that of the vowel in English *but*) which does not occur in any cognate language; the softening of consonants before front vowels has been, as also in Serbo-Croat, largely given up, nor have the old distinctions of quantity and intonation survived. In this last feature Bulgarian agrees with Russian, although the accented syllable often varies in the two languages, and is in marked contrast with Serbo-Croat, where length and intonation are preserved in almost all the dialects.

No less remarkable are the peculiarities in other domains of the grammar, the analytical character of which runs counter to the general trend of Slavonic and shows distinct points of resemblance to the development undergone by the languages of western Europe. Thus, whereas the cases are retained in every other Slav language and dialect, Bulgarian has discarded them almost as completely as the Romance languages and contents itself with a single case, the nominative, the others being expressed by means of prepositions. Bulgarian has a definite article and has lost the infinitive. Parallels are to be found in the other Balkan languages, both Rumanian and Greek, for example, having fewer cases than the classical languages from which they are descended: Rumanian and Albanian have a postpositive article, the uses of which largely agree with that of Bulgarian; lastly, the infinitive has entirely disappeared in Greek and has nearly gone both in Rumanian and Albanian.

This agreement with other Balkan languages has led many scholars to believe that Bulgarian has received the impress of a specifically Balkan type. This would seem incontrovertible if the modern language only were in question, but once we consider the earlier stages of the language we encounter difficulties. The language of the first translators of the Bible (*see* above), the ancestor of present-day Bulgarian, shows no trace whatever of "Balkanization." It has a complete case system, no articles and makes full use of the infinitive.

It is therefore best to regard modern Bulgarian as having undergone a development parallel with, but not dependent on, that of its neighbours. Some of the other Slav languages show in embryo the same tendencies which Bulgarian has so completely carried through. Serbian, the nearest neighbour of Bulgarian, has not only almost entirely abandoned the infinitive in the spoken language, but makes one case in the plural do duty for three (locative, dative and instrumental).

The dialects are numerous, chiefly distinguished by phonetic differences. The most usual division is into an eastern and a western group, according to how C.S. *ě* is pronounced. In the west, the sound—which in O.B. is thought to have been that of *a* in "sand," with palatalization of the preceding consonant—is *e*, as in Serbian, but in the east the old sound has been maintained before nonpalatal consonants. East Bulgarian is further divided into two zones, according to whether the articulated noun ends in *o* or *ъt*. In the main the modern literary language is based on the *ъt* dialects of east Bulgarian.

The Slav dialects spoken in Macedonia represent a transitional stage between Bulgarian and Serbo-Croat. None of them is used for literary purposes, but they have been carefully investigated in recent years, with a view to determining to what extent they have preserved characteristics of their lineal ancestor, the old ecclesiastical language (O.B.). A feature shared by many of them, but not occurring in O.B., is the development of C.S. *tj* and *dj* to fronted *k* and *g*, in place of literary Bulgarian *št* and *žd*.

In some Bulgarian dialects, notably those in the neighbourhood of Salonika and Castoria, there are distinct traces of the O.B. nasal vowels, which are not elsewhere preserved except in Polish and, also in traces, in some Slovene dialects.

In the vocabulary of modern Bulgarian there are many foreign elements, chiefly Turkish and Greek, but also some Rumanian and Albanian words. Russian supplied literary models, and its vocabulary has been very freely drawn upon, although there is now a tendency to restrict the loan words to expressions belonging to more abstract thought. The phraseology of Russian, French and German has had considerable influence on the sentence construction.

BIBLIOGRAPHY.—For the linguistic affinities of Bulgarian consult V. Vondrák, *Vergleichende Slavische Grammatik* (Göttingen, 1924), and B. Conev, *History of the Bulgarian Language* (in Bulgarian, Sofia, 1919). G. Weigand's *Balkan-Archiv* (Leipzig, 1925) also is valuable for the comparative study of the Balkan languages. *Das Ostbulgarische* by L. Miletič (Vienna, 1903) and A. Mazon's *Contes slaves de la Macédoine sud-occidentale* (Paris, 1923) are excellent introductions to the study of the dialects.

Dictionaries: N. Gerov, *Rečnik na blgarskyj jazyk* (*Dictionary of the Bulgarian Language*) 5 vol. (Philippopolis, 1895–1904); C. Stephanove, *Complete English-Bulgarian Dictionary* (Sofia, 1914), is the best work for English users. For those able to read Bulgarian the *Sbornik za narodni umotvorenija i narodopis,* published by the Bulgarian Academy, is the standard publication, and the *Bulgarska Reč*, a monthly linguistic periodical published at Sofia since 1921, will prove useful.

There are no scientific grammars, nor annotated and accented texts in English, but beginners able to read German will find G. Weigand's grammar and addition of *Baj Ganja* of great assistance. (N. B. J.)

OLD TESTAMENT: *see* BIBLE.

OLD TOWN, a city of Penobscot county, Me., U.S., on the Penobscot river, 12 mi. above Bangor. It is served by the Maine

Central railway. Pop. (1950) 8,261; (1940) 7,688 by the federal census. The city occupies Marsh Island, formed by a tributary of the Penobscot, which unites with it at two points 9 mi. apart, and considerable land on the west bank of the Penobscot. Opposite, on Indian Island, is the principal settlement of the Penobscot Indians, who are wards of the state.

The abbé Louis Pierre Thury was sent there from Quebec about 1687 and built a mission church. Permanent settlement began when John Marsh (about 1774) bought the "island" now occupied by the city. Old Town was incorporated as a town in 1840, and chartered as a city in 1891. The first railroad in Maine was built from Bangor to Old Town in 1836.

OLDYS, WILLIAM (1696–1761), English antiquary and bibliographer, natural son of William Oldys, chancellor of Lincoln, was born on July 14, 1696, probably in London.

His father had held the office of advocate of the admiralty but lost it in 1693 because he would not prosecute as traitors and pirates the sailors who had served against England under James II. William Oldys, the younger, lost part of his small patrimony in the South Sea Bubble (*q.v.*) and in 1724 went to Yorkshire, spending the greater part of the next six years as the guest of the earl of Malton.

He devoted most of his life to the collection of rare books and papers. In 1731 he sold his collections to Edward Harley, earl of Oxford, who appointed him his literary secretary in 1738. Three years later his patron died, and from that time he worked for the booksellers.

His habits were irregular, and in 1751 his debts drove him to the Fleet prison. After two years' imprisonment, he was released through the kindness of friends who paid his debts. In April 1755 he was appointed Norroy king-of-arms by the duke of Norfolk. He died on April 15, 1761.

William Oldys' chief works are: *The British Librarian,* a review of scarce and valuable books in print and in manuscript (1737–38); the *Harleian Miscellany* (1744–46), a collection of tracts and pamphlets in the earl of Oxford's library, undertaken in conjunction with Samuel Johnson; 22 articles contributed to the *Biographia Britannica* (1747–60); an edition of Raleigh's *History of the World,* with a *Life* of the author (1736); *Life of Charles Cotton* prefixed to Sir John Hawkins' edition (1760) of the *Compleat Angler.* In 1727 Oldys began to annotate another Langbaine to replace the one he had lost. This valuable book, with a manuscript collection of notes by Oldys on bibliographical subjects, is preserved in the British museum.

OLEACEAE, the olive family, dicotyledonous shrubs and trees of warm, temperate and tropical regions, especially abundant in the East Indies. *Fraxinus* includes the ash (*q.v.*) and flowering ash (*F. Ornus*). *Olea* includes the olive (*q.v.*) and the black ironwood tree (*O. laurifolia*). The family includes also numerous valuable ornamental trees and shrubs, as privet, jasmine, lilac, golden bells and fringe tree. There are 21 genera and about 500 species, approximately 40 of which occur in North America.

OLEAN, a city of Cattaraugus county, N.Y., U.S., on the Allegheny river, at the mouth of Olean creek, 70 mi. S.S.E. of Buffalo.

Olean is served by the Erie and the Pennsylvania railways. The population was 22,842 in 1950 by federal census, as compared with 21,506 in 1940 and 21,790 in 1930. The city lies in a valley 1,440 ft. above sea level, almost encircled by hills. The surrounding country is rich in oil and gas.

Six miles S.W. is "Rock City," a group of immense rocks, strangely regular in shape, covering 40 ac. At Allegany, a village 3 mi. W., is St. Bonaventure university (Roman Catholic; 1859). The city has railroad shops and an oil refinery and manufactures chrome tubular furniture, diesel engines, cutlery, floor and wall tile and various other products. Settlement in this region began in 1804.

Olean was incorporated in 1893.

OLEANDER, the common name for any shrub of the genus *Nerium.* The best known is *N. oleander,* often called rose bay, a native of the Mediterranean region, characterized by its tall shrubby habit and its thick lance-shaped opposite leaves, which exude a poisonous milky juice when punctured. The flowers are borne in terminal clusters, and are of a rose colour, rarely white. The hairy anthers adhere to the thickened stigma. The fruit or seed vessel consists of two long pods, which liberate a number of seeds, each of which has a tuft of silky hairs. The genus *Nerium* belongs to the family Apocynaceae (*q.v.*). The oleander was known to the Greeks under three names (viz., *rhododendron, nerion* and *rhododaphne*) and is well described by Pliny (xvi, 20), who mentions its roselike flowers and poisonous qualities. The oleander has long been cultivated in greenhouses, being, as John Gerard says, "a small shrub of a gallant shewe"; numerous varieties, differing in the colour of their flowers, which are often double, have been introduced. In warm countries it is widely grown outdoors.

OLEASTER (*Elaeagnus angustifolia,* family Elaeagnaceae), a handsome deciduous Eurasian tree, 15 to 20 ft. high, commonly cultivated for its edible fruit, often under the names of Trebizond date or Russian olive. The brown smooth branches are more or less spiny; the narrow leaves have a hoary look from the presence of a dense covering of star-shaped hairs; the small fragrant yellow flowers, which are borne in the axils of the leaves, are scaly on the outside.

OLEFIN, in organic chemistry, is the generic name given to an unsaturated hydrocarbon containing one or more pairs of doubly-linked carbon atoms. The unsaturation is represented by a double bond, C=C, which indicates the point of unsaturation and of reactivity in the molecule. The olefins are classified in either one, or in both, of the following ways: (1) A cyclic, or an acyclic, olefin is one in which the double bond is located between carbon atoms forming part of a cyclic, or of an open-chain, grouping respectively. (2) A mono-, di-, tri-, or polyolefin is one in which the number of double bonds per molecule is one, two, three, or an unspecified number greater than two, respectively.

The diolefins (or tri- or polyolefins) may be classified according to the relative positions of the double bonds as: (a) "cumulated" or "contiguous diolefins," or "allenes," containing the two double bonds adjacent to each other as in allene 1,2-propadiene ($CH_2=C=CH_2$); (b) "conjugated diolefins," in which the double bonds are separated by one single linkage as in 1,3-butadiene ($CH_2=CH-CH=CH_2$); (c) "isolated diolefins," in which the double bonds are separated by at least two single linkages as in 1, 4-pentadiene ($CH_2=CH-CH_2-CH=CH_2$).

The terms aliphatic, aryl, cyclic, etc., are used to indicate the form of the carbon skeleton. The terminations -ene, -diene, -triene, etc., in the systematic Geneva system of nomenclature, identify the individual hydrocarbons of mono-, di- or triolefinic structure. Sometimes the ending -ylene is given to identify a monoolefin, *e.g.,* ethylene, propylene, etc. The position of the double bonds is indicated by a numerical prefix or suffix.

Olefins containing from two to four carbon atoms per molecule are gaseous at ordinary temperatures and pressures; those containing five or more carbon atoms are usually liquid at ordinary temperatures. They are only slightly soluble in water. The physical constants of some aliphatic olefins are given in the following table. In general, the boiling points are very close to those of the saturated hydrocarbons having the same carbon skeleton; the densities are slightly higher.

Name	Formula	Melting Point °C.	Boiling Point °C.	Density d_4^{20}
Ethylene	$CH_2=CH_2$	−169.4	−103.9	
Propene	$CH_3-CH=CH_2$	−185.2	−47.6	
1-Butene	$CH_3-CH_2-CH=CH_2$	−190	−6.3	
1-Pentene	$CH_3-(CH_2)_2-CH=CH_2$	−138.0	30.1	0.6410
1-Hexene	$CH_3-(CH_2)_3-CH=CH_2$	−141.0	63.7	0.6734
1-Heptene	$CH_3-(CH_2)_4-CH=CH_2$	−120.0	92.8	0.6968
1-Octene	$CH_3-(CH_2)_5-CH=CH_2$	−102.1	121.6	0.7150
1-Nonene	$CH_3-(CH_2)_6-CH=CH_2$	−88.0	145	0.7315

Monoolefins (aliphatic) have the general formula C_nH_{2n}; they are not found in nature. They are formed in large quantities during the cracking of petroleum oils to produce gasoline. The olefins thus obtained are mixed with other types of hydro-

carbon, from which they are separated either by physical or by chemical means.

Pure olefins may be prepared by the dehydration of the corresponding alcohols. Lower olefins, C_2 to C_5 can be prepared by the catalytic dehydrogenation of the corresponding paraffins.

The principal reactions of olefins are those of the addition of various elements or groups to the two doubly-linked carbon atoms. Hydrogen reacts with olefins, under the influence of catalysts such as platinum black or finely divided nickel, to form the corresponding paraffins.

$$CH_3-C(CH_3)_2-CH_2-C(CH_3)=CH_2 + H_2 \xrightarrow{Ni} CH_3-C(CH_3)_2-CH_2-CH(CH_3)-CH_3$$

2,4,4-Trimethylpentene — 2,2,4-Trimethylpentane "isooctane"

Halogens such as chlorine, bromine and iodine add to the doubly-linked carbon atoms to yield dihaloparaffins.

$$CH_3-CH=CH-CH_3 + Cl_2 \longrightarrow CH_3-CHCl-CHCl-CH_3$$

Butene-2 — 2,3-Dichlorobutane

Hydrogen halides on reaction form monohaloparaffins (alkyl halides).

$$CH_3-C(CH_3)=CH-CH_3 + HBr \longrightarrow CH_3-CBr(CH_3)-CH_2-CH_3$$

2-Methyl-2-butene — 2-Methyl-2-bromobutane

Hypochlorous or hypobromous acids combine with olefins to produce the corresponding halohydrins.

$$CH_2=CH_2 + HOCl \longrightarrow CH_2Cl-CH_2OH$$

Ethylene — Ethylene chlorohydrin

Water reacts with olefins in the presence of catalysts such as sulphuric acid to form alcohols.

$$CH_3-CH=CH_2 + H_2O \xrightarrow[H_2SO_4]{dilute} CH_3-CH(OH)-CH_3$$

Propene — Isopropyl alcohol

Oxidation of olefins with dilute potassium permanganate results in the addition of two hydroxyl groups at the point of unsaturation to form glycols. Under the influence of stronger oxidizing agents or more drastic conditions, the double bond is ruptured and oxygen-containing compounds, such as acids or ketones, are obtained.

$$CH_3-C(CH_3)=CH-CH_3 \xrightarrow[agent]{oxidizing} CH_3COCH_3 + CH_3COOH$$

2-Methyl-2-butene — Acetone — Acetic acid

Ozone reacts with olefins in solution to form an ozonide, which, when isolated in pure form, is explosive; by treatment of the ozonide with water, the originally unsaturated carbon-carbon linkage is ruptured with the formation of aldehydes and ketones.

$$CH_3-C(CH_3)=CH-CH_3 + O_3 \longrightarrow CH_3-C(CH_3)(-O-)-O-CH(-O-)-CH_3$$

2-Methyl-2-butene — Ozonide

$$CH_3-C(CH_3)(-O-)-O-CH(-O-)-CH_3 + H_2O \longrightarrow CH_3-CO-CH_3 + CH_3-CHO + H_2O_2$$

Acetone — Acetaldehyde

This reaction is employed, in particular, for the determination of the structures of olefins.

In the presence of certain catalysts, two or more molecules of olefin combine to form polymers.

$$CH_3-C(CH_3)=CH_2 + CH_3-C(CH_3)=CH_2 \xrightarrow{H_3PO_4} CH_3-C(CH_3)_2-CH_2-C(CH_3)=CH_2$$

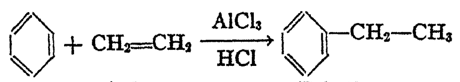
Isobutylene — Isobutylene — 2,4,4-Trimethylpentene "diisobutylene"

The proper choice of catalysts and reaction conditions makes possible the formation of valuable products with specific properties.

Olefins react in the presence of catalysts with organic compounds such as isoparaffins, aromatic hydrocarbons and phenols to form additional products of great industrial importance, which are used in the manufacture of aviation gasoline, synthetic rubber, detergents and plastics.

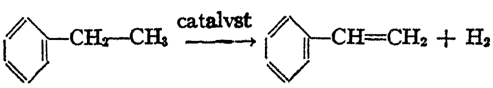
Ethylene (ethene) $CH_2=CH_2$ is the first member of the olefin series. It is one of the dominant raw materials in organic chemical industry. A large proportion is converted into industrial ethyl alcohol and derivatives thereof.

The following are some of the commercial products obtained from ethylene: ethylene glycol (CH_2OH-CH_2OH) is produced via ethylene oxide (CH_2-CH_2, bridged by O) by selective oxidation of ethylene. Polythene, a plastic obtained from ethylene at elevated pressures and temperatures in the presence of a minor amount of oxygen. On account of its high dielectric constant and chemical inactivity it is used for electric appliances. Ethylbenzene is a product of interaction of ethylene and benzene;



Benzene — Ethylene — Ethylbenzene

on dehydrogenation, it forms styrene,



Styrene

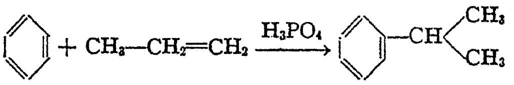
one of the important starting materials for both synthetic rubber and various plastics. Ethylene is an important starting material for the production of poisonous gases such as mustard gas.

$$CH_2=CH_2 + S_2Cl_2 \longrightarrow S(CH_2-CH_2Cl)_2 + S$$

Ethylene — Mustard gas

Ethylene is also used as a general anaesthetic and as an agent to hasten the ripening of bananas, citrous fruits, bulbs and potatoes.

Propene (propylene) $CH_3-CH=CH_2$ is used for the synthesis of isopropyl alcohol ($CH_3-CHOH-CH_3$), which on dehydrogenation, forms acetone ($CH_3-CO-CH_3$), one of the more important solvents. During World War II, a large amount of propene was made to react with benzene to form cumene,



Benzene — Propene — Cumene (Isopropylbenzene)

an important constituent of aviation gasoline.

Butene (butylene) is used for the synthesis of butyl alcohols (C_4H_9OH) and for the production of aviation gasoline. *n*-Butylenes are dehydrogenated to form butadiene.

$$CH_3-CH_2-CH=CH_2 \xrightarrow{catalyst} CH_2=CH-CH=CH_2 + H_2$$

1-Butene — 1,3-Butadiene

Olefins containing eight or more carbon atoms are useful for the synthesis of detergents and wetting agents. The sources of the normal chain olefins are animal and vegetable waxes and oils. These are converted into alcohols, from which the corre-

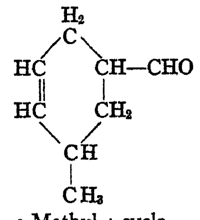
sponding olefins are obtained.

Diolefins (C_nH_{2n-2}) (dienes, alkadienes) containing conjugated double bonds are the most useful members of this series; they undergo reactions similar to those of monoolefins. When the addition reaction to conjugated diolefins is carried out stepwise, the addenda are often attached to the first and fourth carbon atoms of the conjugated system rather than to adjacent carbon atoms; such a reaction is called 1,4-addition.

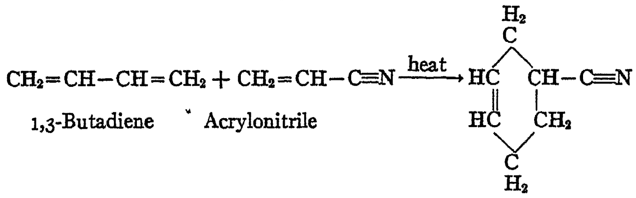
$$\underset{\text{1,3-Butadiene}}{CH_2=CH-CH=CH_2}+Br_2 \longrightarrow \underset{\text{1,4-Dibromo-2-butene}}{BrCH_2-CH=CH-CH_2Br}$$

The conjugated dienes react with compounds containing the $>C=C<$ (particularly $>C=C-C=O$, $>C=C-C\equiv N$, etc.) group with the formation of cyclic compounds.

$$\underset{\text{1,3-Pentadiene}}{CH_3-CH=CH-CH=CH_2} + \underset{\text{Acrolein}}{CH_2=CH-CHO} \xrightarrow{\text{heat}}$$



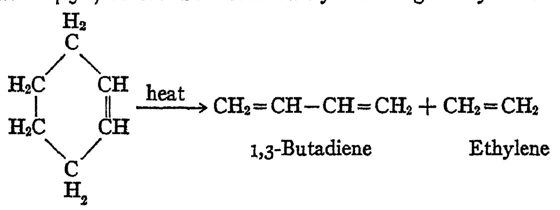
3-Methyl-4-cyclohexenylformaldehyde



1,3-Butadiene Acrylonitrile

3-Cyclohexenylcyanide

1,3-Butadiene ($CH_2 = CH - CH = CH_2$) melts at −108.7°, boils at −4.5°; it can be obtained by cracking of cyclohexene,



1,3-Butadiene Ethylene

Cyclohexene

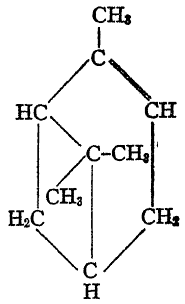
by dehydration of 1,3-butylene glycol,

$$\underset{\text{1,3-Butylene glycol}}{HOCH_2-CH_2-CHOH-CH_3} \xrightarrow{Al_2O_3} \underset{\text{1,3-Butadiene}}{CH_2=CH-CH=CH_2} + 2H_2O$$

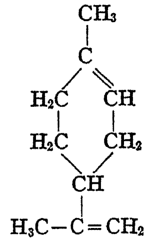
or by catalytic treatment of ethyl alcohol; it is prepared commercially by dehydrogenation of normal butylenes. Butadiene is the main starting material for the manufacture of synthetic rubber.

Isoprene (2-Methyl-1,3-butadiene) ($CH_2=\underset{\substack{|\\CH_3}}{C}-CH=CH_2$) melts at −146.8°, boils at 34.1°, d_4^{20} 0.6805. It is a building unit for naturally occurring products such as rubber and terpenes; these products, on pyrolysis, yield isoprene. Isoprene changes into rubberlike compounds when heated under pressure, or when treated with sodium or peroxides.

Cyclic Olefins.—Of the cyclic olefins, those belonging to the class of terpenes $C_{10}H_{16}$ are the most abundant in nature. They are divided into (a) bicyclic monoolefins (bicyclic terpenes) of which pinene,



the main constituent of turpentine oil, is the most important representative. Pinene is used for the synthesis of camphor, resins and plastics; (b) monocyclic diolefins (monocyclic terpenes) of which limonene



is one of the most widely distributed terpenes, is present in the oil obtained from the skin of the fruits of the citrous species. It is used as a solvent and as a raw material for the synthesis of perfumes. (H. Ps.)

OLEIC ACID: *see* OILS, FATS AND WAXES.

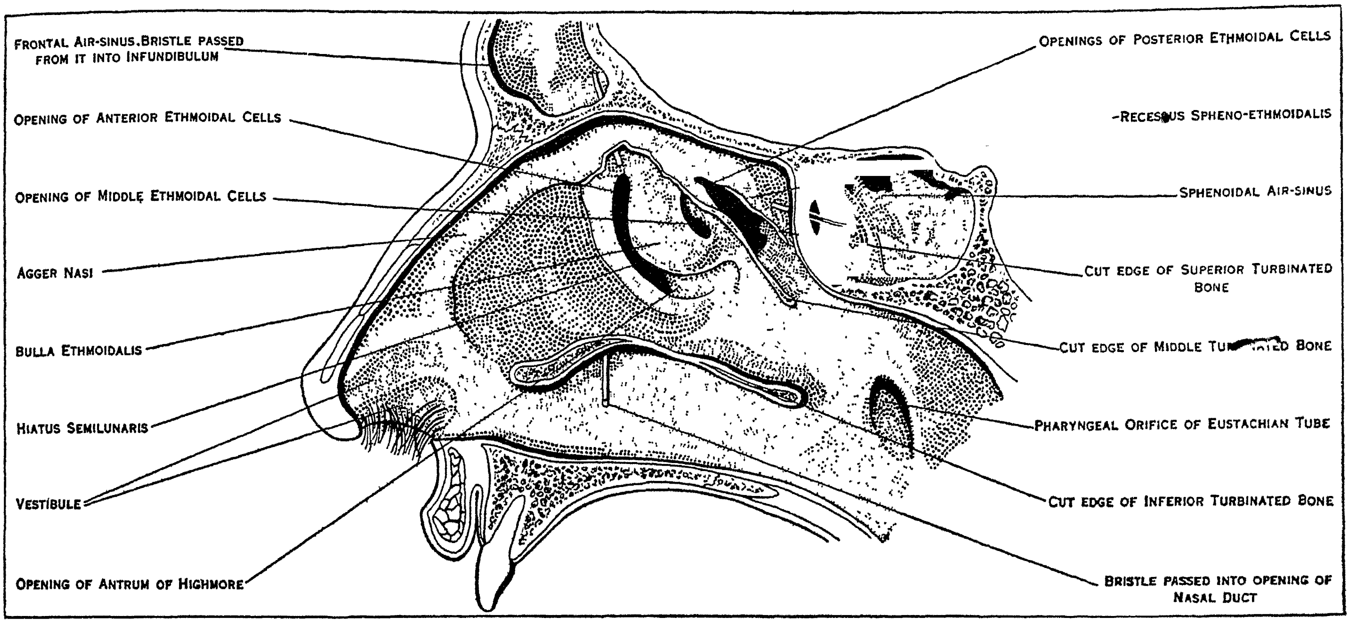
OLEN, a legendary poet and prophet, reputed author of certain hymns to Apollo, sung at Delos in historical times (Gr. Ὠλήν). Boio, a Delphic poetess, made him a Hyperborean (*see* HYPERBOREANS), founder of the oracular shrine at Delphi, first prophet there and inventor of the hexameter. Herodotus makes him a Lycian (as follower of Apollo Λύκειος). Whether any real person lies behind these stories is unknown.

OLEOMARGARINE: *see* MARGARINE.

OLÉRON, an island lying off the west coast of France, opposite the mouths of the Charente and Seudre, and included in the department of Charente-Maritime. Pop. (1946) 12,820. Oléron, the Uliarus Insula of Pliny, formed part of the duchy of Aquitaine, and came into the possession of the French crown in 1370. It is about 18 mi. in length from northwest to southeast, and 7 mi. in extreme breadth; area 66 sq.mi.; the strait (Pertuis de Maumusson) separating it from the mainland is at one point less than a mile wide. The chief places are St. Pierre (pop. 3,550 in 1946), the Château d'Oléron (1,363) and the watering place of St. Trojan-les-Bains (934).

OLFACTORY SYSTEM. In anatomy, the olfactory system consists of the nose and the nasal cavities, which support the olfactory mucous membrane for the perception of smell in their upper parts, and act as respiratory passages below.

The bony framework of the nose is part of the skull (*q.v.*), but the outer nose is supported only by bone above; lower down its shape is kept by cartilaginous plates. The expanded lower part of the side of the nose, the "ala," is formed only of skin, both externally and internally, with fibro-fatty tissue between the layers. The nasal cavities are separated by a septum covered in its lower two-thirds by thick, highly vascular mucous membrane composed of columnar ciliated epithelium with masses of acinous glands embedded in it, while in its upper part it is covered by the less vascular but more specialized olfactory membrane. Near the front of the lower part of the septum a slight opening into a short blind tube, which runs upward and backward, may sometimes be found; this is the vestigial remnant of "Jacobson's organ." The supporting framework of the septum is made up of ethmoid above, vomer below and the septal cartilage in front. The outer wall of each nasal cavity is divided into three meatuses by the overhanging turbinated bones (*see* fig. 2). Above the superior turbinated bone is a space between it and the roof known as the recessus spheno-ethmoidalis, into the back of which the



FROM R. HOWDEN, IN "CUNNINGHAM'S TEXT BOOK OF ANATOMY" (OXFORD MEDICAL PUBLICATIONS)

FIG. 1.—VIEW OF THE OUTER WALL OF THE NOSE, THE TURBINATED BONES HAVING BEEN REMOVED

sphenoidal air sinus opens. Between the superior and middle turbinated bones is the superior meatus, containing the openings of the posterior ethmoidal air cells, while between the middle and inferior turbinated bones is the middle meatus, which is the largest of the three and contains a rounded elevation, the bulla ethmoidalis. Above and behind this is often an opening for the middle ethmoidal cells; below and in front runs a deep sickle-shaped gutter, the hiatus semilunaris, which communicates above with the frontal air sinus and below with the opening into the antrum of Highmore or maxillary antrum. The inferior meatus is below the inferior turbinated bone, and, when that is lifted, the valvular opening of the nasal duct (*see* EYE, HUMAN) is seen. The roof of the nose is narrow, and here the olfactory nerves pass in through the cribriform plate. The floor is wider so that a coronal section through each nasal cavity has roughly the appearance of a right-angled triangle.

Embryology.—In the third week of intrauterine life two nasal pits appear on the under side of the front of the head; they are the first appearance of the true olfactory region of the nose, and some of their epithelial lining cells send off axons (*see* NERVOUS SYSTEM) which arborize with the dendrites of the cells of the olfactory lobe of the brain and so form the olfactory nerves. Between the olfactory pits the broad median frontonasal process grows down from the forehead region to form the dorsum of the nose (*see* fig. 2) and the anterior part of the nasal septum, while outside them the lateral nasal processes grow down and later on meet the maxillary processes from the first visceral arch. In this way the nasal cavities are formed, but are separated from the mouth by a thin bucconasal membrane which eventually is broken through; after this the mouth and nose are one cavity until the formation of the palate in the third month (*see* MOUTH AND SALIVARY GLANDS). In the third month Jacobson's organ may be seen as a well-marked tube lined with respiratory mucous membrane; no explanation of the function of Jacobson's organ in man is known, and it is probably entirely atavistic. At birth the nasal cavities are shallow from above downward, but rapidly deepen till the age of puberty.

Comparative Anatomy.—In Amphioxus among the Acrania there is a ciliated pit above the anterior end of the central nervous system, which is probably a rudiment of an unpaired olfactory organ. In the Cyclostomata (lampreys and hags) the pit is at first ventral, but later becomes dorsal and shares a common opening with the pituitary invagination. It furthermore becomes divided internally into two lateral halves. In fishes there are also two lateral pits, the nostrils of which open sometimes, as in the elasmobranchs (sharks and rays), onto the ventral surface of the snout, and sometimes, as in the higher fishes, onto the dorsal surface. Up to this stage the olfactory organs are mere pits, but in the Dipnoi (mudfish) an opening is established from them into the front of the roof of the mouth, and so they serve as respiratory passages and organs for the sense of smell. In the higher Amphibia the nasal organ becomes included in the skull and respiratory and olfactory parts are distinguished. In this class, too, turbinal ingrowths are found, and the nasolachrymal duct appears.

In the lizards, among the Reptilia, the olfactory and respiratory parts are very distinct, the latter being lined only by stratified epithelium unconnected with the olfactory nerves. There is one true turbinal bone growing from the outer wall, and close to this is a large nasal gland. In crocodiles the hard palate is formed, and there is henceforward a considerable distance between the openings of the external and internal nares. In this order, too (Crocodilia), air sinuses are first found extending from the olfactory cavities into the skull bones.

The birds' arrangement is very like that of the reptiles; olfactory and respiratory chambers are present, and into the latter projects the true turbinal, though there is a pseudoturbinal in the upper or olfactory chamber. In mammals the olfactory chamber of the nose is variously developed; most of them are "macrosmatic," and have a large area of olfactory mucous membrane; some, like the seals, whalebone whales, monkeys and man, are "microsmatic," while the toothed whales have the olfactory region practically suppressed in the adult, and are said to be "anosmatic." There are generally five turbinal bones in macrosmatic mammals, so that man has a reduced number. The lowest of the series or "maxilloturbinal" is the equivalent of the single true turbinal bone of birds and reptiles, and in most mammals is a double scroll, one leaf turning upward and the other down.

Jacobson's organ first appears in amphibians, where it is found as an anteroposterior gutter in the floor of the nasal cavity. In reptiles the roof of the gutter closes in on each side, and a tube is formed lying below and internal to the nasal cavity, opening anteriorly into the mouth and ending by a blind extremity, posteriorly to which branches of the olfactory and trigeminal nerves are distributed. In the higher reptiles (crocodiles and chelonians) the organ is suppressed in the adult, and the same applies to birds; but in the lower mammals, especially the monotremes, it is very well developed, and is enclosed in a cartilaginous sheath, from which a turbinal process projects into its interior. In other mammals, with the exception of the Primates and perhaps the Chiroptera, the organ is quite distinct, though even in man, as has been shown, its presence can be demonstrated in the embryo.

OLGA, wife of Igor, prince of Kiev, and afterward (from 945) regent for Sviatoslav her son, was baptized at Constantinople about 955 and died about 969. She was canonized in the Russian church; her feast is on July 11.

OLGIERD (d. 1377), grand duke of Lithuania, was one of the seven sons of Gedymin, grand duke of Lithuania, among whom on his death in 1341 he divided his domains, leaving the youngest, Yavnuty, in possession of the capital, Vilnius, with a nominal priority. With the aid of his brother Kiejstut, Olgierd in 1345 drove out the incapable Yavnuty and declared himself grand duke. His reign (1345–77) saw the development and extension of Lithuania to one of the greatest states in Europe of that time. The Teutonic knights in the north and the Tatar hordes in the south were equally bent on the subjection of Lithuania, while Olgierd's eastern and western neighbours, Muscovy and Poland, were far more frequently hostile competitors than serviceable allies. Olgierd not only held his own, but acquired influence and territory at the expense of both Muscovy and the Tatars, and extended the borders of Lithuania to the shores of the Black sea. He desired to establish the Lithuanian power in those Russian lands which had formed part of the ancient grand duchy of Kiev. He procured the election of his son Andrew as prince of Pskov, and a powerful minority of the citizens of the republic of Novgorod held the balance in his favour against the Muscovite influence, but his ascendancy in both these commercial centres was precarious. However, he acquired the principalities of Smolensk and Bryansk in central Russia. His relations with the grand dukes of Muscovy were friendly, and twice he married orthodox Russian princesses; nevertheless, he besieged Moscow in 1368 and again in 1372, both times unsuccessfully.

Olgierd won a great victory over the Tatars at Siniya Vodui on the Bug in 1362, which practically broke up the great Kipchak horde and compelled the khan to migrate farther south and make his headquarters for the future in the Crimea. Indeed, but for the unceasing simultaneous struggle with the Teutonic knights, the burden of which was heroically borne by Kiejstut, Russian historians frankly admit that Lithuania, not Muscovy, must have become the dominant power of eastern Europe. Olgierd died in 1377, accepting both Christianity and the tonsure shortly before his death. His son Jagiello ultimately ascended the Polish throne, and founded the dynasty which ruled Poland nearly 200 years.

OLIGARCHY is the traditional term used to denote the rule of the few when that rule is looked upon with disfavour. Aristotle used it to designate the rule of the few when it was exercised not by the best, but by bad men unjustly. In this sense, it overlaps with the later concept of plutocracy.

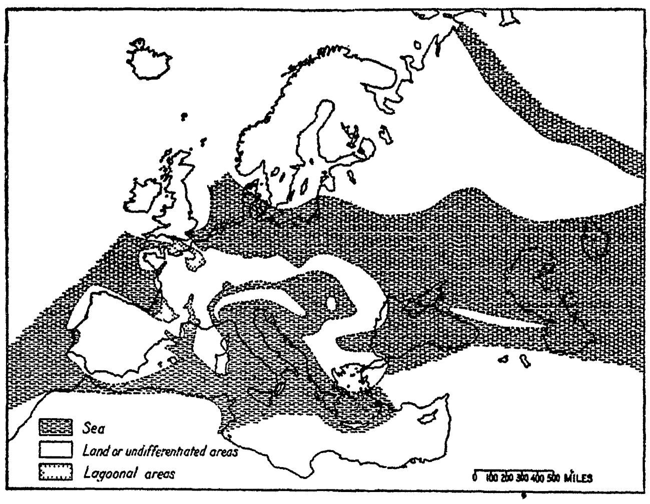
It is a recurrent idea that all forms of government are in the final analysis reducible to the rule of a few. Oligarchs will secure effective control whether the formal authority is vested in the people, a monarch, the proletariat or a dictator. Thus, Karl Marx and Friedrich Engels insisted that throughout capitalism, the key capitalists had controlled the government; they coined the famous phrase that "the state is the executive committee of the exploiting class." The Italian political scientist Gaetano Mosca likewise insisted that a "ruling class" always constituted the effective oligarchical control. Vilfredo Pareto elaborated the idea in his doctrine of the "elite." The modern tendency to analyze social patterns in terms of an "elite," although greatly reinforced by Pareto's theory, goes further back than Marx and Engels, who employed the term "elite" to describe the class-conscious communists, the leading group within the proletariat.

To say that all governments are in essence oligarchical may be an exaggeration. Yet a tendency persists in all organizations to evolve a limited group at the centre who, as insiders, "run the show." Political science and sociology are beginning to differentiate more carefully between various types of control and power. The type of power held by a democratic party boss, while overwhelming in relation to any single member of the party, is very different from that wielded by the boss of the single party in a totalitarian and authoritarian pattern. Likewise, the control group within an organization does not occupy the same position under democratic conditions (which provide for the group's being effectively challenged by outsiders at any time) as it does under an authoritarian plan. If effective control changes hands as rapidly as it does in a city of the U.S. or a British trade union, it is doubtful that those exercising it should be spoken of as a "class" or an "elite." The expression "the few" is too abstract to tell us much. Like the other purely numerical concepts of government inherited from Greek philosophy, oligarchy is an outmoded term, because it fails to direct attention to what we really wish to know about a government. (C. J. FR.)

OLIGOCENE (Gr. ὀλίγος, few, and καινός, recent), in geology the name given to the third series of the Tertiary system.

The Oligocene series thus includes those strata which occur above the Eocene and below the Miocene. These rocks were originally classed by Sir Charles Lyell as Older Miocene, the term Oligocene being proposed by H. E. Beyrich in 1854 and again in 1858. The Oligocene is thus the upper division of the older Tertiary system or Palaeogene. (*See* EOCENE; TERTIARY.)

Conditions during the Oligocene.—The Oligocene deposits are of fresh-water, brackish, marine and terrestrial origin; they include sands, sandstones, grits, marls, shales, limestones, conglomerates, lignites and volcanic materials. Here and there in Europe the sea gained ground that had been unoccupied by Eocene waters, but important changes were in progress, and a general relative uplifting took place which caused much of the Eocene sea floor to be occupied at this time by lake basins and lagoons. Thus, there is a general tendency for marine Oligocene deposits to occupy a more restricted area than the marine Eocene. Among the earliest of the Tertiary mountain chains to arise were the Pyrenees and the mountains of Provence (the Alpine chain, properly speaking), which were already in existence at the end of the Eocene. Thus, relatively unfolded Oligocene sediments are found on the flanks of belts of folded Eocene strata. In some areas the folding of the margins of Eocene gulfs resulted in the deepening of the centre of the trough and permitted huge thicknesses of Oligocene to be deposited. This, for example, is the case in the Burmese gulf and on the Pacific coast of North America and northern border of South America where Oligocene sediments reach a thickness of more than 10,000 ft. As in the Eocene epoch, minor oscillations of level gave rise to cycles of sedimentation Perhaps the most striking change from



MAP OF EUROPE DURING THE OLIGOCENE EPOCH

Eocene topography in Europe, shown on the accompanying map, is the extension of the Oligocene sea over north Germany, whence it extended eastward through Poland and Russia to the Aral-Caspian region, communicating thence with arctic waters by way of a Ural depression. It was later in the epoch when the widespread emersion set in.

Life of the Epoch.—In its general features the life of the epoch resembled that of the Eocene (*q.v.*); foraminifera were abundant; nummulites were still numerous but of smaller size and are characteristically associated with lepidocyclines. Corals and bryozoa were abundant in the clear waters of southern seas but echnoids were rather less numerous. Cephalopods were still fewer but gastropods and pelecypods assumed more and more their present importance, and the genera were those already noted in the Eocene. Among vertebrates, rays and dogfish were the dominant marine fish; tortoises were abundant and the genus *Rana* made its appearance. The most interesting feature of the land fauna is the great variety of mammals, especially from the interior of North America and the continental Oligocene of Europe, Asia and South America. The mammals are important fossils for distinguishing subdivisions of the epoch. While many of the mammals were of mixed types, others are clearly representatives of modern groups and forerunners of existing genera. Thus, it is possible to distinguish carnivores (Canidae and Felidae), insectivores, rodents, ruminants and camels. Forerunners of the rhinoceros, elephant and horse are all clearly separable. For an account of the flora *see* PALAEOBOTANY OR PLANT PALAEONTOLOGY. The abundance of *Chara* associated with such molluscan genera as *Limnaea* and *Planorbis* in fresh-water deposits is especially noteworthy.

Oligocene Stratigraphy.—Neither the lower nor the upper limit of the Oligocene is well defined. As mentioned in the article on the Eocene (*q.v.*), the lower limit is usually taken as the top of the Bartonian stage (including the Ludian). The Aquitanian stage is classed sometimes with the Oligocene, sometimes with the Miocene. The first opinion is adopted by those who pay first attention to the mammalian faunas; the Aquitanian fauna is an impoverished representative of preceding faunas and is not marked by the appearance of new forms. On the other hand, the Aquitanian deposits seem to mark the feeble beginning of the Miocene transgression.

The type areas for Oligocene stratigraphy lie mainly in France, Belgium and Germany, among the lagoons left by the retreat of the Eocene seas. The following is the classification of the Oligocene which has been generally adopted (reading downward):

Marine stages Europe	Western North America	Eastern North America
Chattian (Casselian)	Lower Blakeley	Flint River
Rupelian	Lincoln	Byram limestone Marianna limestone
Tongrian (Lattorfian)	Upper Keasey	Forest Hill sand and Red Bluff clay

Tongrian Stage (Tongern, Belgium) is represented by marine and fresh water clays and sands in Belgium, marine sandy glauconitic beds in northern Germany at Latdorf between Magdeburg and Leipzig, and the famous series of supragypsiferous marls of the Paris basin. These sediments change in character from place to place and in the Paris basin were called the Sannoisian stage. Here at the base are blue marls, laid down in salt lagoons, then white marls with fresh-water horizons and finally green marine marls having a wide geographic distribution. Marine sands and clays deposited contemporaneously in northern Germany were called Lattorfian. In Britain, classic exposures of Lower Oligocene sediments of fresh, brackish and marine origin occur in the cliffs of the Isle of Wight and have been described from base upward as Middle Headon beds (brackish and marine), Upper Headon beds (fresh-water clays, marls and limestones) and Osborne and Bembridge beds (brackish and fresh-water sands, clays and limestones).

The exact correlation of the different members of the Tongrian stage in western Europe is still uncertain. Many geologists have considered the molluscan and echinoid faunas in these beds as closely allied biologically to those of the uppermost Eocene of the Paris basin.

Rupelian Stage (Rupel, a tributary of the Scheldt, in Belgium) is the most widely distributed and easily recognized geologic unit of the Oligocene in western Europe. It is represented in Belgium by a thick series of clays—the Argiles de Boom, in the Paris basin by the Sables de Fontainebleau and the underlying Brie limestone which formerly were referred to by the stage term Stampian. Marine sandstones of equivalent age, called the Septarien-ton, occur in the Mainz basin and in northern Germany, where they were deposited in a rapidly transgressing sea. The Hampstead beds in the Isle of Wight, which consist of marine brackish-water clays and marls, were deposited during early Rupelian time.

Chattian Stage (Chattes, an ancient tribe which lived near Cassel, Germany) is best represented in the Mainz basin and northern Germany by basal glauconitic marine sands and overlying brackish and fresh-water marls and limestones. Equiva-

lent beds are unknown in Britain and Belgium. After the deposition of the Fontainebleau sands, the sea left the Paris basin and its area was occupied by a huge lake within which accumulated the Étampes limestone of which the Meulière de Montmorency is a lateral equivalent. Above these beds lie the fresh-water Beauce limestones, which in part belong to the Aquitanian stage. Continental Oligocene beds are found in several basins of the central European continent.

Marine and continental Oligocene deposits occur in the Alpine geosyncline in southern and eastern Europe, in North Africa, southern Russia, the Aral-Caspian region, Iran and India and in places on the eastern border of Asia.

An exact correlation of the marine Oligocene deposits of North America and the Caribbean region with those of western Europe is difficult because of the provincial nature of the faunas in the western hemisphere. Marine sediments occur in the Gulf and Atlantic coastal plains of the United States, in eastern Mexico, Central America, West Indies, the northern third of Venezuela and Colombia and in western Ecuador and northwestern Peru. Thick deposits occur in the Coast ranges of California, Oregon and Washington and in southern Alaska and northeastern Asia.

Lower Oligocene sediments in the eastern United States occur only in Mississippi and Alabama and are represented by less than 100 ft. of the Forest Hill sand and the Red Bluff clay which accumulated as delta deposits. Resting on these are light-coloured shaly marls and clays of the Vicksburg group. These are known locally as the Marianna limestone, the Byram limestone and in Texas as the Frio clay. They were deposited during the Middle Oligocene in a more widely transgressing sea which extended at times from South Carolina westward into the Gulf coastal plain of Mexico. A slight subsidence of the coastal sea floor during Late Oligocene time was followed by the deposition of nearly 100 ft. of the Flint River and Suwanee limestones from South Carolina to northern Florida and by marls and shales of the Chickasaw from Alabama to the Mississippi river. No sediments of uppermost Oligocene (Upper Chattian) are exposed unless the sandstones of the lower part of the Catahoula formation extend down into the Oligocene. This formation is thought to have been deposited during the Aquitanian stage of the Lower Miocene. Marine limestones and shales of Oligocene age are widely distributed in the West Indies, Costa Rica and Panamá.

Marine Oligocene sediments which vary greatly in lithology and thickness are exposed in the northern part of Venezuela and Colombia. They are composed mainly of blue, brown and gray shales, interbedded sandy shales and sandstones and thick deposits of massive sandstone which were deposited in a slowly subsiding trough. These deposits range from 5,000 ft. to 10,000 ft. thick and have been described as the Mugrosa series, Colorado series and Poso series in Colombia and the El Fausto, Icotea, Churuguara, San Luis, Agua Clara, Agua Salada and Carapita formations in Venezuela. The Agua Clara formation is best known and consists of more than 800 m. of lagoonal gypsiferous shales with marine intercalations.

Several thousand feet of marine sandstones and shales occur in the coastal part of northwest Peru and extend northward through western Ecuador to Colombia. They accumulated in a north and south trough which at times had connections with the Pacific ocean. The marine faunas are related to those of the Caribbean region. Marine Oligocene deposits are almost entirely absent from the interior of South America.

During the Oligocene an area more than 100 mi. wide in western North America, extending from Vancouver Island to Lower California, was occupied from time to time by embayments of the Pacific ocean. These downfolds in the crust were formed at an earlier time by folding and faulting. In Oregon and Washington more than 10,000 ft. of marine shale, sandstone and conglomerate which accumulated in these basins have been classified from top downward as the Blakeley, Lincoln and Keasey formations. Faunal zones based on molluscs and foraminifera have been recognized within these deposits but it is uncertain how much of the Keasey formation extends down into the Eocene and how much of the upper part of the Blakeley formation ranges into the Miocene. In central California the Oligocene is represented by marine sandstones, sandy shales and deposits of volcanic tuff. Farther south in the Coast ranges occur thick deposits of massive and stratified light-gray shale called the Kreyenhagen formation. Zones based on foraminifera were established in these sediments indicating a time range from Upper Eocene, through Oligocene, into Lower Miocene. Stratigraphic sections of this formation vary greatly in age from place to place. Other basins in southern California were above sea level during the Oligocene and received thick accumulations of conglomerate, sandstone and shale which were named the Sespe formation. In certain places this formation ranges in age from Upper Eocene to Lower Miocene.

Sandstones and shales containing marine fossils similar to those of the Blakeley formation occur in southern Alaska, Sakhalin Island and the Kamchatka peninsula of Siberia. Several genera with eastern Asiatic ancestry were introduced into western North America during the Oligocene.

Land-laid deposits of Oligocene age occur in eastern Colorado, Nebraska, eastern Wyoming, North and South Dakota, Montana, Oregon, Nevada and California. In the eastern Rocky mountain area they are represented by the Wind River series, in Montana by the Pipestone Springs and Cook Ranch formations and in Oregon by the Lower John Day formation. The Sespe formation already referred to is best known in California. (C. E. We.)

OLIGOCHAETA, a class of the Annelida (*q.v.*), comprising the earthworms (*q.v.*), the enchytraeids and several families of small mud-living or aquatic, rarely marine or parasitic, species.

OLIGOCLASE, a rock-forming mineral of the group of felspars (*q.v.*).

OLIPHANT, LAURENCE (1829–1888), British author, son of Anthony Oliphant (1793–1859), was born at Capetown, U. of S. Af. His father was then attorney general in Cape Colony, but was soon transferred as chief justice to Ceylon. The boy's education was of the most desultory kind. In the years 1848 and 1849 he accompanied his parents on a tour on the continent of Europe. In 1851 he accompanied Jung Bahadur from Colombo to Nepal and found material for his first book, *A Journey to Khatmandu* (1852). From Nepal he returned to Ceylon, then to England and then to Russia, after which he wrote *The Russian Shores of the Black Sea in the Autumn of 1852, and a Tour through the Country of the Don Cossacks* (1853). Between 1853 and 1861 he was successively secretary to Lord Elgin during the negotiation of the Canada Reciprocity treaty at Washington, D.C., the companion of the duke of Newcastle on a visit to the Circassian coast during the Crimean War, and Lord Elgin's private secretary on his expedition to China. Each of these experiences produced a pleasant book of travel. In 1861 he was appointed first secretary in Japan and might have made a successful diplomatic career if it had not been interrupted, almost at the outset, by a night attack on the legation, in which he nearly lost his life. It seems probable that he never properly recovered from this affair. He returned to England and resigned the service and was elected to parliament in 1865 for the Stirling burghs.

Oliphant did not show any conspicuous parliamentary ability, but made a great success by his vivacious and witty novel *Piccadilly: a Fragment of Contemporary Biography* (1870). He fell, however, under the influence of the spiritualist prophet Thomas Lake Harris, who about 1861 had organized a small community, the Brotherhood of the New Life, which at this time was settled at Brocton on Lake Erie where Oliphant spent many years living as a farm labourer. As late as Dec. 1878 he continued to believe that Harris was an incarnation of the Deity.

In 1879 he visited Palestine and in 1881 he crossed again to the United States. On this visit he finally broke with Harris. He and his wife (the former Alice Le Strange) settled at Haifa in Palestine.

There they wrote together the strange book called *Sympneumata: Evolutionary Forces Now Active in Man* (1884), and in the next year Oliphant produced there his novel *Masollam,* which may be taken to contain its author's latest views with regard to the personage whom he long considered as "a new Avatar." One of his cleverest works, *Altiora peto,* had been published in 1883.

In 1886 his wife died of fever. He was persuaded that after death he was in much closer relation with her than when she was still alive and conceived that it was under her influence that he wrote his *Scientific Religion.* In Nov. 1887 he went to England to publish that book. By the Whitsuntide of 1888 he had completed it and started for the U.S. Oliphant married, as his second wife, a granddaughter of Robert Owen. They were starting for Haifa when he died, at Twickenham, on Dec. 23, 1888.

See Margaret Oliphant, *Memoir of the Life of Laurence Oliphant and of Alice Oliphant His Wife* (1892). (M. G. D.; X.)

OLIPHANT, MARGARET OLIPHANT (1828–1897), British novelist and historical writer, daughter of Francis Wilson, was born at Wallyford, near Musselburgh, Midlothian, in 1828. Her childhood was spent at Lasswade (near Dalkeith), Glasgow and Liverpool. She had long been a regular contributor to *Blackwood's* and had written some novels when she married in 1852 her cousin Frank Wilson Oliphant. They settled at Harrington square in London. Her husband was an artist, principally in stained glass. She died at Wimbledon on June 25, 1897. Her *Autobiography* gives a touching picture of her domestic life. Mrs. Oliphant was one of the most popular writers of her time. She wrote more than 120 books. Among the best known are the novels *Adam Graeme* (1852), *Miss Marjoribanks* (1866) and the short stories collected in the *Chronicles of Earlingford.*

OLIPHANT or **OLIFANT,** the large signal horn of the middle ages, made, as its name indicates, from the tusk of an elephant. The oliphant was the instrument of knights and men of high degree.

OLIVARES, GASPAR DE GUZMAN, Count of Olivares and Duke of San Lúcar (1587–1645), Spanish royal favourite and minister, born in Rome, Jan. 6, 1587. Combining his inherited title of count with that of duke granted him by Philip IV, he became commonly known as *el conde-duque.* Philip III had appointed him to the household of the heir apparent, over whom he obtained such influence that from the beginning of the new reign all papers requiring the royal signature were sent first to the count-duke.

For 22 years, from 1621, Olivares directed the policy of Spain. It was a period of disaster abroad and of rebellion at home, for which the minister was inevitably held responsible, until he became the accepted model of a grasping and incapable favourite. History has modified the harshness of this judgment. A man of great energy and resolve, ambitious less for wealth than for power, he was also a Maecenas of letters and the arts and was much painted by Velazquez.

Most of the errors of Olivares' foreign policy—the renewal of war with the Netherlands in 1621, intervention in the Thirty Years' War, lesser wars in Sicily—were supported by king, church and the country at large. Where his initiative was most personal, and most disastrous, was in his internal policy of consolidating peninsular unity by force, in defiance of regional interests. The resulting revolts which took place in Catalonia and Portugal in 1640 were the immediate cause of his fall, though only in Jan. 1643, and reluctantly, did Philip part with him, under pressure of a strong court intrigue headed by the queen.

Olivares retired to Toro in the province of Zamora, where he composed, or inspired, an able apology which was confiscated by the Inquisition. He died there on July 22, 1645, driven mad by fear that Philip would accede to the persisting demands, chiefly of the Aragonese, for his head.

OLIVE (*Olea europaea*), the plant that yields the olive oil of commerce, belonging to a section of the family Oleaceae, of which it has been taken as the type. The genus *Olea* includes about 35 species, very widely scattered, chiefly over the old world, from the Mediterranean basin to South Africa and New Zealand. The wild olive is a small tree or bush of rather straggling growth, with thorny branches and opposite oblong pointed leaves, dark grayish-green above and, in the young state, hoary beneath with whitish scales; the small white flowers, with four-cleft calyx and corolla, two stamens and bifid stigma, are borne on the last year's wood, in racemes springing from the axils of the leaves. In the cultivated forms (*O. europaea,* var. *sativa*) the tree acquires a more compact habit, the branches lose their spinous character, while the young shoots become more or less angular; the leaves are always hoary on the underside and are generally lanceolate in shape. The fruit may be globular, oblong or even crescent shaped and when ripe is usually purplish black in colour. The wild olive is found in most countries around the Mediterranean but is probably a native of Syria and the maritime parts of Asia Minor. It was cultivated on the island of Crete as early as 3500 B.C.

The olive tree is of rather slow growth, but after long years of natural development the trunk often attains a considerable diameter. Augustin Pyrame de Candolle records one exceeding 23 ft. in girth, its age being estimated at 700 years. The tree in cultivation seldom exceeds 30 ft. in height and is generally kept much smaller by frequent pruning. The wood, of a yellow or light greenish-brown hue, is often finely veined with a darker tint and, being very hard and close grained, is valued by the cabinet-maker and turner.

Distribution.—At what remote period of human progress the wild olive became the fruitful garden olive it is impossible to conjecture. Some trees yielded with little labour a valuable oil, and this product became a symbol of peace and good will among the warlike barbarians. At a later period the oil was conveyed, as an article of trade, to neighbouring nations, and the plant doubtless soon followed.

In the Homeric world, as depicted in the *Iliad,* olive oil is known only as a luxury of the wealthy, an exotic product prized chiefly for its value in the heroic toilet, but there is no mention of the cultivation of the tree. Whenever it may have been introduced, tradition points to the limestone hills of Attica as the seat of its first cultivation on the Greek peninsula. By the time of Solon the olive had so spread that he found it necessary to enact laws to regulate the cultivation of the tree in Attica, from which country it was probably distributed gradually to all the Athenian allies and tributary states.

In Latin Italy the cultivation seems to have spread slowly, for it was not until the consulship of Pompey that the production of oil became sufficient to permit of its exportation. In Pliny's time it was already grown abundantly in the two Gallic provinces and in Spain; indeed, in the earlier days of Strabo the Ligurians supplied the Alpine barbarians with oil, in exchange for the wild produce of their mountains. Along the southern shore of the Mediterranean the tree was carried by the Phoenicians, at a remote period, to their numerous colonies in Africa and then into Spain.

Yielding a substitute for the butter and animal fats consumed by the races of the north, the olive, among the southern nations of antiquity, became an emblem not only of peace but of national wealth and domestic plenty; the branches borne in the Panathenaea, the wild olive spray of the Olympic victor and the olive crown of the Roman conqueror at ovation alike typified gifts of peace that, in a barbarous age, could be secured by victory alone. Among the Greeks the oil was valued as an important article of diet as well as for its external use. The Roman people employed it largely in food and cookery and the wealthy considered it an indispensable adjunct to the toilet; and in the luxurious days of the later empire it became a favourite axiom that long and pleasant life depended on two fluids, "wine within and oil without." The gourmet of the empire valued the unripe fruit, steeped in brine, no less than his modern representative, and pickled olives have been found among the buried stores of Pompeii.

In modern times the olive has been spread widely over the world. The tree was introduced into Chinese agriculture and became an important addition to the resources of the Australian planter. It was likewise successfully introduced into parts of Cape of Good Hope, Union of South Africa.

The olive is grown mainly for oil, the average annual world output usually averaging in the neighbourhood of 1,000,000 tons. Olive oil weighs approximately 7.6 lb. per gallon. Spain leads with 38% of the total production, followed in order of importance by

Italy, Greece, Portugal, Tunisia and Turkey. Olives and olive products form about 6% of the total agricultural production of Spain, three-fourths of the total area in olives being in the southern provinces, such as Jaén, Córdoba and Sevilla. Only 1.5% of Spanish olives are used for green pickles, the rest being pressed for oil. Of the 20 or more varieties grown in southern Spain, the Sevillano and Manzanillo are preferred for pickling, while the Zorzalena is principally used for oil.

OLIVE (OLEA EUROPAEA)

In Italy the olive is second only to the grape as a horticultural crop. Specialized olive culture, where olive trees occupy the major portion of the land, constitutes 2.6% of the area of Italy; associated olive culture, with olives only a secondary crop, covers another 4.4% of the area. The province of Puglia is credited with 721,000 ac. of specialized olive orchards —more than twice that of Calabria, the next in importance. Sicily leads in the total area devoted to mixed olive culture. More than 85% of Italian olive trees are grown on hills and mountainsides rather than on the plains. Almost the entire production of olives in Italy is used for oil, a very small percentage being used for table olives as dried, salted and pickled fruit. The number of olive varieties grown is from 150 to 300, depending upon the authority consulted, each zone or region having its favourites, such as Corregiolo, Leccino and Morinello in the central provinces.

Specialized olive culture is an important industry on hillsides throughout Greece.

While olives in Greece are grown mostly for oil, this country is also one of the principal exporters of table olives, consisting of black fruit dried, processed in oil or salted, the last being well known in world trade as Greek olives.

In Portugal olive trees are of first importance, the chestnut, fig and carob following in order. Olive culture is mainly concentrated in the central provinces, which possess about two-thirds of the total area planted to this fruit tree. Ninety per cent of Portuguese olive oil is usually consumed in the country.

In Tunisia, olive culture reached its highest development during the Roman occupation of North Africa. It is estimated that the olive orchards covered 2,500,000 ac. when the Arabs conquered the country about A.D. 700. Ancient Rome taxed this province 300,000 gal. of olive oil yearly, and one of the cities near the eastern coast is reputed to have built a conduit solely for the purpose of transporting oil to its seaport. Remains of more than 1,000 oil mills are said to exist in the 100 sq.mi. around Suffetula alone. In the region of Sfax are found optimum conditions for development of olive trees and fruit, so that 30% of all Tunisian olives are grown in that vicinity. More than 90% of the olive production of Tunisia is pressed for oil. The Chemlali is the most common variety and has a high oil content. Tunisia ordinarily supplies many markets with oil for direct consumption, including France, Great Britain and the United States. Algeria is also an important producer of olives for oil.

Olives form the most important tree crop of Anatolia in Turkey, especially on the seaward slopes. The government took steps to promote the industry and to encourage the grafting of fruitful varieties on wild olive trees.

Olives are grown to some extent in the arid regions of South America, and interest in olive culture has been stimulated in various ways. In the United States commercial olive culture is confined almost entirely to California, where the industry is based mostly upon the production of large-sized olives for processing rather than for oil. Thus, California olive oil output is normally less than 1% that of Spain.

Of the average annual production of approximately 50,000 tons, 38% is pressed for oil and 18% is for green pickles, fresh fruit shipments and for other uses. The varieties, all from old world countries, are, in order of importance, Mission, Manzanillo, Sevillano and Ascolano.

The canned ripe olive pack of California averages about 1,500,000 cases of 24 no. 2½ cans, with sizes of fruit in the cans ranging from small to large, mammoth, giant, colossal and even to super-colossal. A ton of ripe olives produces approximately 70 cases of canned fruit.

Ripe olive prices to the grower are based upon the size of fruit and increase rapidly with increase in size. Crops of five tons to the acre are not uncommon, but it is the aim of the grower to get moderate production of large-sized fruit annually rather than alternate heavy and light crops.

Propagation and Culture.—In some Mediterranean countries the desired varieties are grafted on wild olive trees which grow naturally on the hillsides. Seedling stocks are sometimes grown in nurseries, then grafted, but olive trees so propagated may not be any more fruitful than trees of the same variety growing on their own roots. Cuttings are therefore almost universally used for olive tree propagation. These may be of branches several inches in diameter and five to six feet long, planted in the ground where the tree is to remain, or of shorter and smaller pieces planted in nursery rows. The large knots or ovoli which naturally grow at the base of olive trees are sometimes chiselled off and planted, their sprouts being treated as cuttings. In California the trees are grown either from hardwood or softwood cuttings. Cuttings of mature wood placed in sand with bottom heat in February form roots and make a short growth by fall. Softwood olive cuttings are made in October of mature terminal twigs about five inches long, and placed close together in sand for rooting. The following May the rooted cuttings are set in nursery rows where they grow for two years, after which they can be transplanted to the orchard.

In unirrigated orchards of the old world the trees are widely spaced, as much as 75 ft. apart in Tunisia. In California, where irrigation is the rule, the trees are spaced 30–40 ft. apart, depending upon the variety. Trees come into bearing at 5 years of age but are not in full production until 15 or 20 years old. In Spain and Italy olive trees are pruned rather heavily each year or every other year in order to promote new growth. Experiments in California, however, show that Mission olive trees unpruned during the first four or five years develop much more rapidly and have a larger trunk than trees pruned each year. Furthermore, pruning of bearing trees has neither increased the yield nor substantially improved the size of fruit. The advantage of pruning appears to be the greater convenience in harvesting and the more effective control of pests and diseases. Olives intended for oil are sometimes beaten from the trees with poles, but this method of harvesting is injurious to both tree and fruit. Olives for canning are carefully harvested by hand and transported in boxes to the processing plants. Both animal manures and commercial fertilizers are commonly used in European olive orchards. Fertilizer experiments in California show that nitrogen is the only element which has appreciably increased the yield of olives.

The extraction of oil from olives is largely a mechanical process. As soon after harvesting as possible the fruit is first crushed beneath stone or steel rollers, then placed in press cloths which are stacked one above the other somewhat like broad flat cheeses. Hydraulic presses are commonly used, the first oil secured being known as virgin oil. Olives vary considerably in oil content, which ranges from 50% to 60% of the dry weight of pit-free pulp. Ripe olives contain a bitter principle which, in order to make the fruit palatable, is commonly neutralized by submersion in a lye solution. The natural black colour of the fruit is retained by aeration during the pickling process. Pickled olives are packed in cans in a salt solution and sterilized with steam under pres-

sure for one hour at 116° C. Green olives are pickled in barrels, going through a process of lactic acid fermentation.

OLIVEIRA MARTINS, JOAQUIM PEDRO DE (1845–1894), Portuguese writer, was born in Lisbon, and in 1870 was appointed manager of the mine of St. Eufemia near Cordova. In Spain he wrote *O Socialismo,* and developed that sympathy for the industrial classes of which he gave proof throughout his life. Returning to Portugal in 1874, he became administrator of the railway from Oporto to Povoa, residing in Oporto. He entered parliament in 1886, became minister of finance on Jan. 17, 1892, and later vice-president of the Junta do Credito Publico. He died on Aug. 24, 1894. A psychologist, a profound sociologist, a stern moralist and an ardent patriot, Oliveira Martins deserved his European reputation. His *Bibliotheca das sciencias sociaes,* a veritable encyclopaedia, comprises literary criticism, socialism, economics, anthropology, histories of Iberian civilization, of the Roman republic, Portugal and Brazil. Toward the end of his life he specialized in the 15th century and produced two volumes, *Os fithos de D. João I* (1891) and *A vida de Nun' Alvares* (1893), leaving unfinished *O principe perfeito* (1896), a study on King John II, edited by Henrique de Barros Gomes. The chief characteristics of the man—psychological imagination combined with realism and a gentle irony—make his strength as a historian and his charm as a writer. He drew admirable portraits; in his *Historia de Portugal* and *Portugal Contemporaneo* (1881) those of King Pedro I and Herculano are among the best known.

See Moniz Barreto, *Oliveira Martins, estudo de psychologia* (Paris, 1887), a remarkable study; F. Diniz D'Ayalla, *Os Ideaes de Oliveira Martins* (1897), which contains an admirable statement of his ideas, philosophical and otherwise; Anthero de Quental, *Oliveira Martins* (1894); *Diccionario bibliographico portuguez,* xii, 125; P. Leal, *Sociologia de Oliveira Martins* (Pôrto, 1945).

OLIVENITE, a mineral consisting of basic copper arsenate with the formula $Cu_2(OH)AsO_4$. It crystallizes in the orthorhombic system, and is sometimes found in small brilliant crystals of simple prismatic habit terminated by domal faces. More usually it occurs as globular aggregates of acicular crystals, these fibrous forms often having a velvety lustre. A characteristic feature, and one to which the name alludes, is the olive-green colour, which varies in shade from blackish-green in the crystals to almost white in the variety known as wood copper.

OLIVE OIL is the oil expressed from the fleshy part of the ripened fruit (pericarp) of the olive tree, which is chiefly cultivated in the countries of the Mediterranean basin, also in California, South America and Australia. The ripe fruit contains from 20% to 50% oil, depending on climatic conditions and care in cultivation. Some varieties contain more oil than others.

The fruit intended for oil production is gathered when fully ripe. Virgin oil, so termed because it is carefully prepared from selected sound fruits in the first pressing, is seldom exported in its natural state but forms the basis of edible export types of the finest qualities. The apparatus used in expressing the oil (crushing) varies from the most primitive Roman presses, consisting of conical stones, hand or mule propelled, to the most modern types of hydraulic presses. To obtain the best quality edible oil it is essential that the oil be removed from contact with the residual and putrescible pulp as soon as possible; otherwise the consequent formation of free fatty acids may induce rancidity. In practice the residual pulp is subjected to a second pressing with hot water yielding an oil of higher free fatty acid content, called *lampante* after its primitive use as a fluid for lamps. This oil of second pressing is then subjected to a refining process of decolorization, deacidification and deodorization and is commercially known as refined olive oil. It is largely used to blend with virgin oils for edible export types.

A third type of oil, lowest in quality, is obtained from the residue by a process of extraction with a volatile solvent, usually carbon disulphide. This oil is commercially known as sulphur olive oil or olive oil foots, and is largely used in the production of soap, especially green and mottled laundry soaps.

Edible olive oil should be practically devoid of free fatty acids. The U.S. Pharmacopoeia requires olive oil not to exceed 1.41%; however, most export types do not exceed 1%. It varies in colour from water white (refined) to golden yellow. Certain types, pressed from unripe fruit, will have a greenish tint. Almost every producing country produces oils of varying characteristics and qualities, depending on the districts in which the olive is grown and the degree of the ripeness of the fruit.

Oil Production of Principal Olive-Growing Countries
(In short tons)

Countries	1951	1935–39 Average
France	13,000	8,000
Greece	15,200	131,500
Italy	389,700	265,000
Portugal	117,000	64,000
Spain	770,000	357,100*
Yugoslavia	3,200	5,900*
Israel (Palestine)	200	[illegible]
Syria }	5,500	12,500
Lebanon }	6,500	
Turkey	28,000	20,000
French Morocco	27,000	13,000*
Tunisia	50,000	49,300
Libya	4,000	2,600
All countries	1,609,300	971,200
World production	1,620,000	975,000

*Average figures based on less than five years.

Each oil has definite characteristics which generally consist of glycerides made up of saturated or unsaturated fatty acids. The majority of the glycerides are not made up of one fatty acid, but of combinations. The average composition of olive oil is approximately as follows: oleic acid, 70%–85%; linoleic acid, 4%–12%; palmitic acid, 7%–14%; and stearic acid 1%–2%.

Olive oil is sometimes adulterated with other vegetable and seed oils. However, any adulteration that may be used can be detected by chemical tests that are specific for each adulterant.

Pure olive oil is largely used for comestible purposes (cooking, salads, etc.) and in the preservation of foods (sardine canning, etc.); it is also used in the textile industry (wool combing), in the manufacture of high-class toilet preparations and cosmetics, in the pharmaceutical industry for medicinal purposes and in the manufacture of high-class Castile soap. (J. M. CN.)

OLIVER, ISAAC PETER (d. 1617), miniature painter, was born at Rouen of Huguenot parents who brought him to London *c.* 1568. He died, aged between 50 and 60, in London, and was buried at St. Anne's, Blackfriars. He studied under N. Hilliard, and was in Venice in 1596. Apparently he married Sarah, daughter of Marc Gheeraerts, the portrait painter, in 1602. Besides miniature portraits he painted small religious and classical pictures. His patrons included Queen Elizabeth I, Henry, prince of Wales, Sir Philip Sidney and Anne of Denmark. His earlier miniatures carry on the fine tradition of Hilliard; his later are influenced by the oil painters of that time. Oliver's work is in the first rank of British miniatures.

His son PETER OLIVER (*c.* 1594–1647) was his pupil and capably carried on his later style. Peter copied Italian pictures in miniature, and his signed and dated portraits range from 1619 to 1646. He is said to have painted landscapes in miniature.

OLIVES, MOUNT OF, the ridge, 2,680 ft. above sea level, facing the Temple mount at Jerusalem on the east and separated from it by the Vale of Kidron: Arabic, *Jebel et-Tōr.* Of the four distinct elevations on the ridge the southernmost is the scene of Solomon's idolatrous worship. The mount is referred to only four times in the Old Testament. Jesus crossed it on his entry into Jerusalem. The Ascension took place "over against Bethany" (Luke xxiv, 50), probably in one of the secluded ravines of the eastern slope. The tradition that the Ascension was from the central eminence of the hill dates from Eusebius Caesarea, and over a sacred cave in that place there was built a succession of sanctuaries. The latest chapel on the site was built by the crusaders and modified by the Moslems, who erected beside the entrance to the *haram* a minaret.

Close by is the grotto of St. Pelagia (d. 457) and a short way down the hill the rock-cut cave called the "Tomb of the Prophets." A tradition of the middle ages identified Olivet with

the Mount of Transfiguration. At its foot was the Garden of Gethsemane (*q.v.*).

At the present day there stands on Mt. Scopus, a continuation of the Mt. of Olives, the new Hebrew university opened by Lord Balfour in 1925. The German hospice was opened in 1910. The earthquake of July 11, 1927, was particularly severe in the area of the mount. (E. Ro.)

OLIVETANS, one of the lesser monastic orders following the Benedictine rule, founded by St. Bernard Tolomei, a Sienese nobleman. At the age of 40, when the leading man in Siena, he retired along with two companions to live a hermit's life at Accona, a desert place 15 mi. to the south of Siena, 1313. Soon others joined them, and in 1324 John XXII approved of the formation of an order, the Benedictine rule being taken as the basis of the life. Partly from the olive trees that abound there, and partly out of devotion to the Passion, Accona was christened Monte Oliveto, whence the order received its name. By the end of the 14th century, there were more than 100 monasteries, chiefly in Italy; and in the 18th there still were 80, one of the most famous being San Miniato at Florence. The Olivetans have a house in Rome and in a few other cities.

OLIVIER OF RAMSDEN, SYDNEY OLIVIER, 1ST BARON, cr. 1924 (1859–1943), English statesman and writer, was educated at Tonbridge and Corpus Christi college, Oxford. He entered the colonial office in 1882 and was governor of Jamaica from 1907 to 1913. After his return from Jamaica he was permanent secretary of the board of agriculture (1913–17) and assistant comptroller of the exchequer (1917–20). In 1924 Olivier received a barony, and took office in the Labour government as secretary for India.

Olivier wrote books on colonial questions. He was created K.C.M.G., 1907. He died Feb. 15, 1943.

OLIVINE, a rock-forming mineral composed of magnesium and ferrous orthosilicate, the formula being $(Mg,Fe)_2SiO_4$. The name alludes to its olive-green colour and is often applied incorrectly by jewellers to various green stones. The transparent varieties, or "precious olivine," used in jewellery, are known as chrysolite (*q.v.*) and peridot.

Olivine crystallizes in the orthorhombic system, but distinctly developed crystals are comparatively rare, the mineral more often occurring as compact or granular masses or as grains and blebs embedded in the igneous rocks of which it forms a constituent part. The hardness is $6\frac{3}{4}$; the specific gravity 3.27–3.37, but reaching 3.57 in the highly ferruginous variety known as hyalosiderite. The amount of ferrous oxide varies from 5% (about 9% in the gem varieties) to 30% in hyalosiderite. The depth of the green, or yellowish-brown, colour also varies with the amount of iron. The lustre is vitreous. The indices of refraction (1.66 and 1.70) and the double refraction are higher than in many other rock-forming minerals; and these characteristics, together with the indistinct cleavage, enable it to be readily distinguished in thin rock sections under the microscope. The mineral is decomposed by hot hydrochloric acid with separation of gelatinous silica; it often contains small amounts of nickel and titanium dioxide; the latter replaces silica, and in the variety known as titan olivine reaches 5%.

Olivine is a common constituent of many basic and ultrabasic rocks, such as basalt, dolerite, gabbro and peridotite; and the dunite, of Dun mountain near Nelson in New Zealand, is an almost pure olivine rock. It also occurs as an accessory constituent of some granular dolomitic limestones and crystalline schists. With enstatite it forms the bulk of the material of meteoric stones; and in another type of meteorites large blebs of glassy olivine fill spaces in a cellular mass of metallic iron.

Olivine is especially liable to alteration into serpentine (hydrated magnesium silicate); the alteration proceeds from the outside of the crystals and grains or along irregular cracks in their interior, and gives rise to the separation of iron oxides and an irregular network of fibrous serpentine, which in rock sections presents a very characteristic appearance. Large greenish-yellow crystals from Snarum in Buskerud, Nor., at one time thought to be crystals of serpentine, really consist of serpentine pseudomorphous after olivine. Many of the large rock masses of serpentine have been derived by the serpentinization of olivine rocks. Olivine also sometimes alters, especially in crystalline schists, to a fibrous, colourless amphibole, to which the name pilite has been given. By weathering processes it alters to limonite and silica.

Closely related to olivine are several other species, which are included together in the olivine group: they have the orthosilicate formula R''_2SiO_4, where R'' represents calcium, magnesium, iron, manganese and rarely zinc; they all crystallize in the orthorhombic system, and are isomorphous with olivine. These include: monticellite, $CaMgSiO_4$, a rare mineral occurring as yellowish-gray crystals and grains in granular limestone at Monte Somma, Vesuvius; forsterite, Mg_2SiO_4, as colourless or yellowish grains embedded in many crystalline limestones; fayalite, Fe_2SiO_4, or iron olivine, a dark brown or black variety occurring as nodules in volcanic rock; tephroite, Mn_2SiO_4, a gray (τεφρός, ash-coloured), mineral occurring in Sweden and New Jersey. (L. J. S.)

OLLIVIER, OLIVIER ÉMILE (1825–1913), French statesman, was born at Marseilles on July 2, 1825. On the establishment of the second republic his father, DEMOSTHENES OLLIVIER (1799–1844), secured for him the position of commissary-general of the department of Bouches-du-Rhône. His repression of a Socialist outbreak at Marseilles commended him to Gen. Louis Cavaignac, who made him prefect of the department. His removal to the prefecture of Chaumont (Haute-Marne) he ascribed to his father's enemies. He therefore resigned from the civil service to take up practice at the bar.

He re-entered political life in 1857 as deputy for the 3rd circumscription of the Seine. His candidature had been supported by the *Siècle,* and he joined the constitutional opposition. With Alfred Darimon, Jules Favre, J. L. Hénon and Ernest Picard he formed the group known as Les Cinq, which wrung from Napoleon III some concessions in the direction of constitutional government. The imperial decree of Nov. 24, permitting the insertion of parliamentary reports in the *Moniteur,* and an address from the Corps Législatif in reply to the speech from the throne, were welcomed by him as a first instalment of reform. This acquiescence marked a considerable change of attitude, for only a year previously a violent attack on the imperial government, in the course of a defense of Étienne Vacherot, brought to trial for the publication of *La Démocratie,* had resulted in his suspension from the bar for three months. He gradually separated from his old associates, who grouped themselves around Jules Favre, and during the session of 1866–67 Ollivier helped to form a third party, which definitely supported the principle of a liberal empire. This led to a struggle of personal rivalry between Ollivier and Eugène Rouher, the minister of state, who attempted, by the issue of his *Senatus-consulte* (July 1866), to uphold the constitution of 1852. On Jan. 19, 1867, an imperial decree was issued, restoring the right of interpellation to the deputies. A promise was also inserted in the *Moniteur* of a relaxation of the stringency of the press laws and of concessions in respect of the right of public meeting. On June 28, 1869, the third party, which consisted of 116 members, with the support of the left, obtained a majority in the chamber for their demand for a responsible ministry "and the right of the Legislative Body to regulate the essential conditions of its own activity." The emperor prorogued the legislative body on July 13, and on the same day appointed Rouher president of the senate. The *sénatus-consulte* of Sept. 8, 1869, gave the two chambers the ordinary parliamentary rights. On Nov. 29 the chambers again met and on Dec. 28 the emperor was obliged to give in to the third party's demands. He dismissed Rouher and entrusted Ollivier with the formation of a responsible ministry of which Ollivier was really premier, although that office was not nominally recognized by the constitution. The new cabinet, known as the ministry of the Jan. 2, had a hard task before it, complicated a week after its formation by the hostile manifestation following the shooting of Victor Noir by Prince Pierre Bonaparte. Ollivier immediately summoned the high court of justice for the judgment of Prince Bonaparte and Prince Joachim Murat. His ministry included four members of the right centre and four of the left centre. In March his position obliged him to propose a revision of the constitution, and on April 20, a *sénatus-consulte*

was issued which accomplished the transformation of the Empire into a constitutional monarchy. Ollivier, however, still had to face violent opposition from the Republicans and Socialists. He had arrested Rochefort on Feb. 9 for his presence at the funeral of Victor Noir, and he arrested also the editors of the *Marseilléien.* Neither concessions nor firmness sufficed to appease the "Irreconcilables" of the opposition, who since the relaxation of the press laws were able to influence the electorate. On May 8, however, the amended constitution was submitted to a plebiscite, which resulted in a vote of nearly seven to one in favour of the government. The most distinguished members of the Left in his cabinet—L. J. Buffet, Napoléon Daru and Talhouët Roy—resigned in April on the question of the plebiscite. Ollivier himself held the ministry of foreign affairs for a few weeks, until Daru was replaced by the duc de Gramont.

The revival of the candidature of Prince Leopold of Hohenzollern-Sigmaringen for the throne of Spain early in 1870 disconcerted Ollivier's plans. The French government, following Gramont's advice, instructed Benedetti to demand from the king of Prussia a formal disavowal of the Hohenzollern candidature. Ollivier allowed himself to be gained by the war party. The story of Benedetti's reception at Ems and of Bismarck's manipulation of the Ems telegram is told elsewhere. (*See* BISMARCK.) It is unlikely that Ollivier could have prevented the eventual outbreak of war, but he might perhaps have postponed it at that time, if he had taken time to hear Benedetti's account of the incident. He was outmanoeuvred by Bismarck, and on July 15 he made a hasty declaration in the Chamber that the Prussian government had issued to the powers a note announcing the rebuff received by Benedetti. He obtained a war vote of 500,000,000 francs, and used the fatal words that he accepted the responsibility of the war "with a light heart," saying that the war had been forced on France. On Aug. 9, with the news of the first disaster, the Ollivier cabinet was driven from office, and its chief sought refuge in Italy. He returned to France in 1873, and occupied himself with writing the apology for his government, *L'Empire libéral* (1895 *seq.*). His first wife, Blandine Liszt, was the daughter of the Abbé Liszt by Mme. d'Agoult (Daniel Stern). She died in 1862, and Ollivier married in 1869 Mlle. Gravier. He died at St. Gervais-les-Bains on Aug. 30, 1913.

His other works include *Démocratie et liberté* (1867), *Le Ministère du 2 janvier, mes discours* (1875), *Principes et conduite* (1875), *L'Église et l'État au concile du Vatican* (2 vols., 1879), *Solutions politiques et sociales* (1893), *Nouveau Manuel du droit ecclésiastique français* (1885).

See M. T. Ollivier, *Emile Ollivier; sa jeunesse d'apres son journal et sa correspondance* (1918).

OLMEDO, JOSÉ JOAQUÍN DE (1780–1847), Ecuadorian poet and politician, was born in Guayaquil on March 20, 1780. Sent to Europe in 1825 as Peruvian diplomatic representative, he returned in 1828 and in 1830 was elected vice president of the recently created (1830) independent republic of Ecuador, but declined the honour. In 1845 he headed a successful revolt and, having been chosen first member of the provisional government, was a candidate for the presidency, but was not elected. He died in Guayaquil on Feb. 19, 1847. A neo-classicist, Olmedo has been called by a distinguished Spanish critic "one of the three or four great Spanish-American poets, if not the first." He is best known for his ode *La Victoria de Junín, Canto a Bolívar* (1825), commemorating the final overthrow of Spain in America, and the ode *Al General Flores, Vencedor en Miñarica* (1835), written after the defeat of a revolt against the government.

OLMSTED, FREDERICK LAW (1822–1903), American landscape architect, was born in Hartford (Conn.), on April 27, 1822. He already had an adventurous career when he published his *Journeys and Explorations in the Cotton Kingdom* (1861), which gave a picture of the conditions surrounding American slavery that had great influence on British opinion, and was much quoted in the controversies at the time of the Civil War. During the war he was the untiring secretary of the U.S. sanitary commission.

When Central Park, New York city, was projected, he, in conjunction with Vaux, proposed the plan which, in competition with more than 30 others, won first prize. Olmsted was made superintendent to carry out the plan. This was practically the first attempt in the United States to apply art to the improvement or embellishment of nature in a public park; it attracted great attention, and the work was so satisfactorily done that he was engaged thereafter in most of the important works of a similar nature in America—Prospect park, Brooklyn; Fairmount park, Philadelphia; South park, Chicago; Riverside and Morningside parks, New York; Mount Royal park, Montreal; the grounds surrounding the Capitol at Washington, and at Leland Stanford University at Palo Alto (Calif.), and many others. He developed the bare stretch of lake front at Chicago into the World's Fair grounds, contributing much to the architectural beauty and the success of the exposition. He was greatly interested in the Niagara reservation, made the plans for the park there, and also did much to influence the State of New York to provide the Niagara park.

He was the first commissioner of the national park of the Yosemite and the Mariposa grove, directing the survey and taking charge of the property for the State of California. He also held directing appointments under the cities of New York, Boston, Philadelphia, Baltimore, Wilmington and San Francisco, the joint committee on buildings and grounds of Congress, the Niagara Falls Reservation commission, the trustees of Harvard, Yale, Amherst and other colleges and public institutions. After 1886 he was largely occupied in laying out an extensive system of parks and parkways for the city of Boston and the town of Brookline, and on a scheme of landscape improvement of Boston harbour. He died on August 28, 1903.

OLMÜTZ: *see* OLOMOUC.

OLNEY, RICHARD (1835–1917), American statesman, was born at Oxford, Mass., on Sept. 15, 1835. He graduated at Brown university in 1856, and at the law school of Harvard university in 1858. In 1859 he began the practice of law at Boston, Mass., and attained a high position at the bar. He served in the State House of Representatives in 1874, and in March 1893 became attorney-general of the United States in the cabinet of President Cleveland. In this position, during the strike of the railway employees in Chicago in 1894, he instructed the district attorneys to secure from the Federal courts writs of injunction restraining the strikers from acts of violence, and thus set a precedent for "government by injunction." He also advised the use of Federal troops to quell the disturbances in the city, on the ground that the Government must prevent interference with its mails and with the general railway transportation between the States. Upon the death of Secretary W. Q. Gresham (1832–95), Olney succeeded him as secretary of State on June 10, 1895. He became specially prominent in the controversy with Great Britain concerning the boundary dispute between the British and Venezuelan Governments (*see* VENEZUELA), and in his correspondence with Lord Salisbury gave an extended interpretation to the Monroe Doctrine which went considerably beyond previous statements on the subject. In 1897, at the expiration of President Cleveland's term, he returned to the practice of the law. He died in Boston, Mass., on April 8, 1917.

OLNEY, a market town of Buckinghamshire, England, on the Ouse, 59 mi. N.N.W. of London on the London Midland Region railway. Pop. (1931) 2,438. The church of St. Peter and St. Paul is Decorated. William Cowper lived there from 1767 until 1786. John Newton, curate of Olney, had the assistance of Cowper in the production of the Olney hymns. The trade of Olney is principally agricultural, but boots and shoes are manufactured.

OLNEY, a city of Young county, Tex., U.S., 90 mi. N.W. of Fort Worth, on the Wichita Falls and Southern railroad.

By the federal census the population of Olney was 3,753 in

1950; 3,497 in 1940; 4,138 in 1930. It is in a rich agricultural, stock-raising and oil-producing section. More than 2,000 producing wells are within a ten-mile radius.

OLOMOUC, a town in Morava Slezsko, Czechoslovakia, at the confluence of the Bystrice and the Morava. Pop. (1930) 66,442, of which 15,017 were Germans. Near the head of a fertile gulf, floored with sandy loam and loess, and having a sheltered climate, it is a market for cereals and cattle and such prepared materials as malt, meal, beer, spirits, starch and sugar.

Until 1640 Olomouc was the recognized capital of Moravia. Originally fortified by Maria Theresa it was, until 1886, one of the strongest fortresses in central Europe and withstood a seven-weeks' attack of Frederick the Great in 1758, but the site of the fortification is now occupied by park, gardens and promenade. Notable buildings are the 14th-century cathedral in Gothic style, with a 328-ft. tower, the 15th-century Mauritius church, also Gothic, and the 15th-century town hall and museum. Olomouc was made the see of a bishop in 1073 and in 1777 was raised to the rank of an archbishopric. It was occupied by Germany in 1939.

OLONA (*Touchardia latifolia*), a shrub of the nettle family (Urticaceae), native to the Hawaiian Islands, where it has long been cultivated as a fibre plant. The bast fibre obtained from the young shoots possesses remarkable tensile strength, being three times as strong as that of the finest grades of abacá fibre (*q.v.*). Because of its great pliability olona fibre is readily woven into cloth or made into cordage. Another valuable quality is its unusual durability in water, making it especially suitable for fish nets.

OLONETS, a former government of northwestern Russia (*see* KARELIA).

OLORON-SAINTE-MARIE, a town of southwestern France, capital of an arrondissement in the department of Basses-Pyrénées, 21 mi. S.W. of Pau on a branch of the Southern railway. Pop. (1946) 10,567. It lies at the confluence of the mountain torrents (locally known as *gaves*) Aspe and Ossau, which, after dividing it into three parts, unite to form the Oloron, a tributary of the Pau. A Celtiberian and then a Gallo-Roman town, known as *Iluro,* occupied the hill on which the old feudal town of Sainte-Croix now stands, still surrounded by remnants of its 14th-century ramparts, between the two rivers; Sainte-Marie lies on the left bank of the Aspe, and the new town on the right bank of the Ossau. Oloron is the seat of a subprefect. The town carries on a thriving trade with Spain by way of the passes of Somport and Anso, chiefly in wool and skins, salt pork and hams, cattle and horses.

OLTEN (1,312 ft.), a town in the canton of Solothurn, Switzerland, at the south foot of the Jura. An important railway centre at the junction of the railways Basle-Luzern (Lucerne), Berne-Zürich and Solothurn-Zürich. Pop. (1941) 15,282.

OLUSTEE, a village of Baker county, Fla., U.S., in the precinct of Olustee, about 46 mi. W. by S. of Jacksonville. Population of the precinct (1950) 350. The village is served by the Seaboard railway. The battle of Olustee, or Ocean Pond (the name of a small body of water in the vicinity), one of the most sanguinary engagements of the Civil War in proportion to the numbers engaged, was fought on Feb. 20, 1864, about 2 mi. east of Olustee, between about 5,500 Federal troops, under Gen. Truman Seymour (1824–91), and about 5,400 Confederates, under Gen. Joseph Finegan, the Federal forces being decisively defeated, with a loss, in killed and wounded, of about one-third of their number, including several officers. The Confederate losses, in killed and wounded, were about 940.

OLYBRIUS, Roman emperor of the west from July 11, to Oct. 23, 472, was a member of a noble family and a native of Rome. After the sack of the city by Gaiseric in 455, he fled to Constantinople, where, about 464, he married Placidia, daughter of Valentinian III. This afforded Gaiseric the opportunity of claiming the empire of the west for Olybrius. In 472 Olybrius was sent to Italy by the emperor Leo to assist the emperor Anthemius against his son-in-law Ricimer, but, having entered into negotiations with the latter, was himself proclaimed emperor and on the murder of his rival ascended the throne unopposed.

See Gibbon, *Decline and Fall,* ch. xxxvi; J. B. Bury, *Later Roman Empire.*

OLYMPIA, the scene of the Olympic games, is in western Peloponnesos on the north bank of the Alpheus (mod. Ruphia), about 11 mi. E. of modern Pýrgos, where the ancient Cladeus tributary flows in from the north. Olympia is bounded on the west by the Cladeus, on the south by the Alpheus, on the east by the ancient racecourses and on the north by low heights. There a conical hill, about 400 ft. high, cut off by a cleft, descends abruptly on Olympia. This is the *Cronion* hill sacred to Cronus.

HISTORY

The importance of Olympia in the history of Greece is religious and political. Religious associations date from the prehistoric age, when a centre of worship is attested by house-remains and early votive offerings found beneath the Heraeum. The earliest extant building is the temple of Hera, which may date in its original form from about 1000 B.C. and retained till Pausanias' time one original column of wood. There were various traditions as to the origin of the games. According to one the first race was between Pelops and Oenomaus, who used to challenge the suitors of his daughter Hippodameia and then slay them. Another attributed the festival to Heracles, either the well-known hero or the Idaean Dactyl of that name. In early times the control of the festival belonged to Pisa, but Elis seems to have claimed some share in it. Sixteen women, representing eight towns of Elis and eight of Pisatis, wove the festal robe for the Olympian Hera. Olympia thus became the centre of an amphictyony (*q.v.*), or federal league under religious sanction, for the west coast of Peloponnesos. It suited the interests of Sparta to join this amphictyony; and, before the list of Olympic victors begins in 776 B.C., Sparta had formed an alliance with Elis. Aristotle saw in the temple of Hera a bronze disk, recording the traditional laws of the festival, on which the name of Lycurgus of Sparta stood next to that of Iphitus, king of Elis. Whatever may have been the age of this disk, the relation which it indicates is well attested. Elis and Sparta, making common cause, had no difficulty in excluding the Pisatans from their proper share in the management of the Olympian sanctuary. Pisa had, indeed, a brief success, when Pheidon of Argos celebrated the 28th Olympiad under its presidency. But this festival, from which Eleans and Spartans were excluded, was afterward struck out of the official register. The destruction of Pisa (before 572 B.C.) by Sparta and Elis put an end to the rivalry: Pisatis, and also Triphylia to the south of it, becoming dependent on Elis. On the religious side of the festival the Eleans had unquestioned supremacy. All candidates were tested at Elis, in the gymnasium, before they were admitted to the athletic competitions at Olympia, and training (usually of ten months) at Elis was regarded as the most valuable preparation. Elean officials, who not only adjudged the prizes, but decided who should be admitted to compete, assumed the title of *Hellanodicae.*

Long before the overthrow of Pisa the list of contests had been so enlarged as to give the celebration a Panhellenic character. Exercises of Spartan type—testing endurance and strength with a special view to war—had almost exclusively formed the earlier program. But as early as the 25th Olympiad the four-horse chariot race was added, an invitation to wealthy competitors from every part of the Hellenic world, and the recognition of a popular spectacular element, as distinct from athletic or military. Horse races were added later. For such contests the hippodrome was set apart. Meanwhile the list of contests on the old racecourse, the stadium, had been enlarged. Besides the original foot race in which the course was traversed once only, there were the double course (*diaulos*) and the "long" foot race (*dolichos*). Wrestling and boxing were combined in the *pancration;* leaping, quoit throwing, javelin throwing, running and wrestling in the *pentathlon.* Under the protection of the Spartans, the festival acquired new importance for, having failed in their plans of actual conquest in the Peloponnesos, they sought at least acknowledged predominance. While therefore the Eleans were the religious supervisors of Olympia the Spartans constituted

themselves its political protectors, enforcing the sanction which the Olympian Zeus gave to the amphictyones, whose federal bond was symbolized by common worship, and punishing violation of that "sacred truce" which was indispensable if Hellenes from all cities were to have peaceable access to the Olympian festival.

Olympia thus became a recognized Panhellenic institution after the establishment of Elean supremacy in 572 B.C.; and to the last remained a central expression of the Greek ideas that the body of man has a glory as well as his intellect and spirit, that body and mind should alike be disciplined, and that it is by the harmonious discipline of both that men best honour Zeus. The significance of Olympia was larger and higher than the political fortunes of the Greeks who met there, and it survived the overthrow of Greek independence. In the Macedonian and Roman ages the temples and contests of Olympia still interpreted the ideal at which free Greece had aimed. Philip of Macedon and Nero are among those who have record in the Altis. According to Cedrenus, a Greek writer of the 11th century (*Synopsis*, i. 326), the Olympian festival ceased to be held after A.D. 393, the first year of the 293rd Olympiad. The list of Olympian victors, which begins in 776 B.C. with Coroebus of Elis, closes with the name of an Armenian, Varastad, who is said to have belonged to the race of the Arsacidae. In the 5th century desolation had set in. The chryselephantine statue of the Olympian Zeus, by Pheidias, was carried to Constantinople, and perished in a great fire, A.D. 476. The Temple of Zeus was dismantled; either by Goths or by Christian zeal, in the reign of Theodosius II. (A.D. 402–450). The temple of Zeus, probably thrown down by earthquakes in the 6th century A.D., and the region south of it became a fortress, constructed from materials found among the ancient buildings.

Excavations.—The German excavations were begun in 1875, and completed in 1881. The deposit of earth over the Altis from the overflowing of the Cladeus had an average depth of 16 ft.; it was also necessary to excavate, especially on the west, the south and the east, several ancient buildings not included within the sacred precinct. Moreover in many places early Greek work had later Greek on top of it, or late Greek work had been overlaid with Roman.

The form of the Altis is not regularly rectangular. The west side is about 215 yd.; the south side is about equally long; the east side, about 200 yd.; the north side, behind the treasure-houses, about 275 yd.

REMAINS WITHIN THE ALTIS

Within the Altis are three main groups of buildings:—(A) chief centres of religious worship; (B) votive buildings; (C) buildings connected with the administration or with the reception of visitors.

A. **Chief Centres of Religious Worship.**—1. There are traces of an altar near the Heraeum older than the great altar of Zeus, and probably the original centre of worship. The great altar of Zeus was of elliptic form; imposed on this basis, in two tiers, and also, lozenge-shaped, was the famous "ash-altar" at which the Iamidae, the hereditary family of seers, practised rites of divination by fire in virtue of which Olympia is saluted by Pindar as "mistress of truth."

2. The *Pelopium,* to the west of the Altar of Zeus, was a small walled precinct in which sacrifices were offered to the hero Pelops. In the middle was a low tumulus of elliptic form. A Doric gateway with three doors gave access on the south-west side.

The three temples of the Altis were those of Zeus, Hera and the Mother of the gods. All were Doric and completely surrounded by a colonnade.

3. *The Temple of Zeus,* south of the Pelopium, stood on a high substructure with three steps. It was probably built about 470 B.C. The colonnades at the east and west ends were of six columns, the north and south sides of thirteen. The cella had a prodomos on the east and an opisthodomos on the west. It was itself divided longitudinally by a double row of columns. The central, and widest, partition was in three sections; the western containing the throne and image of the Olympian Zeus; the middle section, a table and stelae, where, probably, the wreaths were presented to the victors; the eastern was open to the public. On the east pediment was represented in twenty-one colossal figures the moment before the contest between Oenomaus and Pelops; on the western the fight of the Lapithae and Centaurs. The statement of Pausanias that the two pediments were made by Paeonius and Alcamenes is now generally supposed to be an error. On the metopes of the prodomos and opisthodomos were depicted the Twelve Labours of Heracles.

Near this temple was found the statue of a flying goddess of victory—the Nike of Paeonius. (*See* GREEK ART.)

4. *The Temple of Hera* (Heraeum), north of the Pelopium, was on two steps. It is the oldest of extant Greek temples, and may date from about 1000 B.C. It was smaller than the temple of Zeus, and of unusual length relatively to its breadth. It has colonnades of six columns at east and west, and of sixteen at north and south. When Pausanias saw it, one of the two columns of the opisthodomos was of wood; and for long, probably, all the columns of this temple had been wooden, gradually replaced as they decayed in progressively later styles. Only the lower part of the cella wall was of stone, the rest of unbaked brick; the entablature was of wood covered with terra-cotta. The cella—divided, like that of Zeus, by a double row of columns—had four small screens, projecting at right angles from its north and south walls. In the third niche thus formed, from the east, on the north side, was found the Hermes of Praxiteles still preserved in the local museum. (*See* GREEK ARCHAEOLOGY.)

5. *The Temple of the Great Mother of the Gods* (Metroum) was smaller than the Heraeum. It stood to the east of it and had a different orientation. It was on three steps, and had six columns east and west by eleven north and south. The cella had prodomos and opisthodomos. It was probably built in the 4th century, and underwent a Roman restoration.

B. **Votive Edifices.**—These were erected, either by states or by individuals.

1. Twelve *Treasure-houses* on the north side of the Altis, immediately under the Cronion, have the same general character of a Doric temple *in antis,* facing south. Of several the fragments are sufficient for reconstruction. The 2nd and 3rd from the west had been dismantled early for a roadway winding upward towards the Cronion, which is itself older than A.D. 157. This explains the fact that, though we can trace twelve, Pausanias names only ten. Each treasure-house was erected by a Greek state, either as a thank-offering for Olympian victories gained by its citizens, or as a general mark of homage to Olympian Zeus, and to contain the dedicated gifts in which the wealth of the sanctuary consisted. Temple inventories discovered at Delos and at Lindus in Rhodes illustrate how such possessions accumulated at a shrine of Panhellenic celebrity. The treasure-houses were founded by the following states, in order from the west: 1. Sicyon; 2, 3, unknown; 4, Syracuse (referred by Pausanias to Carthage); 5, Epidamnus; 6, Byzantium; 7, Sybaris; 8, Cyrene; 9, Selinus; 10, Metapontum; 11, Megara; 12, Gela. While the majority are the Greek colonies, from Libya to Sicily, from the Euxine to the Adriatic, Greece proper is represented only by Megara and Sicyon. The dates of the foundations cannot be fixed. The Megarian treasury had pedimental figures of gods fighting with giants; others supplemented stonework with painted terra-cotta.

2. The *Philippeum* near the north-west corner of the Altis was dedicated by Philip of Macedon, after his victory at Chaeronea (338 B.C.), illustrating how his position and power enabled him without risking any revolt of Hellenic feeling to erect a monument of the overthrow of Greek freedom in the very heart of the Panhellenic sanctuary. The building had a circular Ionic colonnade about 15 metres in diameter, raised on three steps enclosing a circular cella, with fourteen Corinthian half-columns. It contained portraits by Leochares of Philip, Alexander and other members of their family, in gold and ivory.

3. The *Exedra of Herodes Atticus* at the north limit of the Altis by the N.E. angle of the Heraeum consisted of a half-dome of brick (54 ft. diam.), containing twenty-one marble statues, representing the family of Antoninus Pius, of Marcus Aurelius and of the founder. In front was a drinking trough, its ends adorned by very small temples with circular colonnade.

C. Official Buildings for the management of the sanctuary or the accommodation of guests.

1. Olympia, besides its religious character, originally was the centre of a political amphictyony. So, like a Greek city, it should have a public hearth, where fire should always burn, and where Olympia should exercise hospitality. The *Prytaneum* was at the northwest corner of the Altis, close to the Heraeum. It was a square building containing a chapel of Hestia at the front.

2. The *Porch of Echo,* also called the "Painted Porch," extended 100 yd. along the east Altis wall. A single Doric colonnade, on three steps, open toward the Altis, afforded a place from which to view processions and the sacrifices at the great altar. Built in the Macedonian period, it replaced an earlier portico. In front were pedestals for votive offerings.

3. The *Agora* was that part of the Altis which had the Porch of Echo on the east, the altar of Zeus on the west, the Metroum on the north, and the precinct of the temple of Zeus on the southwest. There stood altars of Zeus Agoraios and Artemis Agoraia.

4. The *Zanes* were bronze images of Zeus, erected out of the fines exacted for breaches of the rules of the contests. They stood at the north side of the Agora, in a row, from the Metroum to the gate of the private entrance into the stadium. Sixteen pedestals were there discovered *in situ.*

REMAINS OUTSIDE THE ALTIS

A. *West Side.*—The wall bounding the Altis of the time of Nero has two gates, at its north and south ends. Each had on the west a portico of four columns. A smaller gate is nearly opposite the Pelopium.

West of this wall, between the Altis and the Cladeus, the following buildings succeed each other from north to south.

1. *The Gymnasium,* a large open space, enclosed on two sides at least by Doric colonnades, on the east by a double portico, more than a stadium in length (220 yd.), served as a racecourse for practice in bad weather. At the southeast corner was a Corinthian doorway, leading to the northwest gate of the Altis. The gymnasium was used by competitors during the last month's training.

2. *The Palaestra,* for wrestlers and boxers, about 70 yd. square, containing rooms of different sizes, and enclosing a building surrounded by a Doric colonnade.

3. *A Byzantine Church* occupies the site of an older brick building, perhaps the "workshop of Pheidias" seen by Pausanias. Among adjacent structures an inscribed altar marks the *Heroum,* where worship of heroes was practised. The *Theocoleon,* a large building of Roman age, was probably the house of the priests. A long narrow building south of the church may have been occupied by those alleged "descendants of Pheidias" (Pausanias v, 14) whose privilege it was to keep the statue of Zeus clean. The so-called "workshop of Pheidias" evidently continued to be used for actual work, and a lodging was required for the artists.

4. *The Leonidaeum,* dedicated by an Elean in the 4th century B.C., for the reception of distinguished visitors. Its orientation is from W.S.W. to E.N.E. An outer Ionic colonnade encloses suites of rooms, around a small interior Doric peristyle. In Roman times it was altered to distribute the rooms into four suites. The porticos show traces of much carriage traffic.

B. *South Side.*—The limits of the Altis toward the Alpheus can only be traced approximately, since architectural changes were numerous down to the latest times.

1. *The Council Hall* (*Bouleuterium*), nearly at the middle of the south wall, comprised two Doric buildings of different date but identical oblong form, divided by a single row of columns, terminating to the west in an apse. In the space between stood a small square building. In front, on the east, a portico covered the front of all three with a large forehall, enclosed by a colonnade.

2. *The South Colonnade,* a late but handsome structure, closed on the north side, with Doric colonnade to southeast and west, and Corinthian columns within, served as a promenade and to view the processions.

3. *A Triumphal Gateway* of Roman age, with triple entrance, opens on the Altis, a little east of the *Bouleuterium.*

C. *East Side.*—The line of the east wall can be followed from the northeast corner of the Altis until it breaks off at the remains known as Nero's house.

1. *Nero's House* is a building of 4th-century date and uncertain purpose, afterward absorbed into a Roman house, to make room for which the south part of the east Altis wall was destroyed. A leaden water pipe bears NER. AVG., and since only a Roman master could have dealt thus with a building within the sacred precinct, it cannot be doubted that the Roman house—from which three doors gave access to the Altis—was that occupied by Nero when he visited Olympia. Later the building, further enlarged, may have been occupied by Roman officials.

2. *The Stadium* extends east of the Altis from W.S.W. to E.N.E., and is entered from the northeast angle. This position was due simply to the curve of the slopes which bound the valley. The stadium is only cleared so far as was necessary for ascertainment of essential points. Low embankments had been built on west, east and south, the north boundary being formed by the natural slope. The space thus defined was about 234 yd. long by 35 broad. There were no artificial seats. From 40,000 to 45,000 spectators could have found sitting room. The exact length of the stadium itself—which was primarily the course for the foot race—was 192.27 m. (about 210 yd.), and consequently the Olympian foot was 0.3204 m. or 1.05 English foot. In the Heraeum, however, the unit adopted was not this Olympian foot, but an older one of 0.297 m., and in the temple of Zeus an Attic foot of 1.08 English foot. The starting point and the goal in the stadium were marked by limestone thresholds. Drainage was by a marginal channel. The stadium was used not only for foot races, but for boxing, wrestling, leaping, quoit throwing and javelin throwing. The entrance from the northeast corner of the Altis was reserved for the judges, competitors and heralds. It was a vaulted tunnel, 100 Olympian feet in length, probably constructed in Roman times. To the west the Altis was entered by a gateway and vestibule.

3. *The Hippodrome,* in which chariot races and horse races were held, can no longer be accurately traced, owing to the overflowings of the Alpheus. But it is clear that it lay south and southeast of the stadium, parallel with it, though stretching beyond it to the east. Its length was probably 770 m. or 4 Olympic stadia.

D. *North Side.*—A wall running east-west immediately north of the treasuries protects them from landslides off the *Hill of Cronus,* and carries the water channel of Herodes Atticus. Further west it is doubtful whether the Altis was ever marked off from the "Hill of Cronus," which is associated with the oldest worship there.

OLYMPIA, the capital city of Washington, U.S.A., and the county seat of Thurston county, at the extreme southern end of Puget sound, 60 mi. S.S W. from Seattle, at the junction of federal highways 99, 101 and 410.

Olympia has a large airport; other transportation is by the Northern Pacific and the Union Pacific railways, motor-coach lines and steamboats.

Pop. (1950) 15,711; (1940) 13,254.

The city occupies 7.9 sq.mi. and is surrounded on the landward sides by low green hills. On the south the DesChutes river flows through a rocky canyon into DesChutes basin, a fresh-water lake that is part of the capitol grounds, with an outlet to Puget sound. The snow-capped Olympics form the northern horizon, and to the east rises Mt. Rainier. On a promontory jutting into the sound stands the group of state buildings, built of white sandstone in classic design at a cost of $17,000,000. The trade of the port of Olympia averages 500,000 tons per year and consists of logs, lumber, plywood, forest products of all types, ores, petroleum products, aluminum and steel products, beverages, military supplies and products from various industries, including canned goods and miscellaneous articles. Olympia is headquarters of the Olympia Na-

tional Forest service.

The first settlement on Puget sound was made in 1845 at the falls of the DesChutes river, on the site of Tumwater, 1 mi. S. of Olympia, under the leadership of Michael T. Simmons from Kentucky, but in 1849 it was practically deserted when the men left for the California gold fields.

In 1850 a town (at first called Smithfield) was laid out where Olympia now stands. In 1852 the first newspaper north of the Columbia river was established there (the *Columbian*) and in 1853 the town became the capital of the newly created territory of Washington.

It was chartered as a city in 1859. A monument in Capitol park marks the terminus of the old Oregon trail.

OLYMPIAD, in Greek chronology, a period of four years, used as a method of dating for literary purposes. The four years were reckoned from one celebration of the Olympic games to another, the first Olympiad beginning with 776 B.C., the last with A.D. 394, when they were abolished during the reign of Theodosius the Great.

The system was first regularly used by the Sicilian historian Timaeus (352–256 B.C.). (*See* CHRONOLOGY.)

OLYMPIAS, daughter of Neoptolemus, king of Epirus, wife of Philip II of Macedon and mother of Alexander the Great. The marriage took place in 359 B.C., shortly after Philip's accession, and Alexander was born in 356. Philip married a new wife, Cleopatra, in 337, and Olympias and Alexander withdrew into Epirus, from which they both returned in the following year, after the assassination of Philip, which Olympias is said to have countenanced. During the absence of Alexander, with whom she regularly corresponded on public as well as domestic affairs, she had great influence, and on Alexander's death in 323 withdrew to Epirus, because of her hostility to Antipater the regent. In 319 she allied herself with Polyperchon, Antipater's successor, and became ruler of Macedonia. Cassander, Antipater's son, hastened from Peloponnesus, and, after an obstinate siege, compelled the surrender of Pydna, where she had taken refuge. One of the terms of the capitulation had been that her life should be spared; but she was brought to trial for the numerous executions which she had ordered during her reign. Condemned without a hearing, she was put to death in 316 by the friends of those she had slain, the promise to spare her life being disregarded.

OLYMPIC GAMES. While the origin of the Olympic games is not known exactly, there is a historical record of the ancient games beginning in 776 B.C. Thereafter they were held at four-year intervals until A.D. 394, when they were abolished by the Roman emperor Theodosius after Greece had lost its independence. Few enterprises created by man have lasted so long. At first the program was confined to one day and consisted only of a single event, a race the length of the stadium. Afterward additional races, the discus throw, the javelin throw, the broad jump, boxing, wrestling, the pentathlon, chariot racing and other events were added, and the duration, including the religious ceremonies, was extended to seven days. The games were restricted to Greeks, but competitors came from all the Greek colonies around the Mediterranean. A sacred truce was declared and enforced to permit participants to travel unmolested to the games. Women were not allowed as competitors or spectators. Before the contests opened all the competitors and their families, the trainers and the judges swore a solemn oath to keep the competition clean and fair and to give just decisions.

The games occupied such an important position in the life of Greece that time was measured by the four-year interval between them—an "Olympiad." The greatest honour then to be attained by any Greek was the winning of the simple branch of wild olive given to a victor in the games. Kings competed alongside commoners; even the Roman emperor Nero sought Olympic honours. Winners became national heroes, musicians sang their praise and sculptors preserved their strength and beauty in marble. Their feats of skill and courage were recorded by the poets and writers of the time. The gracefulness and sportsmanship of the contestant and the method of winning were esteemed equally with the victory itself.

It was through the efforts of the Baron Pierre de Coubertin (1863–1937) of France, a brilliant educator and scholar but not an athlete, that the Olympic games were revived. Having decided that at least one of the reasons for the glory of the Golden Age of Greece was the emphasis placed on physical culture and frequent athletic festivals, he concluded that nothing but good could result if the athletes of all countries of the world were brought together once every four years on the friendly fields of amateur sport, unmindful of national rivalries, jealousies and differences of all kinds and with all considerations of politics, race, religion, wealth and social status eliminated. He summoned an international conference at the Sorbonne, Paris, in 1894, which was attended by the representatives of nine different nations.

The games of the I Olympiad of the modern cycle were held under the royal patronage of the king of Greece in 1896 in a new marble stadium constructed in Athens for the purpose. Subsequent games were held in Paris (1900), St. Louis (1904), London (1908), Stockholm (1912), Antwerp (1920), Paris (1924), Amsterdam (1928), Los Angeles (1932), Berlin (1936), London (1948) and Helsinki (1952). The games of the XVI Olympiad were scheduled for Melbourne, Austr., in 1956. The games of the VI, XII and XIII Olympiads, scheduled, respectively, for Berlin (1916), Tokyo then Helsinki (1940) and London (1944), were not held because of war. In 1906 a set of games was held in Athens, but these were not part of the official series.

A separate cycle of winter games was initiated in 1924 at Chamonix, Fr.; subsequent games were held at St. Moritz (1928), Lake Placid (1932), Garmisch-Partenkirchen (1936), St. Moritz (1948) and Oslo (1952). The VII winter Olympic games were scheduled for Cortina d'Ampezzo, It., in 1956.

The direction of the Olympic movement and the regulation of the games is vested in the Comité International Olympique, with headquarters at Mon Repos, Lausanne, Switz. The committee elects its members for life after a thorough investigation. The C.I.O. is a unique organization in that its members do not represent their countries but are delegates from the committee to their countries. No country may have more than three members. The members must not accept from other organizations or from their governments any instructions that may bind them or interfere with the independence of their votes. In 1952 the committee numbered 72 from 47 different countries. Baron Pierre de Coubertin headed the committee until he retired in 1925. He was followed by Count Henry de Baillet Latour of Belgium, who served until his death in 1942. The next president was J. Sigfrid Edstrom of Sweden, who was succeeded in 1952 by Avery Brundage of the United States.

Contestants in the Olympic games must be amateurs. The Olympic definition is as follows:

> An amateur is one who participates and always has participated in sport solely for pleasure and for the physical, mental or social benefits he derives therefrom, and to whom participation in sport is nothing more than recreation without material gain direct or indirect and in accordance with the rules of the International Federation concerned.

One of the features of the Olympic games introduced successfully for the first time at the Los Angeles games is the Olympic Village. This is special housing provided so that all the competitors from the different countries can live in the same compound.

At the Berlin games in 1936 the sacred Olympic flame, which burns in the stadium throughout the games, was ignited by a torch carried from Olympia, Gr., the site of the ancient games, through the intervening countries by relays of runners. This procedure was repeated at the following games.

The Comité International Olympique awards the following various cups and diplomas annually:

The *Olympic cup* is awarded to an institution or organization for outstanding service to amateur sport or the Olympic movement.

The *Olympic diploma* is awarded for the same reasons to an individual.

The *Taher Pacha cup* is awarded to an athlete who merits special recognition.

The *Fearnley cup* is awarded to an amateur sport club or local association for merit.

The C.I.O. has granted its patronage to certain regional games which contribute to the development of amateur sports in the areas where they are organized. These are the Far Eastern games-Mediterranean games; Asiatic games; Juegos Deportivos Pan Americanos; Juegos Deportivos Bolivarianos; and Juegos Deportivos Centroamericanos y del Caribe.

Participation in the Olympic games is organized by the national Olympic committees, of which 79 were recognized by the C.I.O. in the early 1950s. National Olympic committees must include representatives of all the national governing bodies whose sports are included in the Olympic program. They must be independent and autonomous and must avoid any political, commercial or religious interference. Only national Olympic committees can enter competitors in the games, and they must certify to their amateur standing.

National Olympic committees exist in the following countries: Afghanistan, Argentina, Australia, Austria, Bahamas, Belgium, Bermuda, Bolivia, Brazil, British Guiana, Bulgaria, Burma, Canada, Ceylon, Chile, China, Colombia, Cuba, Czechoslovakia, Denmark, Egypt, El Salvador, Finland, France, Germany, Gold Coast, Great Britain, Greece, Guatemala, Haiti, Hong Kong, Hungary, Iceland, India, Indonesia, Iraq, Iran, Ireland, Israel, Italy, Jamaica, Japan, Korea, Lebanon, Liechtenstein, Luxembourg, Malta, Mexico, Monaco, Netherlands, Netherlands Antilles, New Zealand, Nigeria, Norway, Pakistan, Panamá, Paraguay, Peru, Philippines, Poland, Portugal, Puerto Rico, Rumania, Saar, Singapore, Spain, Sweden, Switzerland, Syria, Thailand, Trinidad, Turkey, Union of South Africa, Union of Soviet Socialist Republics, United States, Uruguay, Venezuela, Vietnam, Yugoslavia.

Each Olympic sport is governed by international federations composed of national federations in each participating country. Competitors must belong to these national federations. The international federations write the rules governing their sports, and the events in the Olympic games are under their direction subject only to the Olympic regulations.

Ceremonies.—The opening ceremony of the games, staged in the principal stadium, is impressive. The king or president of the country where the games are held is received at the entrance of the stadium by the president of the Comité International Olympique and the president of the organizing committee, who escort him to a box where he is greeted with the national anthem of his country. The parade of the competitors then takes place. Each national contingent, dressed in its official uniform, preceded by a shield bearing the name of its country and its national flag, enters the stadium in alphabetical order, except that Greece heads the parade and the organizing country appears last. Each contingent after completing its march around the stadium lines up on the centre of the grounds in a column, behind its shield and flag, facing the tribune of honour. The president of the organizing committee delivers a brief speech of welcome and asks the king or president to proclaim the games open. Immediately a fanfare of trumpets is sounded and the Olympic flag is slowly hoisted; pigeons are released, followed by an artillery salute. At this moment the Olympic flame arrives in the stadium and the sacred fire is lit. A benediction is pronounced and the Olympic hymn is sung. Immediately afterward a contestant from the country where the games are taking place mounts the tribune and pronounces the following oath on behalf of all the assembled athletes:

> We swear that we will take part in the Olympic Games in fair competition, respecting the regulations which govern them and with the desire to participate in the true spirit of sportsmanship for the honour of our country and for the glory of sport.

The choir sings the national anthem and the competitors leave the stadium. The ceremony thus comes to an end and the competitions may begin.

The closing ceremony, equally impressive, is concluded by the president of the C.I.O., who calls the youth of the world to assemble in four years to celebrate the games of the next Olympiad. "May they display cheerfulness and concord so that the Olympic torch may be carried on with ever greater eagerness, courage and honour for the good of humanity throughout the ages." The trumpet sounds, the Olympic fire is extinguished, the Olympic flag is lowered, there is a salute of five guns and the choir sings the final anthem.

National Participation.—In 1896 when the games were revived, interest in competitive sport was largely confined to Great Britain, the United States and the British empire. There was practically no international competition. In the games of the I Olympiad of the modern cycle only a handful of participants from a dozen countries took part. In the games of the XV Olympiad almost 6,000 contestants from 69 different countries participated. Hundreds of journalists, photographers and radio commentators from all over the world travelled to Helsinki to report on the games; public interest in the Olympic movement had spread throughout the entire world. Contestants who placed sixth or better at Helsinki came from 49 different nations, and countries such as Luxembourg, Jamaica, Switzerland, Brazil, Turkey and India produced Olympic champions. Norwegian athletes had made by far the best record in the winter games. Table I shows the growth of participation in the games.

Records.—Because of the increase in the number of competitors, the improved facilities and more scientific coaching, records of performance showed vast improvement. In the 1952 games, in track-and-field athletics alone, 8 new world and 26 new Olympic records were established. Table II lists the Olympic records in track-and-field.

Miscellaneous Facts.—Following are some specific data regarding the Olympic games:

Only nationals can represent a country in the games.

No discrimination is allowed against any country or person on grounds of colour, religion or politics.

There is no age limit for competitors.

No more than three competitors from any country (four in the winter games) may participate in each event.

The games are confined to a period of 16 days.

There is no scoring of points in the games, which are contests between individuals and teams and not between nations.

The honour of holding the games is entrusted to a city and not to a country, and they must be held in the first year of the Olympiad.

Once the Olympic games have been awarded to a city, an organizing committee is formed to provide the facilities and handle

TABLE I.—*Participation in the Olympic Games*

(Official, demonstration and optional sports included)						Winter games (Demonstration events included)

Decathlon	Helsinki	1952	R. Mathias	United States	7,887 points (new scoring table)

all the business arrangements for these festivals.

Any profits derived from the games must be applied for the promotion of the Olympic movement or for the development of amateur sport.

The following events must be included in the program: athletics, gymnastics, boxing, fencing, shooting, wrestling, rowing, swimming, equestrian, modern pentathlon, cycling, weight lifting, yachting, fine arts (architecture, literature, music, painting, sculpture).

The following sports are optional: soccer football, rugby, polo, water polo, grass hockey, handball, basketball, canoeing, gliding.

Only sports practised in at least ten countries (six of which must enter) may be included.

The program for the winter games may include skiing, skating, ice hockey, bobsled, skeleton and curling.

Women are allowed to compete in athletics, fencing, gymnastics, swimming, canoeing, figure skating, skiing, yachting and fine arts.

The Olympic flag has a white background with no border. In the centre are five interlaced rings—blue, yellow, black, green and red, colours which appear on the flags of all countries.

The Olympic motto is "Citius-Altius-Fortius."

The flag and the motto are the exclusive property of the Comité International Olympique and together with the words "Olympic" and "Olympiad" insofar as they refer to sport are protected by law in many countries.

BIBLIOGRAPHY.—A voluminous official report is published by the organizing committee for each set of games. Nearly all national Olympic committees also issue reports. *See* also J. Kieran, *The Story of the Olympic Games, 776 B.C.–1936 A.D.* (1936); F. A. M. Webster, *Olympic Cavalcade* (London, 1948); Ernest A. Bland (ed.), *Olympic Story* (London, 1948); Bill Henry, *Approved History of the Olympic Games* (1948). (Av. BE.)

OLYMPIODORUS, the name of several Greek authors, of whom the chief are:

1. A historical writer (5th century A.D.), born at Thebes in Egypt, who was sent on a mission to Attila by the emperor Honorius in 412 and later lived at the court of Theodosius. He was the author of a history (Ἱστορικοὶ Λόγοι) in 22 books of the western empire from 407 to 425. The original is lost, but an abstract is given by Photius. A manuscript on alchemy ascribed to him and preserved in the National library in Paris was printed with a translation by P. E. M. Berthelot in his *Collection des alchimistes grecs* (1887–88).

2. A Peripatetic philosopher (5th century A.D.), an elder contemporary of Proclus. He lived at Alexandria and lectured on Aristotle with considerable success. His best-known student was Proclus.

3. A Neoplatonist philosopher, also of Alexandria, who flourished in the 6th century A.D., during the reign of Justinian. He was, therefore, a younger contemporary of Damascius and seems to have carried on the Platonic tradition after the closing of the Athenian school in 529, at a time when the old pagan philosophy was at its last ebb.

His philosophy is in close conformity with that of Damascius, and, apart from great lucidity of expression, shows no striking features. He is, however, important as a critic and a commentator, and preserved much that was valuable in the writings of Iamblichus, Damascius and Syrianus.

He made a close and intelligent study of the dialogues of Plato, and his notes, formulated and collected by his pupils (ἀπὸ φωνῆς Ὀλυμπιοδώρου τοῦ μεγάλου φιλοσόφου), are extremely valuable. In one of his commentaries he makes the interesting statement that the Platonic succession had not been interrupted by the numerous confiscations it had suffered. Zeller points out that this refers to the Alexandrian, not to the Athenian, succession; but internal evidence makes it clear that he does not draw a hard line of demarcation between the two schools. The works which have been preserved are a life of Plato, an attack on Strato and Scholia on the *Phaedo, Alcibiades I, Philebus* and *Gorgias*.

See Überweg, *Grundriss der Gesch. der Philosophie,* Bd. I (1926).

OLYMPUS, the name of many mountains in Greece and Asia Minor, and of the fabled home of the gods; also a city name and a personal name.

Of the mountains (1) the most famous is the lofty ridge (mod. Gk. *Elympo*) on the borders of Thessaly and Macedonia; it is nearly 10,000 ft. high and covered with snow for a great part of the year. The great gorge of Tempe close below the southeastern end separates it from Mt. Ossa. Olympus is of massive appearance, rising in precipices broken by ravines, above which is the summit of naked rock concave toward the northwest. The lower parts are densely wooded. (2) The peak of Mt. Lycaeus in the southwest of Arcadia. (3) East of Olympia, on the north bank of the Alpheus. (4) Beside Sellasia in Laconia. The name was even commoner in Asia Minor; it referred to a lofty chain in Mysia (Keshish Dagh) and to a ridge east of Smyrna (Nif Dagh); other mountains in Lycia, in Galatia, in Cilicia and in Cyprus were also all called Olympus.

In the *Iliad* the gods are described as dwelling on a lofty peak, rising high above the clouds of the lower atmosphere into the clear ether; in the *Odyssey* Olympus is more remote and less definite; the notions of later poets vary from a definite mountain to a vague conception of heaven. In literary mythology, though each deity had special haunts, all had residence at the court of Zeus on Olympus; there were their assemblies and feasts.

There was a city in Lycia named Olympus; it was a bishopric in Byzantine times.

OLYNTHUS, an ancient city at the head of the Gulf of Torone, in Chalcidice, near the neck of the peninsula of Pallene, about 60 stadia (7 or 8 mi.) from Potidaea. It may have been a colony of Chalcis, and struck coins early, but the district belonged to a Thracian tribe, the Bottiaeans, who held the town

till 479 B.C., when the Persian general Artabazus, on his return from escorting Xerxes to the Hellespont, suspecting that a revolt from the great king was meditated, slew the inhabitants and handed the town over to Greeks from Chalcidice. Olynthus thus became a Greek *polis*, but it remained insignificant in the lists of the Delian league until 432. King Perdiccas of Macedon added to its population the inhabitants of Chalcidian towns in the neighbourhood (Thucyd. i, 58). Henceforward the chief Hellenic city west of the Strymon, it revolted from Athens, formed a base for Brasidas' expedition (424) and was never again reduced. In the 4th century it was the head of the Chalcidic league which may be traced back to the peace of Nicias (421), when the Chalcidians acted in common and were enrolled as allies of Argos. The motive for its formation is almost certainly to be found in fear of Athens. Coins of the league can be dated as early as 405; one specimen may go back to 415–420. After the Peloponnesian war the league concluded an important treaty, about 390, with Amyntas, king of Macedon (the father of Philip), and by 382 it had absorbed most of the Greek cities west of the Strymon, and even held Pella, the chief city in Macedonia. But in this year Sparta was induced by an embassy from Acanthus and Apollonia, not yet included by the league, to attack; and Olynthus, after three years of indecisive warfare, formally dissolved the confederacy (379). Chalcidians, however, appear among the Athenian naval confederacy of 378–377. Twenty years later, in the reign of Philip, the power of Olynthus is asserted by Demosthenes to have been much greater than before the Spartan expedition, and the league included 32 cities. When war broke out between Philip and Athens (357), Olynthus was at first in alliance with Philip. Subsequently, it concluded an alliance with Athens; but in spite of all the efforts of the Athenians and their orator, Demosthenes, Philip razed it in 348.

OLYPHANT, an anthracite-mining borough of Lackawanna county, Pa., U.S., on the Lackawanna river, 6 mi. N.N.E. of Scranton; served by the Delaware and Hudson railway, and for freight by the New York, Ontario and Western and the Erie railways. Pop. (1950) 7,047; (1940) 9,252 by the federal census.

OMAGH (ō'mah), a market town, urban district and county town of Co. Tyrone, Northern Ireland, on the Strule, 72 mi. W. of Belfast by road. Pop. (1951) 6,762. Area 1.6 sq.mi. The town, picturesquely situated above the river, is a military training centre. Shirts and milk products are the chief manufactures. Local antiquities include the scanty remains of a castle which played a part in the Tudor and Confederation wars.

OMAHA. This Siouan tribe of Nebraska, closely associated with the Ponca, combined agriculture with seasonal buffalo hunting. Since 1829 they have numbered between 1,105 and 1,900. They were organized into moieties and ten patrilineal clans. *See* J. O. Dorsey, *Bur. Am. Ethn. Rep.* xv, (1897); A. C. Fletcher and F. La Flesche, *ibid.* xxvii (1911).

OMAHA, the largest city of Nebraska, U.S.A., a port of entry, and the seat of Douglas county; on the west bank of the Missouri river, 500 mi. W. by S. of Chicago. It is on federal highways 6, 30A, 73, 75 and 275; is served by Mid-Continent and United air lines and by numerous motor bus and truck lines. It has a large municipal airport. Omaha is the nation's fourth largest rail centre, and is served by the Burlington, the Chicago and North Western, the Chicago Great Western, the Chicago Milwaukee, St. Paul and Pacific, the Chicago, St. Paul, Minneapolis and Omaha, the Illinois Central, the Missouri Pacific, the Rock Island, the Union Pacific and the Wabash railways.

The population of Omaha was 251,117 in 1950 and was 223,844 in 1940 and 214,006 in 1930 by the federal census.

Omaha has an altitude ranging from 940 to 1,270 ft. The original town site of 270 blocks, an elongated terrace above the river, is now entirely a business quarter, and gradually the city extended over the hills and bluffs beyond until it covered 41 sq.mi.

The stockyards and packing plants are on the south side (formerly an independent municipality, with a population in 1910 of 26,259), which was annexed in 1915. There are 56 parks, with an aggregate area of 2,500 ac., connected by 125 mi. of boulevard; 31 supervised playgrounds for children; 5 municipal golf courses; and 4 country clubs.

Fontenelle Forest reserve covers 1,800 ac. and is the largest unbroken tract of native forest in the state. Fort Crook (10 mi. S.) and Fort Omaha in the northern part of the city are important military posts. At Fort Crook was constructed a large Martin bomber assembly plant built by the government and operated by the Glenn L. Martin company of Baltimore, Md. Offutt Air Force base is the home of the strategic air command of the U.S. air force.

Among the educational institutions are Nebraska School for the Deaf (1867); the University of Nebraska college of medicine; Creighton university (1878; conducted by the Jesuits), comprising seven colleges and a high school; the University of Omaha (originally a Presbyterian institution, later municipal, founded 1908); and the Presbyterian Theological seminary (1891). Principal newspaper is the *Omaha World-Herald,* formed in 1889. Among the 60 other periodical publications is the *Daily Journal Stockman,* devoted to the livestock industry. Omaha has a community playhouse, a drama club and ten musical organizations. Ak-Sar-Ben (Nebraska spelled backward) is a civic organization, (formed in 1895 to promote interest in the history and progress of the city and the state) which is nationally famous for its livestock shows, horse shows, racing meets, coronation balls, ice hockey and ice revues.

Omaha is the see of Roman Catholic and Protestant Episcopal bishoprics, a district headquarters of the Methodist Church and the Presbyterian Church, and is Baptist state headquarters. There are more than 200 churches and missions in the city, and 11 hospitals. Thirty of the charitable organizations are financed jointly through a Community Chest. The proportion of homes owned by their occupants is high; the percentage of illiteracy is low. Boys Town, site of the internationally famous Father Flanagan's boys' home, is located 11 mi. W. of Omaha. Hundreds of thousands visit the modern farm and plant each year. The home has facilities for 500 boys. Joslyn memorial, a $4,000,000 art museum, is per capita the nation's second most popular art centre.

The city operates under a home-rule charter of 1923, providing for a commission form of government, with elections every three years.

Omaha is the largest retail centre between Chicago and Denver; an important insurance centre, being the location of the home offices of numerous companies and of branches of many others, and one of the leading manufacturing and wholesale distributing centres of the country. It ranks first in the production of butter, and is a primary grain market and milling market and one of the largest general livestock markets and meat-packing centres.

History.—In 1804 Meriwether Lewis and William Clark camped on the Omaha plateau, and in 1825 a licensed Indian trading post was established there. Fur traders and trappers frequented the region through the first half of the 19th century. In 1846 the Mormons settled at "Winter Quarters" (called Florence after 1854, and annexed to Omaha in 1917), but in 1848 they were obliged to move, as it was within the Indian reservation. About 12,000 of them built camps in this vicinity, on both sides of the Missouri, in 1846 and 1847, from which gradually they emigrated to Utah, but their local influence was strong for nearly a decade. Speculative "squatters" intruded on the Indian lands in 1853, and a rush of settlers followed the opening of Nebraska territory in 1854. Omaha (named from the Omaha Indians) was laid out in 1854 and chartered as a city in 1867. Prairie freighting and river traffic were important before the construction of the Union Pacific railroad, which was begun in Dec. 1863. The city was an important outfitting point during the rush to the Colorado gold fields. Connection by telegraph was established with San Francisco in 1861, with Chicago and St. Louis in 1863. The Union Pacific railroad bridge across the Missouri was completed in 1869. The Rock Island, the Burlington and the North Western railways entered the city in 1867 and 1868. Meat packing began as early as 1871, and grew rapidly after 1884, when the

Union Stock Yards company was formed and yards established in South Omaha. In 1860 the population was 1,883; 16,083 in 1870; and 30,518 in 1880. In the next 20 years it increased 236%, and between 1900 and 1920, 87%.

OMAHA BEACHHEAD, the World War II military code name given by the U.S. 5th army corps to a five-mile cliffless section of the Normandy coast at St. Laurent, Fr. It was one of five assault beaches invaded by Allied forces on June 6, 1944.

The U.S. assault troops at Omaha encountered more initial difficulties than the invading U.S. troops on the right flank or the British and Canadian troops on the left flank. Heavy seas and unfavourable surf conditions made navigation of the landing craft difficult, and many men were drowned or reached the beach in a state of near exhaustion. The Allied air attacks had proved ineffective as a result of cloudy weather which obscured visibility, and the configuration of the ground hampered observation for the naval guns. Moreover, it was not possible to manoeuvre the amphibious tanks to provide fire support for the infantry.

The 116th infantry of the 29th division and the 16th infantry of the 1st division encountered the well-prepared German 352nd division and suffered heavy casualties. However, the 5th corps overcame initial difficulties and reached the line of the Bayeux-Carentan road by June 7, and on June 8 contacted the British 50th division on the left flank. Reinforced on June 9 by the U.S. 2nd division, it advanced rapidly to the south and west, reaching the Caumont-Cerisy Forêt-Isigny line by June 11.

On June 12 Carentan fell to U.S. troops. All beachheads were consolidated, and the coast of Normandy was secured by the Allied forces from Quinéville to the east bank of the Orne.

OMAN, SIR CHARLES WILLIAM CHADWICK (1860–1946), British historian, was born at Mozufferpore, India, on Jan. 12, 1860. Educated at Winchester and at New college, Oxford, he was made a fellow of All Souls in 1883. In 1905 he became Chichele professor of modern history at Oxford and he was chosen a fellow of the British academy in the same year. He was president of the Royal Historical society, 1917–21. In 1919 he was elected M.P. for Oxford university and in 1920 he was knighted. His most important work was done in military history. He died June 23, 1946. His works include: *History of the Art of War in the Middle Ages* (1898; new ed., 1924); *History of Greece* (1890); *A Short History of England* (1895; new ed., 1920); *A History of the Peninsular War 1807–13* (7 vol., 1902–30); and *Napoleonic Studies* (1929).

OMAN ('UMĀN), a nominally independent state in southeastern Arabia, extending from Ras Musandam, on the Gulf of Oman, to the eastern limits of Hadhramaut at Ras Sajar (lat. 16° 8″ N.) on the Indian ocean. Inland the state is bounded by the Empty Quarter. The population (1947 est.) 830,000, chiefly Arabs, with a strong Negro element in the coastal regions; the area is about 82,000 sq.mi. The prevailing religion is Ibadi Islam.

Oman is a mountainous district forming part of the ancient land mass of Arabia, granite and limestone rocks being most in evidence. The high ground culminates in Jabal Akhdar (9,900 ft.), which is flanked by steps of the old mountain block down to the coast. The lateral valleys between the steps are often fertile and cultivated, expecially where a good supply of water is available. The wadis, which cut across the mountainous area to the coast, are merely torrential channels, dry for most of the year and often flowing in narrow precipitous gorges, but provide the only ways to the interior. Of these ways, always difficult, the best known are those by the Wadi Qahza, from the port of Matrah; by the Wadi Hail from the port of Quryat; and by the Sama'il valley, leading into the Wadi Munsab from a point 50 mi. N.W. of Muscat. Northwest of Muscat lies the coastal plain known as Al Batinah; it is fertile, prosperous and well populated.

The climate is tropical, with a mean annual rainfall of less than ten inches and a mean annual temperature of 80° F. or more. The vegetation is, however, abundant: tamarisks, oleanders, euphorbias, the milkbush, rhamus and acacias predominate.

Muscat, the capital and the only important harbour, was in Portuguese hands from 1508 to 1648. In 1741 it was taken by Ahmed ibn Sa'id, a descendant of those Yemenite imams who consolidated Arab power in Zanzibar and on the east African coast. His family has ruled Oman ever since. It was the most powerful state in Arabia during the first half of the 19th century, but subsequent raids by the nomadic tribes of the interior, as in 1913–14, and the opportunities for foreign intervention reduced the country for a time to a dependency of India. A treaty of friendship and commerce between Britain and Sultan Sir Sa'id ibn Taimur (succeeded 1932), signed Feb. 5, 1939, reaffirmed the close ties which had existed for nearly 150 years. (*See* ARABIA.)

Date cultivation has reached a high level in the interior. Cereals and vegetables, as well as vines, peaches, apricots, oranges, mangoes and melons, are grown with the dates.

Trade is mainly with India. Dates, promegranates and dried fish are exported, while rice, coffee and cotton goods are the chief imports. Oman's riding camels are considered the best in the world. The little port of Gwadar, on the coast of Baluchistan, the outlet for most of the trade of Makran, is a dependency of Oman.

There are airfields at Salala and on Masira Island, which are staging posts on the routes crossing Africa and the Arabian coast to Karachi. Ships between Karachi and the gulf call weekly at Muscat. Cable communication from Muscat to Jask links Oman with Iran, Iraq and Pakistan.

See Bertram Thomas, *Arab Rule under the Al Bu Sa'id Dynasty of Oman, 1741–1937* (London, 1938).

OMAR (*c.* 581–644), in full 'OMAR IBN AL-KHAṬṬAB, the second of the Mohammedan caliphs (*see* CALIPHATE). Belonging to the clan of 'Adi of the Meccan tribe of Koraish (Quraish), Omar at first opposed Mohammed but later became one of his ablest advisers and on his death secured the election of Abu Bekr as his successor. His own reign (634–644) saw the emergence of Islam as an imperial power. The chief events were the defeat of the forces of the Greek emperor Heraclius on the Yarmuk river (636) and that of the Persians at Kadisiya (637); the settlement of Arab garrisons in Syria and Iraq; the conquest of Egypt by 'Amr ibn el-'As (*q.v.*); and the final rout of the Persians at Nehavend (Nihawand, 641), which opened Iran to Arab rule. Omar also laid down principles for the administration of the conquered lands and helped stabilize the legal practice of Islam. He was a man of strong and ascetic character; his justice and authority were held in universal respect. He was assassinated by a Persian slave in 644. Though he lingered several days after the attack he left the selection of his successor to a council of six of the leading Meccan "Companions of the Prophet." (H. A. R. G.)

OMAR KHAYYAM (GHIYATHUDDIN ABULFATH 'OMAR IBN IBRĀHĪM AL-KHAYYĀMĪ), the great Persian mathematician, astronomer, free thinker and epigrammatist, who derived the epithet Khayyam (the tentmaker) most likely from his father's trade, was born in or near Nishapur, where he is said to have died in A.H. 517 (A.D. 1123). His standard work on algebra, written in Arabic, and other treatises of a similar character raised him at once to the foremost rank among the mathematicians of that age, and induced Sultan Malik-Shah to summon him in A.H. 467 (A.D. 1074) to institute astronomical observations on a larger scale, and to aid him in his great enterprise of a thorough reform of the calendar. The results of Omar's research were a revised edition of the *Zīj* or astronomical tables, and the introduction of the Ta'rikh-i-Malikshahi, or Jalali; that is, the so-called Jalalian or Seljuk era, which commences in A.H. 471 (March 15, A.D. 1079).

Omar's scientific fame, however, is eclipsed in the west by his still greater poetical renown, which he owes to his *rubā'is* (made famous in the west by E. FitzGerald's translation, *The Rubáiyát*) or quatrains, a collection of about 500 epigrams. Although some of his quatrains are purely mystic and pantheistic, most of them bear quite another stamp; they are the breviary of a radical freethinker, who protests in the most forcible manner both against the narrowness, bigotry and uncompromising austerity of the orthodox ulemā and the eccentricity, hypocrisy and ravings of advanced Sūfīs.

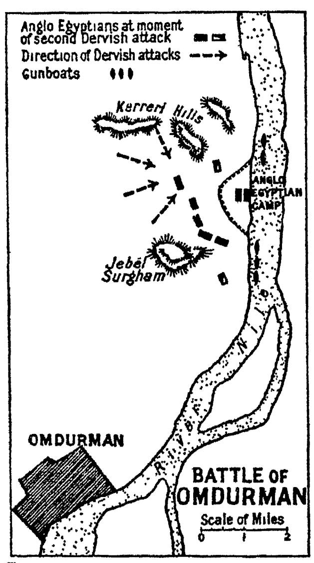
BIBLIOGRAPHY.—The Leyden copy of Omar Khayyām's work on algebra was noticed as far back as 1742 by Gerald Meerman in the preface to his *Specimen calculi fluxionalis;* further notices of the same work by Sédillot appeared in the *Nouv. Jour. As.* (1834) and in vol. xiii of the *Notices et extraits des MSS. de la Bibl. roy.* The complete

text, together with a French translation (on the basis of the Leyden and Paris copies, the latter first discovered by M. Libri, *see* his *Histoire des sciences mathématiques en Italie,* vol. i, p. 300), was edited by F. Woepcke, *L'Algebrè d'Omar Alkhayyāmi* (Paris, 1851). Articles on Omar's life and works are found in Reinaud's *Géographie d'Aboulféda,* pref., p. 101; *Notices et extraits,* vol. ix, p. 143 *et seq.;* Garcin de Tassy, *Note sur les Rubā'iyāt de 'Omar Hhaïyām* (Paris, 1857); Rieu, *Cat. Pers. MSS. in the Br. Mus.,* vol. ii, p. 546; A. Christensen, *Recherches sur les Rubā'iyāt de 'Omar Hayyām* (Heidelberg, 1905); V. Zhukovski, *'Umar Khayyām and the "Wandering" Quatrains,* translated from the Russian by E. D. Ross in the *Journal of the Royal Asiatic Society,* vol. xxx (1898); E. G. Browne, *Literary History of Persia,* vol. ii, p. 246. The quatrains have been edited at Calcutta (1836) and Tehran (1857 and 1862); in English verse, by Edward FitzGerald (London, 1859, 1872 and 1879). FitzGerald's translation has been edited with commentary by H. M. Batson (1900), and the 2nd ed. of the same (1868) by E. Heron Allen (1908). A new English version was published in Trübner's "Oriental" series (1882) by E. H. Whinfield, and the first critical edition of the text, with translations, by the same (1883). Important later works are N. H. Dole's variorum edition (1896), J. Payne's translation (1898), E. Heron Allen's edition (1898) and the *Life* by J. K. M. Shirazi (1905); but the literature in new translations and imitations has recently multiplied exceedingly. *See* A. G. Potter, *A Bibliography of Printed Editions of the Quatrains of Omar Khayyām in Foreign Languages* (1923).

OMBRE, a game of cards, the most fashionable in Europe for many years but now practically obsolete. It has been traced as far back as the 14th century. As late as 1884 Friedrich Anton in a standard manual stated, "Of all games, undoubtedly the most interesting, diversified, and widely known is Ombre." Originally played with the Spanish packs of 40 or 48 cards, it was adapted to the French pack of 52. In the course of time it accreted terms from Spanish, French, Italian and English, as well as a great complexity of rules. Played for the most part by three players, it generated a variant for four, so-called quadrille, which gained great popularity and was one of the five games treated by Edmond Hoyle (1743). A simplification of quadrille, usually called solo, is still played.

BIBLIOGRAPHY.—Henry G. Bohn, "Quadrille," *Handbook of Games* (1850); Friedrich Anton, "L'Hombre," *Encyclopädie der Spiele* (1884).

OMDURMAN. The largest town in the Anglo-Egyptian Sudan, on the west bank of the Nile, opposite Khartoum and immediately north of the junction of the White and Blue Niles. Pop. (1949 est.) 117,650 (87 Europeans). The town covers about 8 sq.mi. Most of the houses are built of mud, but the number of brick houses is increasing. Few buildings survive from the time of the Mahdi. Among these are the Mahdi's tomb, ruined in 1947, the khalifa's house (now a museum), the Beit el Amana, or arsenal (now a football stadium), and part of the old slave market. In the market trade most of the big Sudanese merchants, the chief articles of commerce being hides and gum arabic for export, and imported cotton piece goods. There is also an important camel, sheep and cattle market. Many dwellers in Omdurman are employed in government service in the administrative capital, Khartoum, about 5 mi. distant, to which Omdurman is connected by a bridge over the White Nile. There are many schools, government and private, for both boys and girls. The government maintains a large hospital, and medical and educational work is undertaken by various missionary societies. Local services are controlled by a municipal council composed entirely of Sudanese.



PLAN OF THE BATTLE OF OMDURMAN, SEPT. 2, 1898

Omdurman, then an insignificant village, was chosen in 1884 by the Mahdi Mahommed Ahmed as his capital and so continued after the fall of Khartoum in Jan. 1885. Its growth was rapid, the khalifa (who succeeded the Mahdi) compelling large numbers of disaffected tribesmen to live in the town under the eye of his soldiery. The European captives of the Mahdists—notably Slatin Pasha and Father Ohrwalder—were also imprisoned there. On Sept. 2, 1898, the Anglo-Egyptian army under Lord Kitchener totally defeated the forces of the khalifa at Kerreri, 7 mi. N. of the town. A marble obelisk marks the spot where the 21st Lancers made a charge, in which Winston Churchill took part.

See EGYPT: *Egypt and Sudan Campaigns (1882–1900.)*

(E. H. MH.)

OMEN, a sign in divination, favourable or unfavourable as the case may be (*see* AUGURS; DIVINATION; and ORACLE).

OMICHUND (d. 1767), an Indian whose name is indelibly associated with the treaty negotiated by Robert Clive before the battle of Plassey in 1757. His real name was Amir Chand; and he was not a Bengali, as stated by Thomas Macaulay, but a Sikh from the Punjab. It is impossible now to unravel the intrigues in which he may have been engaged, but some facts about his career can be stated. He had long been a resident of Calcutta, where he had acquired a large fortune by providing the "investment" for the East India company, and also by acting as intermediary between the English and the native court at Murshidabad. Several houses owned by him in Calcutta are mentioned in connection with the fighting that preceded the tragedy of the Black Hole in 1756, and it is on record that he suffered heavy losses at that time. He had been arrested by the English on suspicion of treachery, but afterward he gave help to the fugitives and also valuable advice. On the recapture of Calcutta he was sent by Clive to accompany Watts as agent at Murshidabad. It seems to have been through his influence that the nawab gave reluctant consent to Clive's attack on Chandernagore. Later, when the treaty with Mir Jafar was being negotiated, he put in a claim for 5% of all the treasure to be recovered, under threat of disclosing the plot. To defeat him, two copies of the treaty were drawn up: the one, the true treaty, omitting his claim; the other containing it, to be shown to him, which Adm. Charles Watson refused to sign, but Clive directed the admiral's signature to be appended. When the truth was revealed to Omichund after Plassey, Macaulay states (following Robert Orme) that he sank gradually into idiocy, languished a few months and then died. As a matter of fact, he survived for ten years, till 1767; and by his will he bequeathed £2,000 to the Foundling hospital (where his name may be seen in the list of benefactors as "a black merchant of Calcutta") and also to the Magdalen hospital in London. (J. S. Co.)

OMNIBUS. A term often shortened to "bus," signifying a public passenger-carrying vehicle of large seating capacity. It has become synonymous in popular use with the word "motorbus." Horse-drawn and steam-driven omnibuses have been superseded by motor-propelled omnibuses.

In several particulars an omnibus must conform with regulations laid down by public authorities, especially in connection with dimensions and weights. The carried load, consisting of the passengers and the omnibus body, will at most be less than the regulation weight by a figure termed the chassis weight. The proportion borne by the carried load to the total weight is largely determined by the speed, hill climbing and other performances characteristic of the omnibus and such proportion is always made as large as possible to obtain the maximum earning power. For any specified purpose, designers have in recent years been able to increase this proportion without prejudicing either the reliability of the vehicles or the lowness of their running costs.

Body design aims at making the proportion borne by the passenger load to the carried load as great as possible, and is influenced very greatly by public requirements in the matter of comfort and safety. This proportion tends to become less as more exacting conditions have to be met in the provision of seating, shelter, ventilation and lighting. Passengers may be taken to weigh on an average one-sixteenth of a ton each, but as soon as an omnibus body is provided to carry them, the weight that must be credited to each passenger becomes much greater.

The almost universal practice in omnibus design in 1928 was to employ two axles, the rear wheels being used for driving and braking, and the front wheels being used for steering. The weight

distribution, as indicated by the front and rear axle weights, must be such as to give the adhesion necessary for rapid acceleration and good braking on normal road surfaces. Skidding and inferior performance are the natural consequences of bad weight distribution. The limit is set to front axle weight by the consideration that the driver must be able to turn the front wheels easily in order to steer the vehicle. This limit is reached before the other, which otherwise would affect both axles alike (but which, in consequence of the earlier limit on the front axle, affects the rear axle alone), viz. the limiting axle weight tolerated by local authorities.

Low Centre of Gravity.—In the complete omnibus, under all conditions of loading, the centre of gravity must be so low in relation to the width of the vehicle as to render exceedingly remote the possibilities of over-turning. Where conditions permit, the centre of gravity should occupy a position even lower than that which gives the desired stability. All deviations of a 'bus from uniform motion in a straight line will bring about changes in the loading of every wheel, and these changes become smaller as the centre of gravity approaches the plane of the road. With a low centre of gravity, it will be usual to work very close to the adhesion figures calculated for the stationary omnibus, since the greatest acceleration and braking effects that these figures allow, can be actually approached in practice under all conditions. Where the centre of gravity is high, braking is liable to promote skidding at corners, and on cambered surfaces; rapid acceleration will give rise to the same tendency. Since the carried load in a modern omnibus forms the large proportion of the total weight, and since the carried load comprises very nearly everything which is above floor level, it follows that the problem of making further reductions in the height of the centre of gravity, resolves itself simply into the problem of reducing the floor height.

To obtain the lowest possible floor height, omnibus designers have developed the double reduction driving axle. In this axle, the driving shafts do not transmit the torque direct to the road wheels, but communicate their motion to them through gearing. Each wheel bears a drum coaxial with the brake drum, but of smaller diameter, on which teeth are cut internally. Pinions on the ends of the driving shafts engage with these drums at their lowest points. This arrangement permits the use of full size driving wheels with an axle whose height is considerably less than that of the wheel centres. It permits, moreover, the use of a smaller housing for the right angled drive in the centre of the axle. This drive no longer effects the whole torque multiplication, but only a part of it; whereas the whole multiplication may be nearly 10 to 1, the right angled drive may be called upon to give a multiplication of only 2 to 1, and may therefore be much more compact than one giving the full multiplication.

The centre of gravity is lower in the "N.S." omnibus than in other types. Under the worst conditions, when the upper deck is laden and the lower deck is unladen, the ground may tilt to the extent of 28° beneath the car before over-turning can occur. The best figure obtained with the more usual construction, and without a top cover, was 25°. With the advent of cross seating, omnibus axle weights became so great as to approach the limit tolerated by road authorities. Rear axle weights, reaching that limit, could no longer be increased, and the need arose, as bigger omnibus weights were required, for throwing the weight forward. To this end the forward drive omnibus was introduced in London, and subsequently in all parts of the world.

The modern 'bus body is continued forward to a point only an inch or two behind the rear cylinder block. The driver sits forward alongside the engine, and is actually in a much more favourable position to steer his vehicle round blind corners than formerly. The drawbacks to the forward drive omnibus, are, firstly, the heaviness of steering consequent upon the increased front axle loading, and secondly, the difficulty of access to the engine on the off-side. Neither of these drawbacks has, however, proved serious. There is a tendency among vehicle builders of six wheelers to return to the conventional driving position of many years ago, but the day cannot long be postponed when forward drive will be forced upon designers of six wheelers, as it has been forced upon designers of four wheelers.

Transmission Problem.—Common to all road vehicles employing the internal combustion engine, is the problem of transmitting the power developed by a relatively inflexible prime mover to the road wheels. In the omnibus, above all other vehicles, this problem is one of great difficulty to which no entirely satisfactory solution has yet been found. The high power weight ratio of an ordinary car makes possible the employment of a lightly constructed clutch and gearbox, since the car will normally run in top or direct gear. Only motoring enthusiasts care for driving on the gears and obtaining thereby a splendid performance out of a small capacity engine. Nevertheless, the omnibus driver is called upon to do this, and in consequence, the transmission must be of great robustness and be simple to manipulate. In addition to the need for gear changing, ever present on undulating roads, with the relatively low powered omnibus there is the constant stopping to let down and take up passengers which also calls for gear manipulation. With the very heavy omnibus used in services necessitating a great many stops, it has become impossible to achieve, without high maintenance costs, the propulsion of the load through the agency of the clutch and gearbox. It is probably only a matter of a year or two before other forms of transmission—electric transmission in particular—will live down their many drawbacks, and show on the whole a saving in costs.

For the right angled drive in an omnibus rear axle, bevel, and other forms of gearing have yet to be proved superior to worm gearing. Within recent years, the old fashioned motion communicating screw and wheel has been developed to meet modern automobile and industrial requirements, and in its original form it can scarcely claim a relationship with the highly efficient reversible worm gearing of the present day. The difficulties inherent in the many forms of bevel drive are to make them compact and also silent.

Suspension.—The suspension of an omnibus is effected through longitudinally disposed semi-elliptic leaf springs mounted on the axles, supplemented by rubber buffers, steel volute springs, or other energy absorbing devices over the axles. The latter augment the stiffness of the suspension to meet exceptional load or road conditions.

Rear springs are often allowed to take the driving and braking torque reactions of the rear axle. Where this is not permissible, a torque arm is provided, and the rear springs are shackled at both ends. Tractive effects are often communicated to the vehicle through the rear springs also, though, where a torque arm is provided, the springs must, in view of their being shackled at both ends be relieved of this duty. Where it is provided, the torque arm usually swings from a well braced frame cross-member that has sufficient strength to withstand the pushing and tugging in a horizontal plane to which it will be subjected by the driving and braking exertions of the rear axle. Some vehicles are made with a torque tube surrounding the propeller shaft.

No effort is made by designers to produce completely rigid chassis frames for omnibuses. All things carried on the frame are mounted so as to flex with it or be able to take up a new position without strain. Such rigid structures as engine, gearbox and radiator, are mounted on frame attachments or bearers with rubber or other resilient pads interposing and permitting small relative movements. Where severe conditions must be met, the engine and gearbox are mounted on three such bearers only. Three points of support, however, situated, remain always in a plane, and there can be no distortion from twisting with three point suspension. The drive between units, disposed none too rigidly in relation to one another, is effected by means of shafts bearing flexible couplings or universal joints at their extremities.

The enormous mileages accomplished by the omnibus as compared with the light car, prohibit the adoption by omnibus engineers of light car greasing methods. There is no part of an omnibus which can be packed with grease and left to itself from one year's end to another. Grease nipples and filler caps are provided everywhere in accessible positions, and positive action grease feeding guns which can be relied upon to urge lubricant where

lubrication is necessary, are used under service conditions at frequent intervals.

Tiremakers, anticipating the call for higher omnibus speeds which had been heard for some considerable time, developed the pneumatic tire that would carry heavy loads. With higher running speed, better braking must be provided on all vehicles. Rear wheel adhesion becomes insufficient and all four wheels must be fitted with drums and brake shoes. Four-wheel braking is, in any event, often forced upon designers by the difficulty of accommodating two sets of brake drums on the very small wheel centres that accompany these deep-section tires.

OMRI, an Israelite general, chosen by the army as ruler when, during a campaign against the Philistines, reports came that Zimri, a captain of the chariots, had murdered the king, Elah, in the royal city of Tirzah and proclaimed himself king. Omri promptly marched against Zimri, and captured Tirzah; Zimri, recognizing the hopelessness of his position, set fire to the palace and perished in the flames. A rival party set up Tibni, with whom the Greek versions associate his brother Joram, as king, but Omri defeated this faction and became undisputed king of Israel *c.* 884 B.C. The one deed of his reign recorded in I Kings xvi, 24, is his purchase of the hill of Samaria, upon which he founded a new royal city. But Mesha of Moab mentions him as "having afflicted Moab many days." In spite of the fact that he suffered some reverses at the hand of Syria (I Kings xx, 34), he must have been an accomplished statesman who consolidated his kingdom and made it respected, because for generations after his death Israel is known to the cuneiform writers as "House (or Land) of Omri," and the Israelite Jehu as a "son of Omri." He reigned 12 years and was succeeded by his son Ahab (*q.v.*).

OMSK, a town in the Omsk region of the Russian S.F.S.R., in lat. 55° N., long. 73° 38′ E., on the right bank of the Irtysh, where the Om joins it. It is in the midst of a treeless steppe; violent winds bring snow, often to a depth of six feet, in winter, and sandstorms in summer. Average January temperature 5° F., July 68° F.; annual rainfall 12.4 in.; altitude 285 ft. It is on the trans-Siberian railway, and has a branch linking with Sverdlovsk through Ishim and Tyumen. Steamer routes connect it with the Ob northward along the Irtysh, and southward with the Altai towns and Lake Zaisan, and caravan routes from the Central Asiatic republics and Kazakstan converge upon it. Its population grew from 37,376 in 1897 to 280,716 in 1939, but its appearance is still that of a frontier town, with one-storied wooden huts and unpaved streets, through which Kirghiz ponies and camel caravans thread their way. Stone buildings have been constructed and the cathedral is built of stone; there is a municipal electricity, water and bus service. Its industries include the making of agricultural and other machinery, distilling, brewing, cloth manufacture and foodstuffs, especially sausage. It is a centre for the collection and export of meat, butter, hides and skins. The Russian Geographical society has a museum there and there is much educational and dramatic activity.

A fort was established there in 1716 to protect the Russian settlers from Kirghiz raids. Later, with the increasing colonization of the area and the coming of the railway, the town developed rapidly and became a military centre, with large barracks. After the 1917 revolution, it was the nucleus of Siberian political activity and various governments rapidly succeeded one another; Adm. Alexander Kolchak declared himself dictator of Siberia at Omsk. With the advance of the Bolshevik army, refugees from the west crowded into the town and the insanitary conditions resulted in a plague of spotted fever and typhus. On the capture of the town the refugees fled farther eastward carrying infection with them, though many died of cold, hunger and disease.

ONA, an Indian tribe which once occupied the interior of Tierra del Fuego except the southwestern corner, which was uninhabited, and the southeastern corner, where dwelt a related tribe known as the Haush. The Ona in speech, physique and culture were similar to the giant Tehuelche of Patagonia. They subsisted by hunting and were expert archers. Their chief food was the flesh of the guanaco, a wild camel related to the llama. In addition they ate birds, fish, shellfish, berries and fungi. Ona culture was very primitive. Their dress was a large robe of guanaco fur, moccasins, a petticoat for the women and a fur diadem for the men. In spite of their cold environment they rarely used houses, and habitually slept behind a windbreak of hides. Their manufactures included bows and arrows, short fishing spears, slings, baskets, braided necklaces, wristlets and anklets and a few simple tools. Ona society was organized into hunting groups of relatives. Each group controlled a well-defined territory which it vigorously defended from poachers. As a result blood feuds were common. At times each hunting group assembled to perform initiation ceremonies. Candidates were taught tribal lore, were terrified by masked apparitions and were forced to live in solitude for two years that they might become strong and self-reliant. Ona religion consisted in a fear of certain malevolent spirits and belief in a supreme deity. Ona mythology is rich. The tribe has almost died out.

(S. K. L.)

ONAGRACEAE or OENOTHERACEAE, a family of dicotyledons belonging to the order Myrtiflorae, to which belongs also the myrtle family, Myrtaceae. It contains about 40 genera and 500 species, and occurs chiefly in the temperate zone of the new world, especially on the Pacific side. It is represented in Britain by several species of *Epilobium* (willow herb), *Circaea* (enchanter's nightshade), and *Ludwigia* (false loosestrife), a small perennial herb very rare in boggy pools in Sussex and Hampshire. In the United States, especially in the Pacific states, the family is well represented, the principal genera being *Oenothera* (containing as a native the evening primrose, now naturalized in certain parts of Europe), *Epilobium* and *Ludwigia.* The plants are generally herbaceous, sometimes annual, as species of *Epilobium, Clarkia, Godetia,* or biennial, as *Oenothera biennis*—evening primrose—or sometimes become shrubby or arborescent, as *Fuchsia* (*q.v.*). The simple leaves are generally entire or inconspicuously toothed, and are alternate, opposite or whorled in arrangement; they are generally exstipulate. The flowers are often solitary in the leaf axils, as in many species of *Fuchsia, Clarkia,* etc., or associated, as in *Epilobium* and *Oenothera,* in large showy terminal spikes or racemes; in *Circaea* the small white or red flowers are borne in terminal and lateral racemes. The regular flowers have the parts in fours, the typical arrangement as illustrated by *Epilobium, Oenothera* and *Fuchsia* being as follows: four sepals, four petals, two alternating whorls of four stamens, and four inferior carpels. The floral receptacle is produced above the ovary into the so-called calyx tube, which is often petaloid, as in *Fuchsia,* and is sharply distinguished from the ovary, from which it separates after flowering.

GREAT HAIRY WILLOW HERB (EPILOBIUM HIRSUTUM)

In *Clarkia* the inner whorl of stamens is often barren, and in *Eucharidium* it is absent. In *Circaea* the flower has its parts in twos. Both sepals and petals are free; the former are valvate in bud, and reflexed in the flower; in *Fuchsia* they are petaloid. The petals are generally convolute in bud; they are entire (*Fuchsia*) or bilobed (*Epilobium*); in some species of *Fuchsia* they are small and scalelike, or absent (*F. apetala*). The stamens are free, and those of the inner whorl are generally shorter than those of the outer whorl. The flowers of *Lopezia* (Central

America) have only one fertile stamen. The large spherical pollen grains are connected by viscid threads. The typically quadrilocular ovary contains numerous ovules on axile placentas; the one- to two-celled ovary of *Circaea* has a single ovule in each loculus. The long slender style has a capitate (*Fuchsia*), four-rayed (*Oenothera, Epilobium*) or four-notched (*Circaea*) stigma. The flowers, which have generally an attractive corolla and honey secreted by a swollen disk at the base of the style or on the lower part of the calyx tube, are adapted for pollination by insects, chiefly bees and lepidoptera; sometimes by night-flying insects when the flowers are pale and open toward evening, as in evening primrose. The fruit is generally a capsule splitting into four valves and leaving a central column on which the seeds are borne as in *Epilobium* and *Oenothera*—in the former the seeds are scattered by aid of a long tuft of silky hairs on the broader end. In *Fuchsia* the fruit is a berry, which is sometimes edible, and in *Circaea* a nutlet bearing recurved bristles. The seeds are exalbuminous. Several of the genera are well-known as garden plants; *e.g., Fuchsia, Oenothera, Clarkia* and *Godetia.* Evening primrose (*Oenothera biennis*), a native of North America, occurs apparently wild as a garden escape in Britain. *Jussieua,* a tropical genus of 50 species of water and marsh herbs, shows a development of well-developed aerating tissue in certain species.

ONATAS, a Greek sculptor of the time of the Persian wars, a member of the flourishing school of Aegina. Many of his works are mentioned by Pausanias; they included a Hermes carrying the ram, and a strange image of the Black Demeter made for the people of Phigaleia; also some groups in bronze at Olympia and Delphi, including a bronze chariot for Hieron I of Syracuse. From Pausanias' descriptions we may assume that the figures on the pediments of Aegina represent his style. They are manly, vigorous, athletic, showing great knowledge of the human form, but somewhat stiff and automatonlike.

ONCOSTS: *see* OVERHEAD CHARGES.

ONEGA (ŏn′e-gah), the largest lake in Europe next to Ladoga, area, 3,764 sq.mi. and coast line 870 mi. in length. It lies mostly in the Karelian A.S.S.R., though its southern portion is in the province of Leningrad. The lake basin extends northwest and southeast, the direction characteristic of the lakes of Finland and the line of glacier-scoring observed in that region. The southern coast is comparatively regular and has few islands, but the north is broken into inlets, the largest being Povyenets bay, and is crowded with islands (*e.g.,* Klimetsk) and submerged rocks. The northwestern shore between Petrozavodsk and the mouth of the river Lumbosha consists of dark clay slates, generally arranged in horizontal strata and broken by protruding, parallel ridges of diorite, which extend far into the lake. The eastern shore, as far as the mouth of the Andoma, is for the most part alluvial, with outcroppings of red granite and in one place (the mouth of the Pyalma) diorite and dolomite. To the southeast are sedimentary Devonian rocks, and the general level of the coast is broken by Mt. Andoma and Cape Petropavlovskiy (160 ft. above the lake); to the southwest a quartz sandstone (used as a building and monumental stone in Leningrad) forms a fairly bold rim. Lake Onega lies 125 ft. above the sea. The greatest depths, 318 to 408 ft., occur at the entrance to the double bay of Lizhemsk and Unitsk. On the continuation of this line the depth exceeds 240 ft. in several places. In the middle of the lake the depth is 120 to 282 ft., and less than 120 ft. in the south. The lake is 145 mi. long, with a maximum breadth of 45 mi. The most important affluents, the Vodka, the Andoma and the Vytegra, come from the east. The Kumsa, a northern tributary, is sometimes represented as if it connected the lake with Lake Seg, but at the present time the latter drains to the White sea. The Onega canal (45 mi. long) was constructed in 1818–51 along the southern shore in order to connect the Svir (and hence Lake Ladoga and the Baltic) with the Vytegra, which connects with the Volga. In 1928 an electric station was constructed on the Svir river. Lake Onega remains free from ice for 209 days in the year (middle of May to second week of December). The water is at its lowest level in the beginning of March; by June it has risen two ft. A considerable population is scattered along the shores of the lake, mainly occupied in the timber trade, fisheries and mining industries. The opening of the Murmansk railway along the western shore in 1917 developed settlement. Salmon, *palya* (a kind of trout), burbot, pike, pike perch and perch are among the fish caught in the lake.

The Onega river rises in Lake Vozhe, and is navigable for boats and rafts from Kargopol to the Gulf of Onega, an inlet of the White sea. It flows through the provinces of Vologda and Archangel and has no connection with Lake Onega. At the mouth of this river (on the right bank) in 63° 55′ N., 38° 55′ E., in the province of Archangel, stands the town and port of Onega. Pop. (1926) 5,254. It dates from settlements made by the people of Novgorod in the 15th century, known in history as Ustenskaya or Ustyanskaya. It has a sawmilling industry, and has summer steamer routes to Soroka, Kem and Archangel, but the season is short because of the persistence of land floes and loose pack. Telegraphic communication is by the Archangel railway.

ONEIDA, the only city of Madison county, New York, U.S., on Oneida creek, 6 mi. S.E. of Oneida lake, midway between Utica and Syracuse. It is served by the New York Central and the New York, Ontario and Western railways. Pop. (1950) 11,367; 10,291 in 1940. Adjoining Oneida on the west is the village of Wampsville, the county seat. Across the creek, to the southeast, is the village of Oneida Castle, formerly the gathering place of the Oneida Indians. Oneida is the headquarters of the Oneida community (*q.v.*), which controls important industries (notably the manufacture of silver-plated ware) there and elsewhere. The city also manufactures caskets and furniture, chucks and bottle caps, silverware cases, milking machines, pole line hardware, electric transmission equipment, gray iron castings, bandages, paper boxes and memorials. Oneida was founded by Sands Higginbotham, who bought the site in 1829–30. It was incorporated as a village in 1848 and as a city in 1901.

ONEIDA (a corruption of their proper name *Oneyotka-ono,* "people of the stone," in allusion to the Oneida stone, a granite boulder near their former village, which was held sacred by them), a tribe of North American Indians of Iroquoian stock, forming one of the Six Nations. They lived around Oneida lake in New York state, in the region southward to the Susquehanna. They were not loyal to the league's policy of friendliness to the English, but inclined toward the French, and were practically the only Iroquois who fought for the Americans in the War of Independence. As a consequence they were attacked by others of the Iroquois under Joseph Brant and took refuge within the American settlements till the war ended, when the majority returned to their former home, while some migrated to the Thames river district, Ontario. Early in the 19th century they sold their lands, and most of them settled on a reservation at Green Bay, Wis., a few remaining in New York state. In 1926 the Oneidas in the United States numbered 3,238 persons, of whom 2,976 were in Wisconsin and 262 in New York state. They are civilized and prosperous. *See* NORTH AMERICA: *Ethnology.*

ONEIDA COMMUNITY, a U.S. communistic society at Oneida, N.Y. It was founded at Putney, Vt., in 1842, by John Humphrey Noyes (1811–86), a graduate of Dartmouth college. "Converted" at a revival, he entered Yale Theological seminary. Bible studies convinced him that Christ came a second time in 70 A.D. and absolved Christians from necessity of sin. Called a perfectionist, he barely escaped expulsion from the seminary before graduation, and later was deprived of his licence as a Congregational minister. He and his followers established a commune, eventually pooling all property, renouncing all religious observances and instituting "complex marriage." Monogamy was antagonistic to their ideals. In 1847, dissension having brought them before the courts and their theories and practices before the public, they were forced to leave Putney. They purchased, near Oneida, N.Y., 600 ac. of forestland which proved extremely productive. They planted orchards, lumbered, blacksmithed, farmed and made steel traps—their most profitable industry. In Jan. 1847 their first annual inventory revealed them to be worth about $67,000.

They were mostly New England farmers and mechanics. They had the reputation of being excellent citizens only remarkable for

their earnest interest in eugenics. They sought to make practical application of what scientific information they possessed endeavouring by change and experiment to produce the best possible offspring.

Owing to increasing pressure of public sentiment, which had been anticipated though for 25 years it was unexpressed, Noyes, with a few adherents, removed to Canada in 1880 and the community at Oneida voluntarily dissolved as a communistic experiment and formed a stock company known as the Oneida Community, Limited. At that time it manufactured sewing and embroidery silk, steel traps and silverware, and canned large quantities of fruits and vegetables, but has gradually confined itself to the manufacturing of silverware. The present company has "no connection with the old beyond the personnel and traditions which it inherited from its 40 years' experience as a community."

Among the chief writings of J. H. Noyes dealing with the origin, principles and history of the Oneida Community are *The Berean* (1847), a manual for the use of members; *Salvation from Sin the End of Christian Faith* (1869); *History of American Socialisms* (1870); *Home-Talks* (1875); *Essay on Scientific Propagation* (c. 1875). *See* also *Bible Communism* (1853), a compilation of the community's theories; George Noyes, comp. and ed., *Religious Experiences of John Humphrey Noyes* (1923); Robert A. Parker, *A Yankee Saint* (1935); Pierrepont B. Noyes, *My Father's House* (1937). (P. B. N.)

O'NEILL, the name of an Irish family descended from Niall, king of Ireland in the 5th century, and known as Niall of the Nine Hostages. He is said to have made war against rulers in Ireland, Britain and Gaul, stories of his exploits being related in the *Book of Leinster* and the *Book of Ballymote.* This king had 14 sons, one of whom was Eoghan (Owen), from whom the O'Neills were descended. The descendants of Niall were divided into two main branches, the northern and the southern Hy Neill, to one or other of which nearly all the high-kings (ard-ri) of Ireland from the 5th to the 12th century belonged; the descendants of Eoghan being the chief of the northern Hy Niell[1]. Eoghan was grandfather of Murkertagh (Muircheartach) (d. 533), said to have been the first Christian king of Ireland, whose mother, Eirc or Erca, became by a subsequent marriage the grandmother of St. Columba. Of this monarch, known as Murkertagh MacNeill (Niall), and sometimes by reference to his mother as Murkertagh Mac Erca, the story is told, illustrating an ancient Celtic custom, that he emphasized the inviolability of a treaty with a tribe in Meath by having it written with the blood of both clans mixed in one vessel. Murkertagh was chief of the great north Irish clan, the Cinel Eoghain, and after becoming king of Ireland in 517, he seized a tract in the modern Co. Derry, which remained till the 17th century in the possession of the Cinel Eoghain. The inauguration stone of the Irish kings, the Lia Fail, or Stone of Destiny, fabled to have been the pillow of the patriarch Jacob when he dreamed of the heavenly ladder, was said to have been presented by Murkertagh to the king of Dalriada, by whom it was conveyed to Dunstaffnage castle in Scotland. (*See* SCONE.) A lineal descendant of Murkertagh was Niall Frassach (*i.e.*, of the showers), who became king of Ireland in 763. His grandson, Niall (791–845), drove back the Vikings who began to infest the coast of Donegal. Niall's son, Aedh (Hugh) Finnlaith, was father of Niall Glundubh (*i.e.*, Niall of the black knee), one of the most famous of the early Irish kings, from whom the family surname of the O'Neills was derived. His brother Domhnall (Donnell) was king of Ailech, a district in Donegal and Derry; the ruined masonry of the royal palace is still to be seen on a hill overlooking loughs Foyle and Swilly. On the death of Domhnall in 911 Niall Glundubh became king of Ailech, and, after defeating the kings of Dalriada and Ulidia he became king of Ireland in 915. To him is attributed the revival of the ancient meeting of Irish clans known as the Fair of Telltown. He fought many battles against the Norsemen, in one of which he was killed in 919 at Kilmashoge, where his place of burial is still to be seen.

His son Murkertagh, who gained a victory over the Norse in 926, is celebrated for his triumphant march round Ireland, the *Moirthimchell Eiream,* when he captured many kings and chieftains. From the dress of his followers in this expedition he was called "Murkertagh of the Leather Cloaks." The exploit was celebrated by Cormacan, the king's bard, and a number of Murkertagh's other exploits are related in the *Book of Leinster.* He was killed in battle against the Norse in 943, and was succeeded as king of Ailech by his son, Donnell Ua Niall (*i.e.,* O'Neill, grandson of Neill, or Niall, the name O'Neill becoming about this time an hereditary family surname), whose grandson, Flaherty, made a pilgrimage to Rome in 1030.

Aedh (Hugh) O'Neill, chief of the Cinel Eoghain, or lord of Tir-Eoghain (Tir-Owen, Tyrone) at the end of the 12th century, came into conflict with the Anglo-Norman monarchy, whose pretensions he disputed in Ulster. His son (or nephew), Hugh O'Neill, lord of Tyrone, was styled "Head of the liberality and valour of the Irish." Hugh's son, Brian, was inaugurated prince, or lord, of Tyrone in 1291; and his son Henry became lord of the *Clann Aodha Buidhe* (Clanaboy or Clandeboye) early in the 14th century. Henry's son Murkertagh the Strongminded, and his great-grandson Hugh, greatly consolidated the power of the O'Neills. Niall Og O'Neill, one of the four kings of Ireland, accepted knighthood from Richard II.; and his son Eoghan formally acknowledged the supremacy of the English crown, though he afterwards ravaged the Pale, and was inaugurated "the O'Neill" (*i.e.,* chief of the clan) on the death of his kinsman Domhnall Boy O'Neill. He was deposed (1455) by his son Henry, who in 1463 was acknowledged as chief of the Irish kings by Henry VII. Contemporary with him was Neill Mor O'Neill, lord of Clanaboy. From Neill Mor O'Neill's son Brian was descended the branch of the O'Neills who, settling in Portugal in the 18th century, became Portuguese nobles. This branch represents the male line of the ancient Irish kings of the house of O'Neill.

CONN O'NEILL (*c.* 1480–1559), 1st earl of Tyrone, surnamed Bacach (the Lame), grandson of Henry O'Neill mentioned above, was the first of the O'Neills to come to the front as a leader of the Irish against the English in the 16th century. Conn became chief of the Tyrone branch of the O'Neills (Cinel Eoghain) about 1520. Tyrone having been invaded in 1541 by Sir Anthony St. Leger, the lord deputy, Conn delivered up his son as a hostage, attended a parliament held at Trim, and, crossing to England, made his submission at Greenwich to Henry VIII., who created him earl of Tyrone for life. He was also made a privy councillor in Ireland, and received a grant of lands within the Pale. O'Neill's submission to the English king, and his acceptance of an English title were resented by his clansmen and dependents. The earl maintained a feud with his son Shane (John), arising out of his transaction with Henry VIII. The nomination of O'Neill's reputed son Matthew as his heir with the title of baron of Dungannon by the English king conflicted with the Irish custom of tanistry (*q.v.*), which regulated the chieftainship of the Irish clans; moreover, Matthew, if indeed he was O'Neill's son at all, was illegitimate, and Shane, Conn's eldest legitimate son, would not permit any invasion of his rights. The fierce family feud ended in the murder of Matthew by agents of Shane in 1558; Conn dying about a year later. Conn was twice married, Shane being the son of his first wife, a daughter of Hugh Boy O'Neill of Clanaboy. An illegitimate daughter of Conn married the celebrated Sorley Boy MacDonnell (*q.v.*).

SHANE O'NEILL (*c.* 1530–1567), rejected overtures from the earl of Sussex, the lord deputy, and refused to help the English against the Scottish settlers on the coast of Antrim, allying himself instead with the MacDonnells, the most powerful of these immigrants. Nevertheless Queen Elizabeth was disposed to come to terms with Shane, who after his father's death was *de facto* chief of the O'Neill clan. She recognized his claims to the chieftainship, thus throwing over Brian O'Neill, son of the murdered Matthew, baron of Dungannon, on terms. O'Neill, however, refused to put himself in the power of Sussex without a guarantee for his safety; and his claims were so exacting that Elizabeth determined to restore Brian. An attempt to incite the O'Donnells against him was frustrated by Shane's capture of Calvagh O'Donnell, whom he

[1]A list of these kings will be found in P. W. Joyce's *A Social History of Ancient Ireland* (London, 1903), vol. i., pp. 70, 71.

kept a prisoner for nearly three years.

Elizabeth, who was not prepared to undertake the subjugation of the Irish chieftain, urgently desired peace with him, especially when the devastation of his territory by Sussex brought him no nearer to submission. Sussex was not supported by the queen, who sent the earl of Kildare to arrange terms with O'Neill. The latter agreed to present himself before Elizabeth. Accompanied by Ormonde and Kildare he reached London on Jan. 4, 1562. Elizabeth temporized; but finding that O'Neill was in danger of becoming a tool in the hands of Spanish intriguers, she permitted him to return to Ireland, recognizing him as "the O'Neill," and chieftain of Tyrone; though a reservation was made of the rights of Hugh O'Neill, who had succeeded his brother Brian as baron of Dungannon, Brian having been murdered in April 1562 by his kinsman Turlough Luineach O'Neill.

There were at this time three powerful contemporary members of the O'Neill family in Ireland—Shane, Turlough and Hugh, 2nd earl of Tyrone. Turlough had been elected tanist (*see* Tanistry) when his cousin Shane was inaugurated the O'Neill, and he schemed to supplant him during Shane's absence in London. The feud did not long survive Shane's return to Ireland, where he reestablished his authority and renewed his turbulent tribal warfare. Elizabeth at last authorized Sussex to take the field against Shane, but two expeditions failed. Shane then laid the whole blame for his lawless conduct on the lord deputy's repeated alleged attempts on his life. Elizabeth consented to treat, and practically all O'Neill's demands were conceded. O'Neill then turned his hand against the MacDonnells, claiming that he was serving the queen of England in harrying the Scots. He fought an indecisive battle with Sorley Boy MacDonnell near Coleraine in 1564, and in 1565 routed the MacDonnells and took Sorley Boy prisoner near Ballycastle. This victory strengthened Shane O'Neill's position, and preparations were made for his subjugation. O'Neill ravaged the Pale, failed in an attempt on Dundalk, made a truce with the MacDonnells and sought help from the earl of Desmond. The English, on the other hand, invaded Donegal and restored O'Donnell. O'Neill was routed by the O'Donnells at Letterkenny; and seeking safety in flight, he threw himself on the mercy of his enemies, the MacDonnells. Attended by a small body of galloglasses, and taking his prisoner Sorley Boy with him, he presented himself among the MacDonnells near Cushendun, on the Antrim coast. There, on June 2, 1567, he was slain by the MacDonnells.

Turlough Luineach O'Neill (*c.* 1530–95), earl of Clanconnell, was inaugurated chief of Tyrone on Shane's death. He sought to strengthen his position by alliance with the O'Donnells, MacDonnells and MacQuillans. An expedition under the earl of Essex was sent against him, which effected little, and by treaty in 1575 O'Neill received extensive grants of land and permission to employ 300 Scottish mercenaries. In 1578 he was created baron of Clogher and earl of Clanconnell for life; but for the next few years he continued to intrigue against the English authorities. The latter, as a counterpoise to Turlough, supported his cousin Hugh, brother of Brian, whom Turlough had murdered. Eventually Turlough resigned the headship of the clan in favour of Hugh, who was inaugurated the O'Neill in 1593. Turlough died in 1595.

Hugh O'Neill (*c.* 1540–1616), 2nd earl (known as the great earl) of Tyrone, was the second son of Matthew, reputed illegitimate son of Conn, 1st earl of Tyrone. He succeeded his brother Brian when the latter was murdered by Turlough in 1562, as baron of Dungannon. He was brought up in London, but returned to Ireland in 1567 after the death of Shane, under the protection of Sir Henry Sidney. He served with the English against the 15th earl of Desmond in Munster in 1580, and assisted Sir John Perrot against the Scots of Ulster in 1584. In the following year he attended parliament as earl of Tyrone, though Conn's title had been for life only, and had not been assumed by Brian. Hugh's constant disputes with Turlough were fomented by the English, but after Hugh's inauguration as the O'Neill on Turlough's resignation in 1593, he was supreme in the north. Having roused the ire of Sir Henry Bagnal (or Bagenal) by eloping with his sister in 1591, he afterward assisted him in defeating Hugh Maguire at Belleek in 1593; and then again went into opposition and sought aid from Spain and Scotland. Sir John Norris was ordered to Ireland to subdue him in 1595, but Tyrone took the Blackwater fort and Sligo castle before Norris was prepared; he was thereupon proclaimed a traitor of Dundalk. In spite of the traditional enmity between the O'Neills and the O'Donnells, Tyrone allied himself with Hugh Roe O'Donnell, nephew of Shane's former enemy Calvagh O'Donnell, and the two chieftains opened communications with Philip II of Spain, their letters to whom were intercepted by the viceroy, Sir William Russell. They presented themselves as champions of the Catholic religion, claiming religious and political liberty for the Irish. In April 1596 Tyrone received promises of help from Spain. He temporized successfully for more than two years, making professions of loyalty which deceived Sir John Norris and the earl of Ormonde. In 1598 a formal pardon was granted to Tyrone by Elizabeth. Within two months he was again in the field, and on Aug. 14 he destroyed an English force under Bagnal at the Yellow ford on the Blackwater. If the earl had known how to profit by this victory, he might then have successfully withstood the English power in Ireland; for in every part of Ireland—and especially in the south, where James Fitzthomas Fitzgerald, with O'Neill's support, was asserting his claim to the earldom of Desmond at the head of the Geraldine clansmen—discontent broke into flame. But Tyrone procrastinated. Eight months after the battle of the Yellow ford, the earl of Essex landed in Ireland. He met Tyrone at a ford on the Lagan on Sept. 7, 1599, when a truce was arranged; but Elizabeth objected to the conditions allowed to the O'Neill and to Essex's treatment of him as an equal. Tyrone then issued a manifesto to the Catholics of Ireland summoning them to join his standard. After an inconclusive campaign in Munster in Jan. 1600, he returned to Donegal where he received supplies from Spain and a token of encouragement from Pope Clement VIII. In May of the same year armies under Sir Henry Docwra and Lord Mountjoy (later earl of Devonshire) compelled O'Neill to retire to Armagh, a large reward having been offered for his capture alive or dead.

The appearance of a Spanish force at Kinsale drew Mountjoy to Munster in 1601; Tyrone followed him, and at Bandon joined forces with O'Donnell and with the Spaniards under Don John d'Aquila. The attack failed. O'Donnell went to Spain, where he died, and Tyrone with a shattered force went to the north, where he renewed his temporizing policy. Early in 1603 Elizabeth instructed Mountjoy to open negotiations; and in March Tyrone, in ignorance of Elizabeth's death, made his submission. In Dublin he heard of the accession of King James, at whose court he presented himself in June accompanied by Rory O'Donnell, who had become chief of the O'Donnells after the departure of his brother Hugh Roe. James confirmed Tyrone in his title and estates, but new disputes arose on his rights over certain of his feudatories, of whom Donnal O'Cahan was the most important. This dispute dragged on until 1607, when Tyrone arranged to go to London to submit the matter to the king. Warned, however, that his arrest was imminent, and possibly persuaded by Rory O'Donnell (created earl of Tyrconnel in 1603), Tyrone resolved to fly from the country.

"The flight of the earls," one of the most celebrated episodes in Irish history, occurred on Sept. 14, 1607, when Tyrone and Tyrconnel embarked at midnight at Rathmullen on Lough Swilly, with their wives, families and retainers numbering 99, and sailed for Spain. Driven by contrary winds to take shelter in the Seine, the refugees passed the winter in the Netherlands, and in 1608 went to Rome, where they were entertained by Pope Paul V, and where Tyrconnel died the same year. In 1613 Tyrone was outlawed and attainted by the Irish parliament, and he died in Rome on July 20, 1616. He was four times married, and had a large number both of legitimate and illegitimate children.

Sir Phelim O'Neill (*c.* 1603–53), a kinsman and younger contemporary of the earl of Tyrone, took a prominent part in the rebellion of 1641. In that year he was elected member of the Irish parliament for Dungannon, and joined the earl of Antrim and other lords in supporting Charles I against the parliament. On Oct. 22, 1641, he surprised and captured Charlemont castle; and having been chosen commander in chief of the Irish in the north,

he forged and issued a pretended commission from Charles I sanctioning his proceedings. Phelim and his followers ravaged Ulster on the pretext of reducing the Scots, but failed to take Drogheda, being compelled by the duke of Ormonde to raise the siege in April 1642. During the summer his fortunes ebbed, and he was superseded by his kinsman Owen Roe O'Neill.

Owen Roe O'Neill (*c.* 1590–1649), one of the most celebrated of the O'Neills, the subject of the well-known ballad "The Lament for Owen Roe," was the son of Art O'Neill, a younger brother of Hugh, 2nd earl of Tyrone. Having served with distinction in the Spanish army, he was immediately recognized on his return to Ireland as the leading representative of the O'Neills. Phelim resigned the northern command in his favour, and escorted him from Lough Swilly to Charlemont. But jealousy between the kinsmen was complicated by differences between Owen Roe and the Catholic council which met at Kilkenny in 1642. Owen Roe's real aim was the complete independence of Ireland, while the Anglo-Norman Catholics represented by the council desired to secure religious liberty and an Irish constitution under the English crown. In 1646 a cessation of hostilities was arranged between Ormonde and the Catholics; and O'Neill, furnished with supplies by the papal nuncio Giovanni Rinuccini, turned against the Scottish parliamentary army under General Monro. On June 5, 1646, O'Neill routed Monro at Benburb, on the Blackwater; but, being summoned to the south by Rinuccini, he had to leave Monro unmolested at Carrickfergus. For the next two years confusion reigned, O'Neill supporting the party led by Rinuccini, though continuing to profess loyalty to Ormonde as the king of England's representative. Isolated by the departure of the papal nuncio from Ireland in 1649, he made overtures to Ormonde, and to George Monk (later duke of Albemarle), who had superseded Monro in command of the parliamentarians in the north. O'Neill's chief need was supplies, and failing to obtain them from Monk he turned once more to Ormonde and the Catholic confederates, with whom he prepared to co-operate more earnestly when Oliver Cromwell's arrival in Ireland in Aug. 1649 brought the Catholic party face to face with serious danger. Before anything was accomplished by this combination, however, Owen Roe died on Nov. 6, 1649.

The alliance between Owen Roe and Ormonde had been opposed by Phelim O'Neill, who after his kinsman's death expected to be restored to his former command. In this he was disappointed; but he continued to fight against the parliamentarians until 1652, when a reward was offered for his apprehension. Betrayed by a kinsman while hiding in Tyrone, he was tried for high treason, and executed on March 10, 1653. Phelim married a daughter of the marquis of Huntly, by whom he had a son, Gordon O'Neill, who was member of parliament for Tyrone in 1689; fought for the king at the siege of Derry and at the battles of Aughrim and the Boyne; and afterward commanded an Irish regiment in the French service, and died in 1704.

Daniel O'Neill (*c.* 1612–64), a member of the Clanaboy branch of the family, spent much of his early life at the court of Charles I, and became a Protestant. He commanded a troop of horse in Scotland in 1639; was involved in army plots in 1641, for which he was committed to the Tower, but escaped; and on the outbreak of the Civil War returned to England and served with Prince Rupert, being present at Marston moor, the second battle of Newbury and Naseby. He then went to Ireland to negotiate between Ormonde and his uncle, Owen Roe O'Neill. He was made a major general in 1649, and but for his Protestantism would have succeeded Owen Roe as chief of the O'Neills. He joined Charles II at The Hague, and took part in the expedition to Scotland and the Scottish invasion of England in 1652.

Hugh O'Neill (d. *c.* 1660), son of Owen Roe's brother, Art Oge, and therefore known as Hugh Mac Art, had served with distinction in Spain before he accompanied his uncle, Owen Roe, to Ireland in 1642. After the death of Owen he defended Clonmel in 1650 against Cromwell, on whom he inflicted the latter's most severe defeat in Ireland. In 1647 he so stubbornly resisted Henry Ireton's attack on Limerick that he was excepted from the benefit of the capitulation, and, after being condemned to death and reprieved, was sent as a prisoner to the Tower. He was released in 1652, and died, some time after 1660, probably in Spain.

The Clanaboy (or Clandeboye) branch of the O'Neills descended from the ancient kings through Neill Mor O'Neill, lord of Clanaboy in the time of Henry VIII, ancestor (as mentioned above) of the Portuguese O'Neills. Neill Mor's great-great-grandson, Henry O'Neill, was created baronet of Killeleagh in 1666. His son, Sir Neill O'Neill, fought for James II in Ireland, and died of wounds received at the battle of the Boyne. Through an elder line from Neill Mor was descended Brian Mac Phelim O'Neill, who was treacherously seized in 1573 by the earl of Essex, whom he was entertaining, and executed together with his wife and brother, about 200 of his clan being at the same time massacred by the orders of Essex. (*See* Essex, Walter Devereux, 1st Earl of.) Brian Mac Phelim's son, Shane Mac Brian O'Neill, was the last lord of Clanaboy, and from him the family castle of Edenduffcarrick, on the shore of Lough Neagh in Co. Antrim, was named Shane's castle. He joined the rebellion of his kinsman Hugh, earl of Tyrone, but submitted in 1586.

In the 18th century the commanding importance of the O'Neills in Irish history had come to an end. But John O'Neill (1740–98) took an active part in debate in the Irish parliament, being a strong supporter of Catholic emancipation. He was one of the delegates in 1789 from the Irish parliament to George, prince of Wales, requesting him to assume the regency. In 1793 he was raised to the peerage of Ireland as Baron O'Neill of Shane's Castle, and in 1795 was created a viscount. In defending the town of Antrim against the rebels in 1798 O'Neill received wounds from which he died on June 18, being succeeded as Viscount O'Neill by his son Charles Henry St. John (1779–1841), who in 1800 was created Earl O'Neill. Dying unmarried, when the earldom therefore became extinct, Charles was succeeded as Viscount O'Neill by his brother John Bruce Richard (1780–1855), a general in the British army; on whose death without issue in 1855 the male line in the United Kingdom became extinct. The estates then devolved on William Chichester, great-grandson of Arthur Chichester and his wife Mary, only child and heiress of Henry (d. 1721), eldest son of John O'Neill of Shane's Castle.

William Chichester (1813–83), 1st Baron O'Neill, a clergyman, on succeeding to the estates as heir general, assumed by royal licence the surname and arms of O'Neill; and in 1868 was created Baron O'Neill of Shane's Castle. On his death in 1883 he was succeeded by his son Edward, 2nd Baron O'Neill, who was member of parliament for Co. Antrim, 1863–80, and who married in 1873 Louisa, daughter of the 11th earl of Dundonald.

O'Clery, *Life of Hugh Roe O'Donnell* (Dublin, 1893). For the O'Neills of the 18th century, and especially the 1st viscount O'Neill, see *The Charlemont Papers;* and F. Hardy, *Memoirs of J. Caulfield, Earl of Charlemont,* 2 vol. (London, 1812). *The O'Neills of Ulster: Their History and Genealogy,* by Thomas Mathews, 3 vol. (Dublin, 1907), an ill-arranged and uncritical work, has little historical value, but contains a mass of traditional and legendary lore, and a number of translations of ancient poems, and genealogical tables of doubtful authority.

O'NEILL, EUGENE GLADSTONE (1888–1953), U.S. dramatist, was born in New York city on Oct. 16, 1888. He was, by common consent, America's greatest playwright, and an artist

of international renown. His career divided U.S. theatrical history in two. Before O'Neill, U.S. stages were awash with genteel, sentimentally spurious plays; he pioneered the drama of serious realism and uncompromising honesty.

When Eugene O'Neill took his place on the U.S. literary scene in the 1920s, it was to join a band of iconoclasts. H. L. Mencken was tilting with the "booboisie." Sinclair Lewis was baiting Babbitt. Sherwood Anderson was gingerly lifting the lid off sex. O'Neill ranged over the same themes but he sprayed them with a melancholy that clung like poison gas. Cries a leading character in *The Great God Brown:* "Why am I afraid to dance, I who love music and rhythm and grace and laughter? Why am I afraid to live, I who love life and the beauty of the flesh and the living colors of earth and sky and sea? Why am I afraid of love, I who love love? . . . Why was I born without a skin, O God . . . Or rather Old Greybeard, why the devil was I ever born at all?" (*The Plays of Eugene O'Neill,* 3 vol., New York, Random House, 1946.) O'Neill took this language of failure and flavoured it with the accent of tragedy. It was a convincing performance, in part, because failure is often regarded as tragic in America, and in part, because O'Neill had a rare mastery of his craft.

He came by a mastery of his craft early. His father James O'Neill was a matinee idol of the 1880s, playing for 16 years the count in *The Count of Monte Cristo*. Barnstorming with his father, young O'Neill soaked up theatrical know-how. In the fall of 1906 he entered Princeton university, Princeton, N.J., and flunked out the following spring. In the next few years he married and divorced, prospected for gold, went to sea and sailed the Atlantic from Southampton to South Africa. For O'Neill, the sea was a mystic experience, and some of the best of his 47 plays (e.g., *The Moon of the Caribbees, The Long Voyage Home*) are salty with the tang of the sea and the tongue of lonely, hard-bitten sailormen.

It was not until a mild case of tuberculosis bedded him in a sanitarium in 1913 that Eugene O'Neill thought of becoming a playwright. When the Provincetown (Mass.) Players produced his one-actor *Bound East for Cardiff* in 1916, modern American drama unofficially began. By 1920, O'Neill fashioned a Broadway success and won a Pulitzer prize with his first full-length play, *Beyond the Horizon,* a bitter domestic tragedy. O'Neill was already felt to be a man of morose views who could be counted on to find the worm in the apple of life. Actually his plays were cardiograms of the outraged heart, poignantly charting the cancelled dream, the twisted love, the thwarted hope.

O'Neill won two more Pulitzer prizes with *Anna Christie* (1922) and *Strange Interlude* (1928), and in 1936 became the second American (after Sinclair Lewis) to win the Nobel prize for literature. A restless technician, he thrilled theatregoers with tom-toms (*Emperor Jones*), masks (*The Great God Brown*), old-fashioned asides (*Strange Interlude*) and choral chants (*Lazarus Laughed*). A troubled thinker, he tried to pour modern experience into tragic moulds.

It has been said that tragedy is the story of man's fate. Greek tragedy is the tragedy of destiny. Man's fate is in his stars. Shakespearean tragedy is the tragedy of character. Man's fate is in his will. Through suffering and death, Greek and Shakespearean tragic heroes appeased the gods and found redemption. O'Neill had to cope with an audience that was almost as suspicious of God, will and destiny as of a flat earth. Bowing to his time, O'Neill wrote the tragedy of personal psychology. Man's fate is in his genes and hormones. But if man is his own fate, there can be no release, only an endless cycle of sin and guilt. Says Lavinia Mannon at the end of *Mourning Becomes Electra:* "There's no one left to punish me . . . I've got to punish myself!" (*The Plays of Eugene O'Neill,* 3 vol., New York, Random House, 1946.) O'Neill blended the determinism of John Calvin and Sigmund Freud to produce the only kind of tragic hero the 20th century could understand—the victim of circumstance.

The "sickness of today," O'Neill once said, was that the "old God was dead" and a new one was not in sight. To "belong" to the machine age, as O'Neill saw it, man had to be subhuman, an automaton. The instinct to love had been debased by possessiveness. The instinct to believe had atrophied. The best O'Neill could offer was chilly, stoic resignation. As the old barge captain puts it in *Anna Christie:* "You can't see where you vas going, no. Only dat ole devil, sea—she knows." (*The Plays of Eugene O'Neill,* 3 vol., New York, Random House, 1946.)

O'Neill sometimes handled these themes crudely. He wrote a kind of waterlogged English that never floated memorably across the mind. What he intended for encounters with the inexpressible were simply collisions with the badly expressed. When the juice of life ran low in his characters, he pumped them full of grease paint. His mind was an open manhole; ideas (J. A. Strindberg's, Freud's, C. G. Jung's) tumbled in but were never really absorbed. Yet there is something granitic in O'Neill that refuses to be chipped away—the sweep of his passion and compassion, the hypnotic moods he projects over the footlights and, above all, his probity. He never cheated with his evidence, and his evidence came from the heart. He never consciously wrote a shoddy line.

The coming of World War II sapped O'Neill's will to write; then a muscular disorder made it physically impossible. When he died he left at least three plays in manuscript, including the reportedly autobiographical *Long Day's Journey into Night,* which by the terms of his will could not be produced until 1978.

On the world's stages, only G. B. Shaw and Sean O'Casey clearly outrank him among 20th-century dramatists. Yet O'Neill never achieves the Aristotelian catharsis of pity and terror, or climbs to tragedy's classic realm where man's suffering and death stand bare, awesome and ennobling; his heroes wander instead, like eternally lost children through a haunted wood of pathos, futility, self-pity and frustration. But in his dedication to the best in his art form, Eugene O'Neill was a cultural hero, and as such, he left the U.S. theatre the memory of something finer than his best plays.

ONEONTA, the only city of Otsego county, N.Y., U.S., on state highways 7, 23 and 28 and the Susquehanna river, 76 mi. S.W. of Albany. It is served by the Delaware and Hudson and the New York Central railways. Pop. (1950) 13,564; (1940) 11,731. Oneonta is beautifully situated among the western foothills of the Catskills, at an altitude of 1,150 ft., in a fertile farming and dairying region. It is the seat of a state teachers' college, a state armoury and Hartwick college (United Lutheran; founded 1928). The manufacturing industries include extensive railroad shops and dress and glove factories.

Oneonta was founded about 1780 and until 1830 was known as Milfordville. It was incorporated as a village in 1848 and as a city in 1908. The name is derived from the Indian name for the creek flowing through the city.

ONESICRITUS or Onesicrates, of Aegina or Astypaleia (probably simply the "old city" of Aegina), one of the writers on Alexander the Great. At an advanced age he became a pupil of Diogenes the Cynic, and gained such repute as a student of philosophy that he was selected by Alexander to hold a conference with the Indian Gymnosophists.

When the fleet was constructed on the Hydaspes, Onesicritus was appointed chief pilot (in his vanity he calls himself commander), and in this capacity accompanied Nearchus on the voyage from the mouth of the Indus to the Persian gulf. He wrote a diffuse biography of Alexander, which in addition to historical details contained descriptions of the countries visited, especially India. After the king's death, Onesicritus appears to have completed his work at the court of Lysimachus, king of Thrace. Its historical value was considered small, it being avowedly a panegyric, and contemporaries (including even Alexander himself) regarded it as untrustworthy.

Strabo especially takes Onesicritus to task for his exaggeration and love of the marvellous. His *Paraplus* (or description of the coasts of India) probably formed part of the work, and incorpo-

rated by Juba II of Mauretania with the accounts of coasting voyages by Nearchus and other geographers, and circulated by him under the name of Onesicritus, was largely used by Pliny.

ONION, *Allium cepa* (family Liliaceae), a hardy bulbous biennial which has been cultivated from time immemorial. It is one of the earliest of cultivated plants; it is represented on Egyptian monuments, and one variety cultivated in Egypt was accorded divine honours. It is commonly cultivated throughout the temperate zones. A. de Candolle regards it as a native of western Asia. The edible part of the onion is the thickened bases of the leaves that arise from an extremely shortened or telescoped stem, the small hard structure at the base of the bulb, called the stem plate. The upper portion of the leaves is cylindrical and hollow. The seed stalk formed in the second season may be 2 to 5 ft. tall, topped by a globose umbel of small whitish flowers. In some types of onions this umbel is replaced by a cluster of bulblets, or bulblets and flowers. The seeds are small, black and shaped roughly like halves of a sphere. Most varieties of onion are sensitive to the length of day and night. Varieties adapted to summer culture in northern latitudes when the days are long will not form normal bulbs and ripen when grown during the short winter days of lower latitudes although soil and temperature may be favourable. Conversely, certain varieties that make large bulbs during the short winter days of low latitudes ripen and stop growth when very small if grown during long days in higher latitudes. There are three main classes of onions: (1) those forming well-developed bulbs the first season and seeds the second season; (2) forms in which bulbs form at the top of the stalk; (3) the nonbulbing multiplier onion that is propagated by division of the cluster of vegetatively produced plants. The mild Spanish type of onion must be used soon after harvest while the hot, firm, northern varieties can be stored all winter.

Most varieties, particularly those grown extensively in Great Britain and the northern parts of Europe and the United States, require a cool or mild mean temperature. The Spanish and Egyptian types will tolerate hot days of spring or early summer but are not adapted to midsummer heat of the lower latitudes. Seed must thus be sown as far ahead of summer heat as possible, and still escape sharp freezing weather: late February to mid-March in England, or late March and early April in the northern United States. In the southwestern United States and in England seed of adapted varieties is sown in the fall. A large portion of the crop in the United States is grown from seedlings transplanted from plant beds to the field 3 in. apart, and from small dry bulbs or sets grown from seed the previous year. Small bulbs or sets are grown by planting seed very thickly (50 to 100 lb. per acre) in a wide band, on soil of moderate fertility, thus crowding and stunting the plants. Onions require rich soil, especially well prepared. Onions grown from seed sown in the field require careful thinning to 2 to 4 in. apart in the rows, depending on variety and conditions of culture. Rows are usually 1 to 1½ ft. apart. The average annual production of onions in the United States, for market, was (1942–51) about 14,316,000 sacks of 100 lb. each. Production in 1952 was 39,414,000 sacks. (V. R. B.; X.)

ONION MAGGOT, the common name of *Hylemya antiqua* of the family Muscidae of the order Diptera (*q.v.*), which attacks the roots of onions and related plants. The eggs are laid on the soil close to the plants; the young larvae feed on the roots or attack the bulbs and bases of the leaves. Many other insects are attracted to and feed upon the damaged onions. Species commonly found associated with *H. antiqua* are the lesser bulb fly, *Citabaena tuberculatus,* and species of *Fannia.* Modern treatment consists of watering the plants with a solution of corrosive sublimate. (*See* ENTOMOLOGY: *Economic Entomology.*)

(C. H. CN.)

ONOMACRITUS (*c.* 530–480 B.C.), seer, priest and poet of Attica. He had great influence on the development of the Orphic religion and mysteries, and was said to have composed a poem on initiatory rites. The works of Musaeus, the legendary founder of Orphism in Attica, are said to have been reduced to order (if not actually written) by him (Clem. Alex. *Stromata,* i, p. 143 [397]; Pausanias i, 22, 7). He was in high favour at the court of the Peisistratidae until he was banished by Hipparchus for making additions of his own in an oracle of Musaeus. When the Peisistratidae were themselves expelled and were living in Persia, he furnished them with oracles encouraging Xerxes to invade Greece and restore the tyrants in Athens (Herod. vii, 6).

See F. W. Ritschl, "Onomakritos von Athen," in his *Opuscula,* vol. i, and p. 35 of the same volume (1866); Smith, *Dict. of Gk. and Roman Biography,* s.v. (bibl.).

ONOMATOPOEIA, a term used in philology to denote the formation of words by imitation of natural sounds, *e.g.,* "hiss," "click" and "hush."

Some philologists held that the term "echoism" for this process was preferable, since it suggested the imitative repetition of the sounds heard.

At one time there was an exaggerated tendency to find in echoism a principal source in the origin and growth of language, ridiculed as the "bow-wow" theory of language; it was recognized, however, that it played only a limited part.

Onomatopoeia means literally the making or formation of words. It was derived from the Greek ὀνοματοποιία, from ὄνομα, name, word, ποιεῖν, to make.

ONONDAGA, a tribe of North American Indians of Iroquoian stock, forming one of the Six Nations. The tribal headquarters was about the lake and creek of the same name in New York state. Its territory extended northward to Lake Ontario and southward to the Susquehanna river. It was the official guardian of the council fire of the Iroquois. Its chief town, near the site of the present Onondaga, consisted of about 140 houses in the middle of the 17th century, when the tribe was estimated as numbering between 1,500 and 1,700. During the 18th century the tribe divided, part loyally supporting the Iroquois league, while part, having come under the influence of French missionaries, migrated to the Catholic Iroquois settlements in Canada. Of those who supported the league, the majority, after the War of Independence, settled on a reservation on Grand river, Ont., where their descendants remained.

In 1926 there were 568 upon the Onondaga reservation in New York state. (*See* also NORTH AMERICA: *Ethnology.*)

See F. W. Hodge (ed.), *Handbook of American Indians North of Mexico,* pt. ii (Washington, D.C., 1910).

ONTARIO, a province of Canada, bounded by Quebec to the east, by the states of New York, Ohio, Michigan and Minnesota to the south, by Manitoba to the west and by part of Hudson bay with James bay to the north. In most cases the actual boundary consists of rivers and lakes: the Ottawa to the northeast; the St. Lawrence and its chain of lakes and rivers to the south as far as Pigeon river, which separates Ontario from Minnesota. From this point it follows small rivers and lakes to the Lake of the Woods between Ontario, Minnesota and Manitoba. From Lake of the Woods northward the western boundary follows approximately the meridian of 95° almost to the 53rd parallel, and then swings northeastward to Hudson bay. From Lake Timiskaming northward the eastern boundary is the meridian of 79° 30′.

Physical Geography.—Ontario extends 1,000 mi. from east to west and 1,050 mi. from north to south, between latitudes 57° and 42°, including the most southerly point in Canada. Its area is 412,582 sq.mi. (49,300 water), and it is the most populous of the provinces, but the bulk of its inhabitants live in one-tenth of its area, between the Great Lakes, the Ottawa and the St. Lawrence, a country of relatively fertile soils.

The control of settlement by geology is readily observed in southern Ontario. Reference to the mantle map (fig. 1) shows that the good farming country is all south of the Pre-Cambrian shield, the edge of which extends from the Muskoka lakes to the St. Lawrence near Kingston. There is also a corner of southern Ontario (in the southeast) where the surface rocks are younger than the shield. Separating these two is the notable feature called the Frontenac axis, where an upfold has brought the granites of the shield to the surface. It is this bar of hard granite which determines the presence of the Thousand Islands in the St. Lawrence, and which causes the many rapids (and canals) between Kingston and Montreal, Que.

To the southwest of the shield the map shows that southern Ontario consists of a series of Palaeozoic beds dipping gently to the southwest. Over the granites come the Ordovician rocks, between Toronto and Kingston. These are often shales which produce good materials for bricks. Then, quite suddenly, rises the pronounced Cuesta of Silurian rocks, north and south of Hamilton. This consists of a hard dolomitic limestone which extends as a fairly continuous scarp from Albany, N.Y., around Lake Michigan to Chicago. In the Silurian rocks are considerable beds of gypsum, which are worked to the south of Guelph. Still farther west is an overlying layer of Devonian rocks which form the surface deposits between Kitchener and Detroit, Mich. Bores through these deposits have tapped gas, oil and brine springs, all of considerable commercial value. Unfortunately, Carboniferous rocks do not occur in Ontario, but are widespread in Michigan, where valuable coal seams are worked in these youngest rocks of the region. (Fig. 1.)

The higher areas of southern Ontario consist of rolling hills of boulder clay or moraines; the lower levels are plains sloping toward the Great Lakes and containing the silt deposited in ancient lakes at the end of the glacial period. The old shore cliffs and gravel bars of those glacial lakes frequently provide sites for roads, towns and cities. The Niagara escarpment is the cause of waterfalls on all the streams which plunge over it, Niagara falls being, of course, the most important.

While all the larger cities and most of the manufacturing and farming districts are in southern Ontario, there is developing a "new Ontario," stretching for hundreds of miles to the north and northwest of the region just described and covering a much larger area, chiefly made up, except for an extensive clay belt, of ancient rocks forming the Pre-Cambrian shield. The rocky character of that area long repelled settlement until its abundant minerals, water powers and northern forests invited exploitation. Later, industries dependent upon these natural resources drew population.

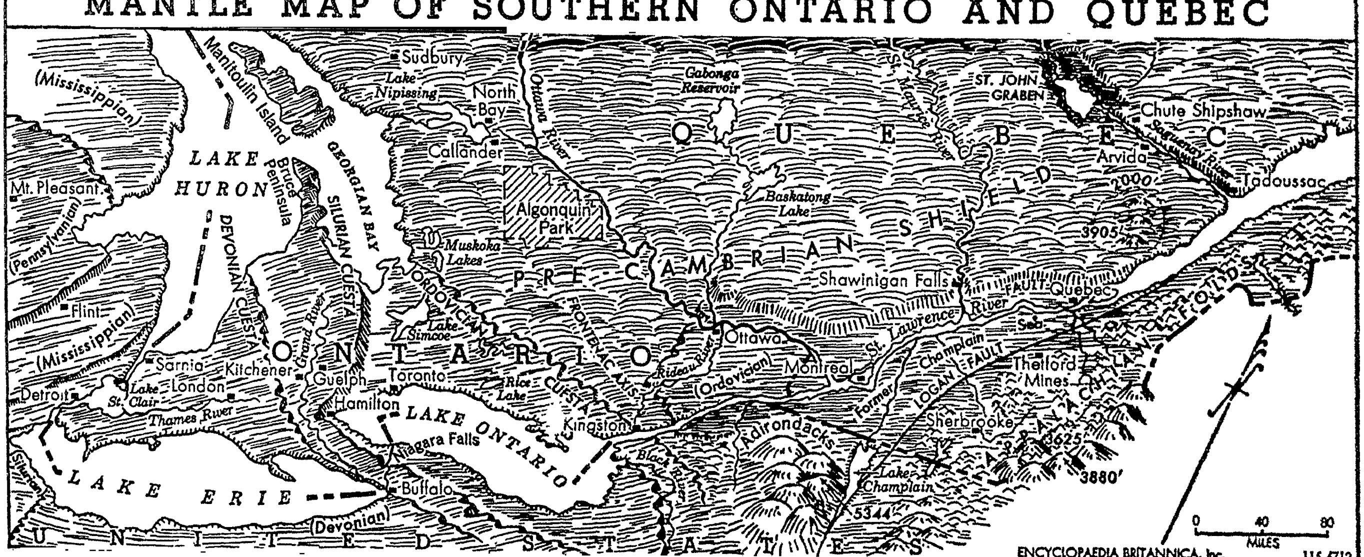
Lakes and Rivers.—Numerous lakes and rivers are scattered throughout Ontario, the most important chain being that of the St. Lawrence and the Great Lakes with their tributaries, which drain the more populous southern districts. Lake Nipigon, a beautiful body of water 852 ft. above the sea, 70 mi. long and 50 mi. wide, may be regarded as the headwaters of the St. Lawrence, since Nipigon river is the largest tributary of Lake Superior. All the rivers entering Lake Superior have high falls which provide power for the industries of the region. At the southeastern end of Lake Superior the St. Mary's river carries its waters to Lake Huron with a fall from 602 to 581 ft., most of which takes place at Sault Ste. Marie where locks permit vessels of 10,000 tons to pass from one lake to the other and where water power is generated. The northeast shores of Lake Huron and its large expansion, Georgian bay, are fringed with numerous islands, mostly small, but Manitoulin Island, 80 mi. long and 30 mi. broad, is a notable exception. This island and the Bruce (Saugeen) peninsula shut away the greater part of Georgian bay from the main lake. The eastern shore of Georgian bay is bordered with "Thirty Thousand Islands," and is so named.

Lakes Superior and Huron both reach depths hundreds of feet below sea level, but Lake St. Clair, toward which Lake Huron drains southward through the St. Clair river, is shallow and marshy. Detroit river connects Lake St. Clair with Lake Erie at an elevation of 572 ft., and this comparatively shallow lake, running for 241 mi. east and west, empties northward by Niagara river into Lake Ontario, which is only 245 ft. above the sea. Niagara falls, with rapids above and below, hurry the waters of the upper lakes over the Niagara escarpment, and provide hydroelectric power for the industries of southern Ontario. The Welland canal, between Port Colborne on Lake Erie and Port Weller on Lake Ontario, has a limiting depth between locks of 25 ft. and of 30 ft. in the locks. From Lake Ontario the St. Lawrence passes through the meshes of the Thousand Islands and follows several rapids, separated by stretches of quiet water, to Montreal at the head of ocean navigation. Some steamers can run the rapids going down, but must ascend through the canals. All other rivers in southern Ontario are tributaries of the lakes or of the St. Lawrence. The Ottawa, navigable by the use of locks to the city of Ottawa, is the largest. The 240-mi. Trent waterway (rivers and lakes joined by locks and canals) connects Trenton on the Bay of Quinte (Lake Ontario) and Port Severn on Georgian bay; and the 124-mi. Rideau waterway connects the cities of Ottawa and Kingston. Numerous lakes in northern Ontario constitute a picturesque region for summer resorts, especially Lake Timagami, the Muskoka lakes and Lake of the Woods, the last mentioned forming part of the Hudson bay system of waters flowing through Manitoba.

In northern Ontario the Albany, Moose, Winisk, Severn and their many tributaries flow into Hudson bay, but none of those rivers is navigable except for canoes.

Climate.—The climate of Ontario varies greatly, as might be expected from its wide range of latitude and the relations of the Great Lakes to the southern peninsula of the province. The northern parts, as far south as the north shore of Lake Superior, have long and cold but bright winters, with temperatures reaching sometimes −50° F.; while the summers are delightful, with much sunshine and some hot days but pleasantly cool nights. Between Georgian bay and Ottawa the winters are less cold, but usually

MANTLE MAP OF SOUTHERN ONTARIO AND QUEBEC



ADAPTED FROM GRIFFITH TAYLOR'S "CANADA" (METHUEN & CO., LTD.)

FIG. 1.—A MANTLE MAP IS A DIAGRAMMATIC REPRESENTATION GENERALIZED TO SHOW THE STRUCTURE AND GEOLOGY OF THE REGION

have a plentiful snowfall; while the summers are warm. At Cochrane in the northern clay belt the range of temperature is from 0° F. in January to 63° F. in July. At Toronto the similar range is from 22° F. to 68° F. The southwest peninsula of Ontario has a climate greatly modified by the lakes which almost enclose it. Since the lakes never freeze, the prevalent cold northwest winds of North America are warmed in their passage over them, and often much of the winter precipitation is in rain, resulting in weather more uncertain than that in the north. The rainfall increases fairly regularly from 20 in. in the far northwest to 38 in. in the southeast. The summers are often sultry, although the presence of the lakes prevents the intense heat experienced in the states to the south and west. Because of its mild winters, the southwest peninsula is a famous fruit country, and also grows such field crops as Indian corn (maize) and tobacco. Small fruits and the common garden vegetables are widely cultivated for the city markets and the canning industry.

History.—Samuel de Champlain was the first European to record anything about the present Ontario. In 1613 he went up the Ottawa in a vain search for the northern ocean; and in 1615 he pushed westward and reached the eastern shores of Lake Huron, the first to tell of the Great Lakes with their vast stretches of fresh water.

Missions to the natives were a chief interest of the French pioneers in Canada and within Ontario is found their earliest important effort. Huronia, on the borders of Lake Simcoe and the Georgian bay, the scene of a promising Jesuit mission, was devastated by the Iroquois in 1649 with the martyrdom of Fathers Brébeuf, Lalemant and others, making one of the most tragic stories in Jesuit annals. Meanwhile, the fur trade expanded, and before the British conquest the French had trading posts at strategic points; Fort Frontenac, where modern Kingston is—a defiance of the Iroquois—at the northeast end of Lake Ontario; Toronto, on its north shore, near the west end; Niagara; Detroit; Michilimackinac at the entrance to Lake Michigan; Sault Ste. Marie; and on the greatest and farthest lake, Superior, a fort near where the modern city of Fort Williams stands.

The French, however, did little settlement, and apart from such posts, Ontario was still virgin wilderness in 1763 when it became British. In 1774, by the Quebec act, it became a part of the province of Quebec ruled from Quebec city by an appointed Roman Catholic-Protestant council. The American Revolution began the next year and for the first time came serious settlement by exiled loyalists from the United States, bitterly hostile to that country. The Quebec act entrenched the civil law of France; but the loyalists wished English law and a representative assembly, and in 1792 two Canadas were created: Lower Canada, east of the Ottawa river; Upper Canada, west; each with its own legislature. At once Upper Canada adopted English law. The first governor, John Graves Simcoe, considered the seat of government at Niagara too near the American frontier; and it was quickly changed to York, the modern Toronto.

Simcoe, a soldier who was later appointed commander in chief in India, was alert to the problems of defense. When war with the United States broke out in 1812, the Americans captured and burned York, for which the British retaliated in 1814 by burning the capitol at Washington, D.C. Only after peace in 1814 and the fall of Napoleon in 1815 was there adequate opening for development. English, Scots and Irish arrived in considerable numbers, until, by 1837, there were 350,000 people in Upper Canada. Political differences became acute; one extreme wing, composed chiefly of the loyalist elements, was reactionary; the other, led in the end by a Scot, William Lyon Mackenzie, was radical. In Lower Canada there was a similar issue with Louis Joseph Papineau as the radical leader. Holding the middle ground, on clear-cut principles of constitutional right, was Robert Baldwin. He claimed that in Upper Canada as in England the head of the state must govern through advisers who had the confidence of the people. After abortive rebellion in both provinces in 1837–38 a striking political evolution took place. Upper and Lower Canada were united in 1842 under a parliament in which they had equal representation. Sectionalism as between French and English endured and the solution was found in 1867 in a federal system. (*See* CANADA: *History*.)

The long Liberal ministry of Sir Oliver Mowat (1871–96) was followed by a decline of the party's prestige, and in 1905 the Conservatives, led by Sir James Whitney, came into power. In 1916, during World War I, Whitney's successor, Sir William Hearst, passed a drastic prohibition law relating to the sale of intoxicating liquors. An election in 1919 gave the new Farmers' party a larger number of members than had either the Conservatives or the Liberals and they took office under C. A. Drury. They showed a lack of experience, and in 1923, while the Liberal party made a poor showing, the Conservatives, under G. Howard Ferguson, came into power with a large majority. There was discontent with the rigour of the Prohibition law, and in 1926 Ferguson carried his second election by securing a large majority for the system of state control of the hard liquor traffic under individual licences and strict supervision and rigid state inspection of beverage rooms (also called beer parlors), where beer and ale could be bought. In 1947 the Ontario Liquor Control act was expanded to permit operation of licensed cocktail bars and lounges.

The Conservatives were sustained in power in the general election of 1929, but Ferguson, who in 1930 accepted the office of Canadian high commissioner in London, was succeeded by G. S. Henry in the provincial premiership. The party was defeated in 1934 and the Liberals assumed office under Mitchell Hepburn, who was succeeded in 1942, in a cabinet reconstruction, by his colleague Gordon Conant, but remained in office as provincial treasurer. The leadership of the Conservatives in opposition passed to Col. George Drew. During Hepburn's regime Ontario politics centred largely on power policy, on the cancellation by the Ontario government of the contracts with extraprovincial power companies, by virtue of jurisdiction over property and civil rights (British North America act [§ 92]). With this went a general alienation of the policy of Hepburn's Liberal government from that of the Liberal government at Ottawa. In 1943 Drew led the Conservatives to power and became premier, but in 1948, while the Conservatives again won the election, Drew was personally defeated and entered federal politics. The Ontario Conservatives were led in turn by T. L. Kennedy and Leslie Frost, who in turn became premier.

Population.—The population growth of the province after 1911 is reflected in the decennial censuses:

	1911[1]	1921	1931	1941	1951
Population of province . .	2,527,292	2,933,662	3,431,683	3,787,655	4,597,542
Percentage of the total Canadian population . .	35.07	33.38	33.07	32.89	32.82

The percentage increase of the population in 70 years (1871–1941) was 131.77. In 1951 the density of population was 12.55 per square mile of land area compared with the 1941 average of 5.74 for the nine provinces. An increasing percentage of the people lived in cities, towns or incorporated villages, as is illustrated in two such census years as 1911 and 1941:

	1911	1941
Percentage of population rural	47.43	38.3
Percentage of population urban	52.57	61.7

The smallest urban unit, the village, when asking for incorporation must by provincial law have a population of at least 750 in an area not exceeding 500 ac. The villages are numerous, and in 1951 Ontario had 70 cities and towns with more than 5,000 inhabitants. In 1951 Toronto, the largest city and capital of the province, had a population of 670,945, and Greater Toronto, which included the satellite communities in close relationship to the city, had 1,108,532. Four other important cities, each having more than 100,000 people, were Hamilton, Ottawa, London and Windsor. Ontario ranked third among the nine provinces in the proportion of the British in its population. In 1941, 72.6% of the people were of British origin, 9.9% French, 16.5% European other than British and French and the rest of Asiatic and indigenous origin. The French settlements are mainly near the St. Lawrence and in the

newer areas of northeastern Ontario. The strongest sectarian group numerically in 1941 was the United Church, which as in other provinces resulted from union of the Methodists, Congregationalists and Presbyterians. Its strength and influence gave a puritan tone to social life and legislation. Next in strength of membership was the Roman Catholic Church followed closely by the Anglican.

Government.—The structure of government in Ontario differs little from that in other Canadian provinces. Nominally executive power is vested in a lieutenant governor appointed for five years by the federal administration, but actually it dwells in an executive council (or cabinet) the members of which sit in and are responsible to an elected legislature in unison with the traditional British principles of cabinet government. The legislature consists of one house, of 90 members, elected on a wide franchise including women; its maximum life is five years unless extended by a special act. The revenue of the provincial government has been derived from a variety of direct taxes, licences, federal subsidies, royalties from use of resources, and returns on the sale and control of liquor. An extensive system of municipal administration came into existence in the middle of the 19th century, and by 1949 slightly more than one-tenth of the area of Ontario was municipally organized and embraced 43 counties, 29 cities, 147 towns, 157 villages, 571 townships and 13 improvement districts, all possessing in some form elected councils and officials with some taxing power on property. The municipal regime of Ontario influenced notably the municipal development in other provinces, especially the provinces of the west.

Education.—Ontario has been distinguished for its ready support of education. In the early years the legislature made considerable grants of land for this purpose, and by mid-20th century no other service of government absorbed so large a proportion of the provincial expenditure. A minister in the executive council is responsible to the legislature for policy, but his permanent deputy may exercise a more important influence. School inspectors, appointed by the provincial department, endeavour to secure uniform standards throughout the province, while in every school section elected trustees levy taxes, appoint the teachers and in general provide for the needs of the local school. Attendance is compulsory between the ages of 8 and 16 although in rural areas permission is readily obtained for children to work on farms from the age of 14, and under special conditions the law may be relaxed also in the cities. The public schools are free and undenominational, but not secular, since prayer and Bible reading may hold a place in the daily program. From 1863 the Roman Catholics exercised the right to separate schools, set up in any district upon request of not less than five heads of families. Taxes levied upon the supporters of these institutions are devoted wholly to their maintenance. Protestants and Negroes may also claim, but rarely do, the right to separate schools.

Secondary education, with increased emphasis on social studies, is provided in high schools and collegiate institutes, which may require fees or give free education at the option of the local trustees. There are also many incorporated private schools, exempt from municipal taxation. They are grouped principally in Toronto and its neighbourhood, the most distinguished being Upper Canada college, founded in 1829. Higher education is provided by the provincial university in Toronto, Queen's university in Kingston, the University of Western Ontario in London, McMaster university (Baptist) in Hamilton and the University of Ottawa (Roman Catholic) in the federal capital. In 1942 Carleton college (nondenominational) was founded in Ottawa. The provincial institution, known as the University of Toronto, had in 1951–52 a student body of more than 11,000 in all faculties. It is a federation of colleges, with a distinguished place among the universities of North America. All the universities are coeducational, and women generally form about two-fifths of the whole student body. In addition to the universities, model and normal schools exist to train teachers, while scientific agriculture is promoted by the Ontario Agricultural college at Guelph, founded and endowed by the government.

Agriculture.—Ontario is Canada's richest agricultural province. The value of its farm capital (including land, buildings, implements and stock) at mid-20th century exceeded one-fourth of the total value of farm capital in Canada; the same remark may be made of the gross values of its agricultural production; and the average value per acre of its occupied farm land ranked next to that of British Columbia. The wide variety of production is notable. Field crops take the lead in gross value, followed by dairying, production of farm animals, poultry products, fruits and vegetables (much production for canning), sugar beets and tobacco. Wheat growing has long ceased to hold the premier place held by it in the prairie provinces, and farmers, not depending upon the foreign wheat market, are saved from the rapid changes of income suffered by their compatriots farther west. The average Ontario farmer has won relative security through diversification made possible by the presence of urban markets and a suitable climate and fertility. A mixed and pioneer farming is found in the clay belt of the north, the products being sold in the mining centres.

Environment and Settlement.—A glance at the generalized population map appearing as a part of fig. 2 shows that with few exceptions the moderate and dense populations are to be found south of the Pre-Cambrian shield. The empty loop, which is due to the southern extension of the shield known as the Frontenac axis, is well brought out in the map. However, the great importance of the tourist traffic in the lake region of Muskoka—on the shield to the north of Toronto—led to the development of a host of small farms, which raise some hay and cows, but depend largely on summer visitors. Well to the north are two areas of moderate settlement, which are entirely due to the presence of the unrivalled nickel resources of Sudbury, or to the gold of the region between Timmins and Cobalt. The considerable extension of sparse settlement (even in the northern shield) along the northern railway is due to the presence of the clay belt, the residue of a huge former glacial lake.

South of the shield the main distributions of the croplands are shown in separate maps in fig. 2. One map shows the number of acres cleared in each square mile (*i.e.*, in each 640 ac.). In the west of the peninsula almost the whole is cleared (500 of each 640 ac.). The edge of the shield agrees fairly well with the 300 line on the map; so that there, as in the population map, the "Frontenac axis" shows up well. Croplands are denser again in the small area of Palaeozoic rocks to the south of Ottawa. By far the main crops of southern Ontario consist of oats and hay, so that the distribution of cleared land indicates fairly closely the distribution of oats and hay. The other map in fig. 2 shows the distribution of minor crops. Vines shelter under the scarp of the Niagara peninsula, and tobacco grows on the sandy soils of the hottest part of Canada. There also silo maize (corn) grows thickest, while the milch cows are densest in the London region to the north. Orchards are found along the shore of Lake Ontario, and potatoes are grown close to the great city of Toronto since their transport is difficult. The great industrial belt, including the "quadrilateral" of the big cities of Toronto, Hamilton, Kitchener and London, is indicated in the population map of fig. 2.

Manufactures.—Ontario long led the other provinces individually in the gross and net value of manufactures; indeed, until 1940 the gross value of its manufactures equalled that of the remainder of Canada, and even the net value at mid-century still exceeded greatly that of agriculture within the province. This premier place of manufacturing in the economy is due finally to the geographic assets of Ontario, the fertile soils maintaining many farmers with a high level of living, the presence of rich forest and mineral resources, the relative proximity to the coal and iron ore of the United States, the cheap transport afforded by the St. Lawrence and the Great Lakes and the abundance of water power which made up for the absence of domestic coal and stimulated the rise of electrometallurgical industry. In manufactures, as in agriculture, the variety of production is notable; it includes nonferrous metal smelting and refining, automobiles, agricultural implements, meat-packing products, electrical apparatus, machinery, pulp and paper, flour and livestock feed, rubber goods, leather, butter, cheese, primary iron and steel, furniture, hosiery, knit

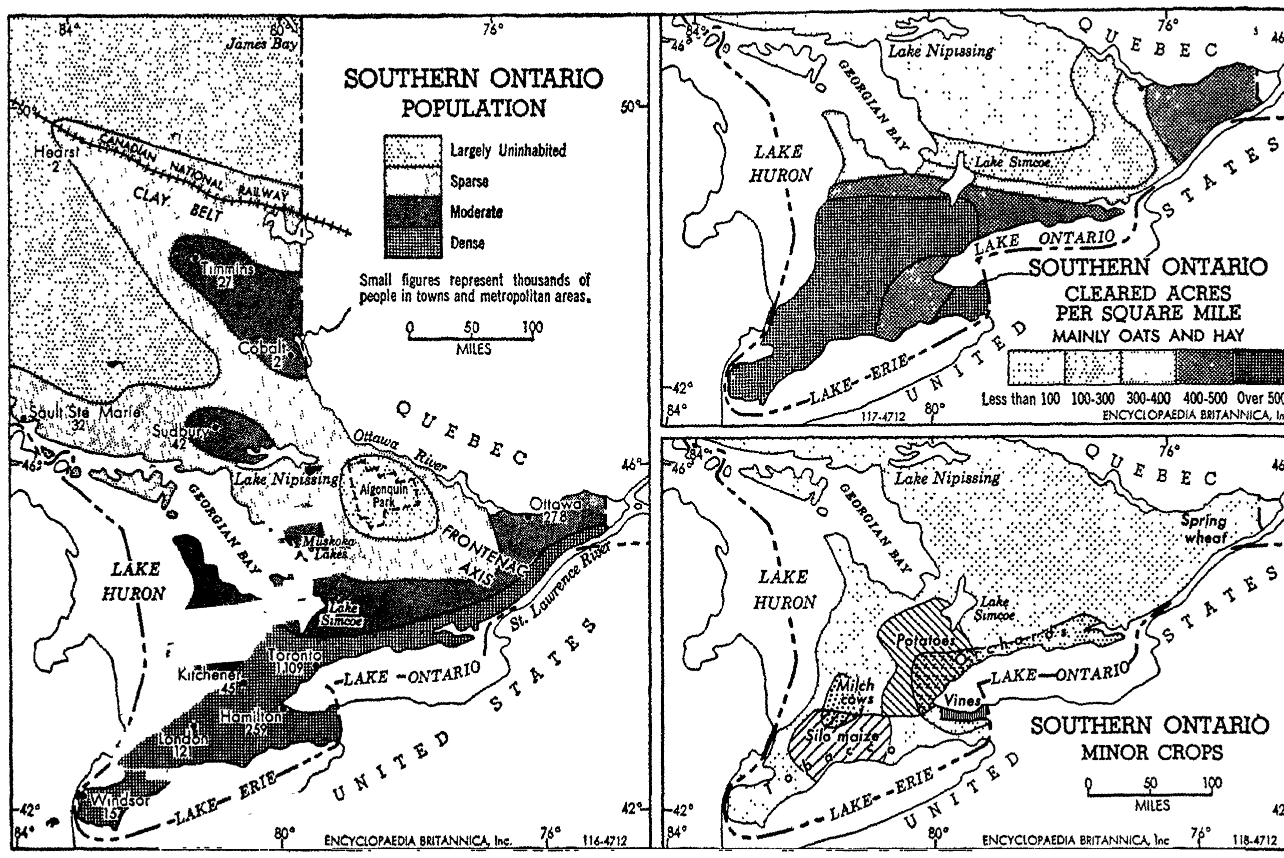


FIG. 2.—POPULATION: DENSEST SETTLEMENT IS IN THE EXTREME SOUTH ALONG LAKE ERIE, LAKE ONTARIO AND THE ST. LAWRENCE RIVER. CLEARED ACRES: THE MARKED EASTWARD LOOP OF THE 100–300 CLEARED ACRES PER SQUARE MILE AREA INDICATES THE POOR SOILS OF THE FRONTENAC AXIS. MINOR CROPS: NEARLY ALL THE MINOR CROPS ARE GROWN IN THE SOUTHWEST WHERE THE MODERATING EFFECT OF THE LAKES ON TEMPERATURE IS GREATEST

goods, gloves, canned fruit and vegetables, petroleum products, biscuits and miscellaneous foods, clothing, printing and bookbinding, railway rolling stock, breweries and tobacco processing. At mid-20th century Ontario manufactured three-fourths or more of the "Made-in-Canada" products from iron, nonferrous metals, leather, rubber, cordage, wool and abrasives; one-half or more of the products from chemicals, aluminum, wheat and coal; and about one-third of the products made from paper, glass and wood. Significant in the development of manufacturing was the extension of U.S. branch plants, which concentrated in Ontario more than in any other province.

Water Power.—Among Canadian provinces in 1949 Ontario ranked second only to Quebec in the horsepower developed and in potential power resources. In Dec. 1949 the figure of turbine installation was 2,896,540 h.p. and the available 24-hr. power at ordinary six-month flow was estimated at 7,621,000 h.p. Most of the power is developed in central electric stations, but much is produced by pulp and paper mills and other industries. Ontario was the pioneer province in the public ownership of hydro power. In 1906 it constituted the Hydro-Electric Power commission, which at first merely bought power generated at Niagara by private companies and transmitted it at cost to the municipalities, the initial capital being provided by the government. Later the commission purchased the private companies at Niagara and elsewhere, and thus achieved for public ownership the most vital force in the industry of the province. Public opinion and all the political parties consistently supported this policy of public ownership, although some details of the policy gave rise to sharp controversy. In 1949 the commission served 1,017 municipalities and 1,078,221 customers with a total of 2,150,231 kw. In Sept. 1950 demand on the commission reached a new all-time high of 40,933,035 kw.hr. Modern significant developments were the purchase and import of power from private Quebec companies (some power is transmitted 225 mi. from the Gatineau river to Toronto) to meet the expanded needs of manufactures in southern Ontario; the utilization of many power sites in the north, notably on the Abitibi, to aid mining and the pulp industry; the extension of rural electrification through subsidies from the government to about 270,000 customers by Jan. 1950; and the diversion of water from parts of the Kenogami and Ogoki rivers, which are tributaries of the Albany flowing to James bay, into the Lake Superior system, thus ultimately increasing the hydro power of the Niagara. During 1949–50 the commission undertook intensified hydroelectric construction on the Ottawa, Madawaska, Nipigon and Mississagi rivers, putting about 1,098,000 h.p. more into transmission lines by the end of 1951. In addition, steam plants at Toronto and Windsor, with a total capacity of 386,000 h.p., were brought into operation in 1951. On June 14, 1950, Canada ratified with the United States a treaty which allocated Canada enough extra water from the Niagara river for an additional 900,000 h.p. of hydroelectricity, construction for which began late in 1950.

Mining.—From 1907 to 1940 Ontario was the chief mineral-producing province of Canada, but by 1949 its annual contribution fell to 35% of the total mineral production. The minerals are varied, including gold, silver, cobalt, radium, copper, nickel, lead, zinc and practically all the commercial nonmetallic minerals except coal. The richest mining areas are in the extensive Pre-Cambrian region of northern Ontario, although petroleum, natural gas and salt have been developed in the southwestern peninsula of the province. For many years, because of the nickel-copper deposits at Sudbury, Ontario has been the principal producer of the world's supply of nickel, turning out in the 1938–48 period about 90% of the world total exclusive of the U.S.S.R. The International Nickel company at Sudbury became noted for finding varied industrial uses for its metal. But in the economic life of Ontario for many years the crucial mineral factor was gold, of which that province produces between 50% and 60% of the total Canadian output. There as elsewhere the special stimulus to mining came with the revaluation of gold in the depression of the 1930s, when old properties were enlarged and new mines were dis-

covered and speedily developed. In 1948 the federal government's emergency gold mining assistance law kept a number of marginal mines in operation despite higher working costs. The consequence of these influences on Ontario gold mining was reflected in production figures: 1925, 1,461,039 fine oz.; 1941, 3,194,308; 1948, 2,068,-978; 1950, 2,448,764. Most of the Ontario gold comes from auriferous quartz mines in the districts of Porcupine and Kirkland lake. In contrast with the gold of Quebec and Manitoba, only a negligible quantity is derived from mines producing ores of copper, nickel and zinc. Ontario also has much iron ore, generally of low grade, but the development of an extensive subaqueous mine of high grade ore at Steep Rock lake west of Port Arthur was stimulated by World War II.

Forest Industry.—More than 60% of the land area of Ontario, or about 241,000 sq.mi., is classified as forested. The area of merchantable timber is of course much smaller than this figure, being about 66,000 sq.mi. Among the provinces, Ontario ranks second only to Quebec in total stand of conifer and broad-leaved timber, estimated in 1949 at 58,000,000,000 cu.ft. out of a total for Canada of accessible timber of 191,000,000,000 cu.ft. Undue importance, however, need not be attached to the precise figures, since in detail they are subject to error and are constantly revised. It is sufficient to emphasize that Ontario has highly valuable forests which continued to influence profoundly its economic development, as they helped to shape its history, feeding with raw material many secondary manufactures. Its commercial woods are varied. White pine, durable and easily worked, has the largest market, while red pine, spruce, jack pine, birch, hemlock, balsam and maple are also significant. The pulp and paper industry, providing much employment and facilitating Canadian foreign exchange, is central in the forest economy of northern Ontario, where it exists as the dominant secondary industry not merely because of abundant spruce and balsam but also because of hydro power in the numerous rivers of the Pre-Cambrian shield. Secondary to pulp and paper but important is the sawn lumber industry, which found a wider market in manufactures when World War II checked the displacement of lumber materials by metals. Because of the shortage of light metals, for example, wood was reintroduced into the manufacture of aeroplanes. Progress was made in forest conservation, notably in fire control with the effective aid of lookout towers, aviation, the world's largest forestry radio network and more rigorous regulations. The Ontario forests had been recklessly exploited, and in the southern part of the province many counties at mid-20th century had less than 10% wood coverage, not always sufficient even to protect watersheds. In 1949 a target of 18%–25% forest cover was set for the depleted southern counties; a year later capacity of the provincial nurseries was increased to 60,000,000 seedlings annually for free distribution (20,000,000 shipped in 1949), and timber management was started over 165,000 sq.mi. of northern forest. Of the eight proclaimed provincial forests, the largest is Timagami, wherein settlement is prohibited, and no timber may be sold except by order in council. It is the aim to bring those forests on a sustaining yield basis. Two provincial forest parks are Algonquin, in the highlands of Ontario, and Quetico, in the Rainy river country, which are maintained chiefly to ensure a primaeval forest, to protect wildlife and to offer a recreation resort for the public.

Communications.—The waterways of Ontario, previously described, provide natural avenues of communication which have greatly aided the development of the province. But in addition to the waterways, the southern and closely peopled part of Ontario is gridironed with railways and roads, some U.S. lines also running through the southwestern portion of the province. The province has one-fourth of the total single-track mileage of Canada, about 10,463 in 1949. A portion of the mileage in the past had been constructed under the spur of municipal and provincial subsidies, and gradually many small lines were consolidated into great railway systems. Important in opening up the mining areas of northern Ontario was the provincially owned line known as the Ontario Northland railway.

In 1949 the province had surfaced roads totalling 58,645 mi., which then constituted more than one-third the total for the whole of Canada and partly explained why Ontario attracted more U.S. tourists than any other province. About 84% of this road mileage was surfaced with gravel and stone. Registered motor vehicles numbered 970,137.

ONTARIO, a city of San Bernardino county, Calif., U.S., 38 mi. E. of Los Angeles, at an altitude of 1,000 ft. It is served by the Santa Fe, the Southern Pacific and the Union Pacific railways. The population was 22,872 in 1950. It lies on a sloping plateau at the foot of Mt. San Antonio ("Old Baldy," 10,080 ft. high). Through the heart of the city and on up to the foothills runs famous Euclid avenue, a straight avenue 7 mi. in length and 200 ft. wide, with 4 mi. of grassed parkway. The Ontario International airport has ample runways to provide for the landing and take-off of the largest aircraft. Ontario has many diversified activities, which include packing plants and nurseries, manufacture of electric irons, citrus by-products, venetian blinds, clothing, plastic tile wallboard, handcraft commodities, etc. Ontario is in the heart of the citrus belt. The city was founded in 1882 by George and William Chaffey, and was incorporated in 1891. It is governed by a modified council-manager form.

ONTARIO, LAKE, the smallest and most easterly of the Great Lakes of North America, is bounded on the north by the province of Ontario and on the south by the state of New York. It is roughly elliptical, its major axis, 193 mi. long, lies nearly east and west, and its greatest breadth is 53 mi. The area of its water surface is 7,540 sq.mi.; and the total area of its basin, 34,640 sq.mi. Its greatest depth is 778 ft.; its average depth, much in excess of that of Lake Erie; and it is, as a general rule, free from outlying shoals or dangers.

Physiography.—On the north side of the lake the land rises gradually from the shore, and spreads out into broad plains, which are thickly settled by farmers. A marked feature of the topography of the south shore is what is known as the Lake ridge, or, as it approaches the Niagara river, the Mountain ridge. This ridge extends, with breaks, from Sodus to the Niagara river, and is distant from the lake 3 to 8 mi. The low ground between it and the shore is a celebrated fruit-growing district, covered with vineyards, peach, apple and pear orchards and fruit farms. The Niagara river is the main feeder of the lake; the other largest rivers emptying into the lake are the Genesee, Oswego and Black from the south side, and the Trent, which discharges into the upper end of the bay of Quinte, a picturesque inlet 70 mi. long, on the north shore, between the peninsula of Prince Edward, near the eastern extremity of the lake, and the mainland. The east end of the lake, where it is 30 mi. wide, is crossed by a chain of five islands, and the lake has its outlet near Kingston, where it discharges into the head of the St. Lawrence river between a group of islands. Elsewhere the lake is practically free from islands. There is a general surface current, down the lake toward the eastward, of about 8 mi. a day, strongest along the south shore, but no noticeable return current. As a result of its relatively great depth there are seldom any great fluctuations of level in this lake due to wind disturbance, but the lake follows the general rule of the Great Lakes of seasonal and annual variation. Its mean surface elevation above mean sea level, for a period of 68 years, is 246.09 ft., which is about 326.33 ft. below the level of Lake Erie. The lake never freezes over except near land, but the harbours are closed by ice from about mid-December to mid-April.

Ports.—The principal Canadian ports are Kingston, at the head of the St. Lawrence river; Toronto, where the harbour is formed by an island with improved entrance channels constructed both east and west of it; and Hamilton, at the head of the lake, situated on a land-locked lagoon, connected with the main lake by Burlington channel, an artificial cut. The principal U.S. port is Oswego, N.Y., where a breakwater has been built, making an outer harbour.

Commerce.—The commerce of Lake Ontario is limited in comparison with that of the lakes above Niagara falls, and is in general confined to vessels which can pass the Welland canal and the St. Lawrence canals; the harbours on the lake are planned to accommodate vessels limited to the size determined by the dimensions of the smallest locks, which are: length 270 ft., width 45 ft. and depth 14 ft. on sills. The commerce on the lake is generally confined to coal shipped from Rochester, Sodus bay, Little Sodus bay and Oswego to Canadian ports on the lake and U.S. and Canadian ports on the St. Lawrence river; to coal from Oswego to upper lake ports; to grain and other products shipped from upper lake ports through the Welland canal to the St. Lawrence; to lumber from Canadian ports; and to pleasure traffic.

Canals.—The Welland ship canal, between Port Weller, Lake Ontario, and Port Colborne, Lake Erie, was opened to navigation in 1931. It permitted the large lake vessels operating on the upper Great Lakes to enter Lake Ontario. (*See* NIAGARA RIVER.)

The Erie and Oswego canals, built and operated by the state of New York, became important water outlets from Lake Erie and Lake Ontario to the Hudson river and to New York city. The canal is 12 ft. deep and is designed for use by boats drawing 10½ ft. The canal distance from Oswego to New York city is 338 mi. The Murray canal extends from Presqu'ile bay, on the north of the lake, to the head of the bay of Quinte, and enables vessels to avoid 70 mi. of open navigation. It is 11 ft. deep below the lowest lake level and has no locks.

Trent canal is the term applied to a series of rivers and lakes connected by short canals, designed to form a continuous system of light-draught navigation between Lake Ontario and Georgian bay, Lake Huron. The system in 1948 ran from Trenton to Peterborough lock, Peterborough, 88.74 mi.; Peterborough lock to Swift Rapids, 135.71 mi.; Swift Rapids to Big Chute, 8 mi.; Big Chute to Port Severn, 8.11 mi.; Sturgeon lake to Lindsay (Scugog branch), 10 mi.; and Lindsay to Port Perry (Scugog branch), 25 mi. There were 44 locks in the system.

At Kingston the Rideau canal, extending 123.53 mi. to Ottawa, enters the St. Lawrence river at the foot of the lake. This canal has 47 locks, with minimum dimensions of 134 ft. by 33 ft., and a depth of 5 ft.

Proposals for the construction of a St. Lawrence seaway power and navigation project were being considered at mid-20th century by the United States and Canadian governments.

ONTENIENTE, a town of eastern Spain, in the province of Valencia; on the right bank of the Clariano or Onteniente, a subtributary of the Júcar, and on the Játiva-Villena railway. Pop. (1940) 11,712 (mun., 13,564). Onteniente has a parish church remarkable for its lofty square tower, and a palace of the dukes of Almodovar. Linen and woollen cloth, paper, brandy, furniture and earthenware are manufactured.

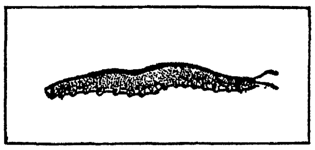
ONTOLOGY, the name given to that branch of philosophy which deals specially with the nature of being, *i.e.,* reality in the abstract. The idea, denoted in modern philosophy by the term "ontology" in contrast to the broader "metaphysics" and the correlative "epistemology," goes back to such phrases as ὄντως ὄντα, which Plato uses to describe the absolute reality of ideas; Plato, however, uses the term "dialectic" for this particular branch of metaphysics. Aristotle, likewise, holding that the separate sciences have each their own subject matter, postulates a prior science of existence in general which he describes as "first philosophy." So far, therefore, the science of being is distinguished not from that of knowing but from that of the special forms of being: as to the possibility of objective reality there is no question. A new distinction arises in the philosophy of Christian Wolff who first made "ontology" a technical term. Theoretical philosophy (metaphysics) is by him divided into that which deals with being in general whether objective or subjective, as contrasted with the particular entities, the soul, the world and God. The former is ontology. This intermediate stage in the evolution of the science of being gave place to the modern view that the first duty of the philosopher is to consider knowledge itself (*see* EPISTEMOLOGY), and that only in the light of conclusion as to this primary problem is it possible to consider the nature of being. The evolution of metaphysics has thus relegated ontology to a secondary place. On the other hand it remains true that the science of knowing is inseparable from, and in a sense identical with that of being. Epistemological conclusions cannot be expressed ultimately without the aid of ontological terms *See* KNOWLEDGE, THEORY OF; METAPHYSICS; PHILOSOPHY AND PHILOSOPHICAL STUDIES.

ONYCHOPHORA, a small but unusually interesting group of animals of the phylum Arthropoda (*q.v.*), differing in so many important respects from all other Arthropoda that a special class has been created for them. The class Prototracheata or Onychophora, containing only about 110 species, is equivalent in rank to the classes Crustacea, Insecta, Diplopoda, Chilopoda and Arachnida, although these groups contain thousands of genera and species.

A small group of genera which necessitates the creation of a separate class is usually the recipient of particular interest, for it will present highly important indications of the evolutionary relations between other groups of the animal kingdom. It is often to be regarded as the survivor of a group more extensive in range and more numerous in species and individuals in past times.

The Onychophora is such a case. It presents features which are typically arthropod. At the same time it possesses nephridia which recall the segmented worms (Annelida, *q.v.*), the group to which the Arthropoda are structurally most closely related. It may be relict of the evolutionary transition between these groups, as a fossil genus, *Asheaia,* has been discovered in deposits of Cambrian age.

The Onychophora contains only seven genera but these are so much alike that it is still common to use the term *Peripatus* as the generic name for all. The different species resemble each other externally so closely that, but for the differences in the number of legs, a picture in black and white like fig. 1 would stand for any of them. Notwithstanding this resemblance it appears necessary to restrict the use of the old generic name *Peripatus* to a few species.



AFTER SEDGWICK

FIG. 1.—PERIPATOPSIS CAPENSIS, DRAWN FROM LIFE, LIFE SIZE

The geographical distribution of the group is very wide but discontinuous and very local. Species occur in the West Indies, western Mexico, Central America, northern South America and Chile, South Africa, Malaya, India, Melanesia and Australasia.

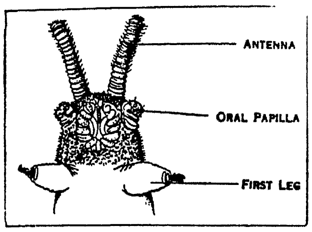
Specimens are only met with here and there, even where favourable conditions exist over a wider area. This discontinuity of occurrence coupled with the obviously poor powers of distribution of these creatures is strong evidence to indicate a group on the way to extinction. The distribution of the genera, which form two families, Peripatidae and Peripatopsidae, is as follows: *Peripatus*—America; *Eoperipatus*—Indo-Malaya; *Peripatoides* and *Oöperipatus*—Australia; *Opisthopatus*—Chile and South Africa; *Paraperipatus*—Malaya; *Peripatopsis*—central Africa.

Since the present account is a short general summary we shall continue to use the term "Peripatus" to include all species of the group. It will be understood, however, that this is for convenience only.

The animal is always found in moist situations (although the district itself may not be moist during the whole year). It is generally found under rotting branches lying on the ground, under stones, under bark and in the crevices of tree stumps. It is extremely sensitive to a dry atmosphere (specimens frequently will not withstand 24 hr. in a dry cardboard box, whereas they will be happy for many days in a small glass tube containing moist soil although the tube may be tightly corked). It never comes out into daylight and in captivity is much more active at night. It is probably carnivorous, feeding on small insects and other small animals in slime which it secretes.

Peripatus is a segmented animal, and at a first glance looks

somewhat like a caterpillar; but the long antennae, the peculiar body-surface and the legs soon dispel that view. The actual segmentation is shown externally only by the occurrence oı paired legs, one pair to each segment. The surface of the body is marked by ring-like ridges, 12 or 24 to each segment. Some of these are almost continuous round the circumference of the animal (they are all broken by a fine groove down the middle of the dorsal surface), others are less complete and arise between the former. The skin and body wall is highly characteristic, the superficial cuticle being very thin (as in the worms, in contrast to the usual arthropod condition) and raised everywhere on the ridges into delicate microscopic papillae. These close papillae give the skin a velvety appearance and their presence makes it difficult to wet the creature. The colours of these animals are dark gray, olive green, or brown to brick red above, and light, often almost white, on the under surface. Some species are uniformly coloured; others present distinct colour patterns, usually of lozenge-shaped spots Those of the western hemisphere are usually slightly patterned and the old world species show more contrasting colours.



FROM SEDGWICK IN "TEXTBOOK OF ZOOLOGY" (G. ALLEN & UNWIN)

FIG. 2.—VENTRAL VIEW OF HEAD OF P. CAPENSIS

Both head- and tail-ends taper and there is no distinct head. The anterior end bears two characteristic antennae, very mobile and extensible. In fact the whole animal is remarkably extensible and there is a great difference in length between a living specimen in motion (especially if this is rapid) and one in spirit.

Slightly posterior and ventral to the antennae are two small blunt oral papillae, and between these the buccal cavity is situated (fig. 2). An anal aperture is found at the extreme posterior end of the animal and further forward on the ventral surface between the last pair of legs is the reproductive aperture in both sexes. The males may sometimes be distinguished from the females by slight differences in the appearance of the genital opening. In many cases, however, the only difference, not always distinct, is the presence of little apertures of crural glands on the legs of the male (fig. 3).

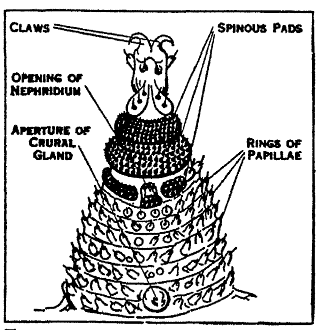


FIG. 3.—FOURTH LEG OF PERIPATOIDES (MALE)

The other apertures on the surface of the body are those of the tracheae (respiratory organs—*see* below) and the excretory organs. None of the former can be seen with the naked eye and only four of the latter, on the 4th and 5th pairs of legs (fig. 3).

The limbs of Peripatus are characteristic. Each consists of a cone-like stumpy leg bearing distally a narrower foot which carries two sickle-shaped claws. The skin of the legs bears rings of tiny papillae like those of the body and near the apex there are spinous pads. The structure of the appendages is thus quite unlike the jointed arthropod leg.

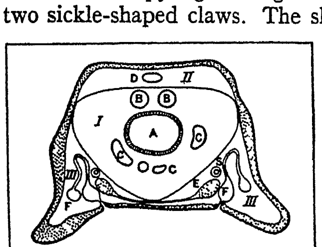

FIG. 4.—DIAGRAM OF TRANSVERSE SECTION THROUGH MIDDLE OF BODY OF PERIPATUS

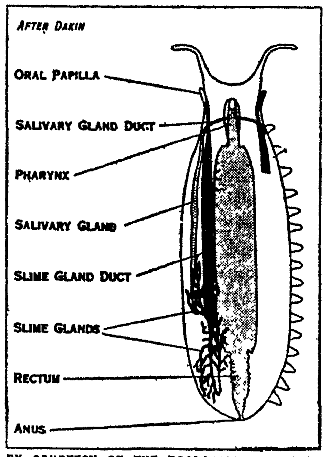
Internal Structure.—A transverse section through an adult shows clearly how the body cavity, which is a haemocoele, is subdivided by delicate sheets of tissue (fig. 4) into (I.) a large central space extending the whole length and containing the gut (A), slime glands (B) and reproductive organs (C); (II.) a shallow dorsal space above the central cavity, containing the heart (D); (III.) two lateral spaces each with a nerve cord (E), nephridia (F), and salivary glands (S). The excretory organs are also found in these compartments, especially in the extensions which exist in the legs.

The *Alimentary Canal.* The buccal cavity contains a pair of horny jaws (fig. 5) which may just be seen from the exterior. Each consists of two cutting plates lying in contact. These jaws are the only mouth appendages present. The mouth at the posterior end of the buccal cavity leads into a short, muscular pharynx and from this a short oesophagus opens into the stomach (fig. 5). This forms the greater part of the alimentary canal. It is a straight and wide tube leading almost to the posterior end where a short, narrow rectum opens at the terminal anus.



BY COURTESY OF THE ZOOLOGICAL SOCIETY

FIG. 5.—PERIPATOIDES OCCIDENTALIS, SHOWING PARTS

The only glands connected with the alimentary canal are two salivary glands (fig. 5) which open by a common duct into the buccal cavity. Each gland is a long tubular structure lying in a lateral cavity close to the nerve cord.

The *Slime Glands* (fig. 5) are another peculiar feature. There are two of these, each opening on an oral papilla. Each consists of a long dilated tube which acts as a reservoir and lies over the stomach in the central cavity of the body. This reservoir extends back a considerable distance and then gives off numerous diverticula in which the slime is secreted. These diverticula lie around the posterior part of the stomach, often entangled in the coils of the reproductive organs. When a living specimen is touched the slime is shot out from the oral papillae to a distance of several inches. Contact with the air causes it to congeal into white, sticky threads. It is supposed that the substance is used for offence or defence.

The *tracheae* are among the most noteworthy features of the Onychophora because they are characteristic of certain other Arthropoda. They arise in bunches from the bottom of little epidermal pockets, tracheal pits. It is impossible, however, to see these pits externally. From each pit a large or small bunch of parallel tracheae start off, without branching; then they separate and finally branch, when they reach the organs they supply. Since the small single tubes require a high magnification to see them, one can only see readily the little rosettes of tubes where they are bunched at the tracheal pits and then only by examining the internal surface of the body-wall in fresh specimens.

The tracheal pits are numerous and arranged in definite positions. In the West Australian species there are two main rows, one on each side, between the mid-dorsal line and the level of the legs. There are also four longitudinal series on the ventral surface. E. Gaffron stated that there were about 75 openings to a segment in *P. edwardsi.* The present author has counted 32 without difficulty in *Peripatoides occidentalis.* The tracheal tubes have a spiral thickening in the walls similar to that in other Arthropoda.

The *excretory organs* are probably the most surprising of all the structures found in this animal and at once call to mind the annelid worms, being not at all like the excretory organs of the arthropod groups. They are paired structures, one pair to each pair of legs. With the exception of those of the 4th and 5th pairs, each excretory tube opens on the ventral surface at about the point where its corresponding leg joins the body. The 4th and 5th pairs open on papillae near the distal end of the corresponding legs (fig. 3). It is a striking fact that this distinction should be found constantly in the different genera.

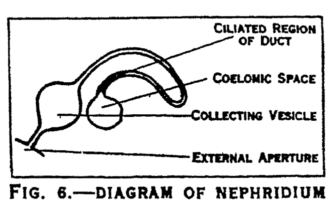


FIG. 6.—DIAGRAM OF NEPHRIDIUM OF PERIPATOIDES OCCIDENTALIS

The excretory organs have been termed *nephridia* and there is some evidence from embryology in support of this. Anatomical study, however, is insufficient to indicate the exact homologies of

these organs and the embryological evidence requires confirmation. Each "nephridium" (fig. 6) consists of a tube with an enlargement, the collecting vesicle, near its aperture and another, corresponding to a coelomic cavity, at its internal blind end. In the West Australian *Peripatoides* W. J. Dakin discovered that cilia were present in that part of the tube leading out from the coelomic vesicle. This is the second part of the body where cilia have been found in these animals and since cilia are characteristically absent in the Arthropoda, it is a point of importance. Their other site is the reproductive organs of the female.

The *blood system* appears to consist only of a feebly developed dorsal tubular heart.

The *nervous system* consists of a pair of large supraoesophageal ganglia completely united in the middle line and occupying most of the head space, and a pair of cords which run backward. These latter, instead of being close together in the mid-ventral line, are situated at the sides in the lateral cavities of the haemocoele. Numerous commissures, 8–10 between successive pairs of legs, connect the lateral cords. There are indications of ganglia, corresponding to the legs in number, where the lateral cords are slightly thickened. Nerves pass out from the supraoesophageal ganglia to the tentacles, eyes and skin sense organs and also leave the lateral nerve cords.

The only sense organs are the eyes and numerous skin sense organs all of which look alike in structure.

The eyes are moderately well-developed, situated on the head near the base of the antennae. They are simple eyes, not compound like those so characteristic of the Arthropoda. They differ also fundamentally from the arthropod type of simple eye, the ocellus. It is sufficient here to point out that on the whole the visual organ presents features of a simple type met with in both annelid worms and arthropods, but it has followed its own line of evolution.

The skin sense organs consist of little packets of cells associated with a projecting spine. They look like and are usually regarded as tactile organs. Peripatus is, however, extremely sensitive to chemical stimuli as well as to vibrations and the presence of a very little chloroform vapour or acetic acid in the air produces a quick reaction.

Reproduction.—The sexes are separate. The reproductive organs consist of a pair of tubular testes in the male and a pair of ovaries in the female. In both sexes the reproductive organs are continuous with the tubes which lead their products to the exterior, opening at the single aperture already described. In the female, part of each duct is differentiated to form a uterus in which the young develop. Slight differences in the arrangement occur in the different species. Almost all produce living young.

One feature of special note is the varying amount of yolk in the eggs and its result. The Australian species have large yolk-laden eggs, and all species come near to laying eggs. At least one species of eastern Australia is actually oviparous and eggs are laid in sculptured shells. In all others the eggs are retained within the female and after a period of several months the young are born.

The South African and Australian species give birth to the young in April–June. Fertilization in one of the latter species takes place in the preceding August or September and the period of gestation would thus be 8–9 months. It has been given as 13 months for the Cape species.

The eggs are fertilized internally and it has been stated that the male of the Cape species deposits its spermatozoa on the surface of the female. Since the uterus is said never to contain spermatozoa, the mode of entrance into the body would be a complete mystery. There can be no doubt that in the Australian species copulation of the two sexes takes place and the spermatozoa pass up the vagina of the female.

The embryology of the Cape species has been worked out and reference should be made to A. Sedgwick (*see* below) for details. Further work is required in this direction and would be of undoubted interest and importance.

ONYX, a striped agate in which white layers alternate with black. When brown or red bands occur instead of black the stone is termed sardonyx (*see* SARD AND SARDONYX). The Romans applied this name originally to a species of marble, now called onyx marble, because of a resemblance between its well-defined white and yellow veins and the shades in the fingernail (ὄνυξ). When this marble became less important the name was transferred to the striped agate. Onyx has always been largely employed in cameo work because the design and background could be cut so as to occur in differently coloured layers. The best cameos are those produced by the ancients, though a revival of the art was occasioned by the discovery in the middle of the 19th century of the South American sources of onyx. Many inferior agates are now made suitable for the cutting of cameos by artificially dyeing the layers (*see* AGATE) and glass imitations are also extensively produced. Beads, brooches, ring stones and other small ornaments are frequently made of onyx and larger pieces are fashioned into cups and vases. Onyx marble is much softer and less precious than true onyx and includes the following ornamental stones; Mexican onyx or Tecali marble, which is often of a delicate green shade, Algerian onyx and Gibraltar stone.

The chief localities for onyx are South America and India.

See C. W. King, *Precious Stones, Gems and Precious Metals* (London, 1865); A. Eppler, *Die Schmuck und Edelsteine* (Stuttgart, 1912). For onyx marbles *see* G. P. Merrill, *Rep. U.S. Nat. Mus. for* 1893 (1895). (W. A. W.)

OOLITE, a geological term used in two senses; the commonest use refers to a particular type of structure common in limestones and ironstones, where the rock is composed of small rounded grains, resembling the roe of a fish (Gr. ὤον, an egg, λίθος, a stone). This structure is apparently produced in more than one way, most commonly perhaps by accretion of $CaCO_3$ from solution in water around tiny sand grains or shell fragments in moving water, where the grains are kept in constant motion. Grains formed in this way show radial or concentric crystalline structure when cut open. In some instances the grains are merely minute rounded pebbles of an older limestone, and such may show no particular structure. Many fine examples of oolitic deposits are formed by calcareous algae in hot springs, as at Carlsbad and Vichy. Such grains consist of aragonite, not calcite. Oolitic ironstones are apparently formed in a way similar to that first described, but the exact manner of precipitation of the iron is still somewhat doubtful. Bacteria may play a part.

The second use of the term is stratigraphical, to indicate the British rocks forming the middle and upper divisions of the Jurassic system (*q.v.*) where oolitic rocks are common. This usage is now out of date. (R. H. RA.)

OOLOGY: *see* EGG.

OOTACAMUND, town, British India, headquarters of the Nilgiris district in Madras, approached by a rack railway from Mettupalaiyam station on the Madras railway. Pop. (1941) 29,850.

Ootacamund is the principal sanatorium of southern India and summer residence of the governor of Madras and is noted for hunting, fishing and shooting. It is placed on a plateau 7,220 ft. above the sea, with a fine artificial lake, and mountains rising above 8,000 ft. The mean annual temperature is 58° F., with a minimum of 38° in January and a maximum of 76° in May; mean annual rainfall, 49 in. The houses are scattered on the hillsides amid luxuriant gardens. In the neighbourhood are plantations of coffee, tea and cinchona. The Lawrence Memorial school for the children of European soldiers was founded in 1858.

OPAH (*Lampris luna*), a pelagic fish of the order Allotriognathi. The body is compressed and deep, with minute scales. A dorsal fin, high anteriorly, runs along nearly the whole length of the back; the caudal is strong and deeply cleft, for rapid swim-

ming. The pelvic fins contain numerous (15–17) rays. In its gorgeous colours the opah surpasses even the dolphin. The fins are bright scarlet, and the sides bluish-green above, violet in the middle, red beneath, variegated with oval spots of brilliant silver. Its home is the Atlantic, especially near Madeira and the Azores. It occurs also in the Pacific, and is rare in the Mediterranean. It grows to a length of 4 to 5 ft. and a weight exceeding 100 lb.

OPAL, a mineral, in chemical composition an amorphous hydrated silica, some forms of which are highly prized as gems. Many varieties of opal (Lat. *opallus*, Gr. ὀπάλλιον) are recognized but of these few have any value as gem stones. The most beautiful is precious opal which displays a wonderful scintillating coloured brilliance, known as opalescence. In early times it excited the keenest admiration, witnessed by Pliny's enthusiastic description, "For in them you shall see the living fire of the ruby, the glorious purple of the amethyst, the green sea of the emerald, all glittering together in an incredible mixture of light." Orange or yellow stones which exhibit opalescence are called fire opals. Black opals are stones in which the background is extremely dark. Really black stones are extremely valuable and rather rare. Common opal is a term applied to the varieties which do not exhibit opalescence. Most of the names applied are self-explanatory; *e.g.,* milk opal, resin opal, liver opal, agate opal, etc. Prase and jasper opals are green and red respectively. A curious, very porous variety, which can absorb surprising quantities of water, is called hydrophane. It will adhere to the tongue. It is almost opaque when dry, but becomes practically transparent when saturated with water. Another porous variety is cachelong, which has a lustre like mother of pearl.

Opal is the silicious material of the tests of radiolaria and the frustules of diatoms. These may accumulate as deposits of tripoli or kieselguhr, used for polishing. Opal is often found as pseudomorphs after gypsum, glauberite, calcite and other minerals. Pseudomorphic aggregates are sometimes known as pineapple opal. Opal has been discovered in a fibrous form much like asbestos, from which it may be distinguished by its harsh touch.

Occurrence.—Opal is widely distributed as nodules and stalactitic masses in the cavities of volcanic rocks, deposits from hot springs, etc. It is deposited as a gel or sol. Precious opal is found only in a few places. Cserwenitsa in Hungary was for long the only source; probably all the ancient stones were found there. Since the discovery of the rich fields in Australia, the Hungarian mines have lost most of their importance. The discovery of opals at White Cliff, New South Wales, was followed in a few years by the field on the boundary between New South Wales and Queensland. Many "black opals" are found there, but truly black stones are found at Lightning Ridge. The black opal has been thus described: "It combines the iridescence of the dewdrop with the colour of the rainbow, set in the blackness of night. It is a smothered mass of hidden fire." Precious opals have been found in Hōsako, Japan, which are nearly colourless and transparent with a bluish tint, and show a change rather than a play of colours, from emerald green to apple red. Esperanza, Queretana and Timapan in Mexico are noted particularly for fire opals (girasol). A fine mass of precious opal was found in Nevada.

Coloration.—Pure opal, which is colourless, is rarely found. It is usually stained dull colours by ferric oxide, alumina, lime or magnesia. That the coloration is not ordinary absorption is shown by the fact that the transmitted light is complementary to the reflected. If for example a blue stone is held up to the light, it appears yellow. The opalescence is not due to any pigmentation, but to the fact that as the original gel dried and cooled it became riddled with cracks, which were subsequently filled up by another gel containing a different amount of water. The resulting heterogeneity of the opal gives it a varying refractive index, which affects the light in the same way as a soap bubble. The thinner and more uniform the cracks the greater the splendour of the colours, the shade depending on the direction in which it is viewed. In the variety known as harlequin opal the rainbow colours are flashed from little angular surfaces forming a mosaic.

Opals are usually cut *en cabochon.* If they are too thin for this, they are used for inlay work, and if scattered in small pieces throughout the matrix, they are sold as such, under the name "root of opal." Fire opal shows to best advantage if facetted. Opal is not placed among the most precious of stones because of its softness, but Pliny placed it after the emerald. He relates that Mark Antony exiled a rich senator, Nonius, for the sake of an opal the size of a hazel nut. Many superstitions have centred around opal, and even in modern times it has been regarded as unlucky.

Properties.—Opal contains from 3%–13% of water, precious opal between 6% and 10%. It is soluble in caustic alkalies, and when mixed with soda easily fusible. It is soft, 5.5–6 on Mohs' scale, and is therefore easily scratched. It is brittle and has a conchoidal fracture. Opals are porous, and it is dangerous to immerse them in liquids. Normally opal is isotropic, but owing to internal strains it is sometimes doubly refracting. The refractive index ranges from 1.444 to 1.464. They are said to be more brilliant on warm days, but a high temperature, by withdrawing water, destroys their value. Milk opal has been coloured by oils and pigments to imitate the rare blue and dark red stones. The colour is fixed with Canada balsam.

See A. Eppler, *Die Schmuck- und Edelsteine* (Stuttgart, 1912); G. F. Herbert Smith, *Gemstones* (London, 1926). (W. A. W.)

OPAVA (German, *Troppau*), Czechoslovakia, lies on the Opava, a tributary of the Oder, in the middle of a wide fertile plain. The old town, founded in the 13th century, is girdled by parkland beyond which stretch extensive suburbs of the new town, in which are centred the industries (brewing, sugar refining, cloth and industrial machinery). Pop. (1930) 36,030, mostly German. In 1938 the town was ceded to Germany by the pact of Munich; it was returned to Czechoslovakia in 1945.

OPELIKA, a trading and industrial centre of eastern Alabama, U.S., county seat of Lee county; on federal highways 29 and 241, served by the Central of Georgia railway and the Western Railway of Alabama. Pop. 12,264 in 1950 and 8,487 in 1940. Founded in 1773; incorporated 1858.

OPELOUSAS, a city of southern Louisiana, U.S., capital of St. Landry parish; 130 mi. W.N.W. of New Orleans, on the Missouri Pacific, the Southern Pacific and the Texas and Pacific railways and truck and bus lines. Pop. (1950) 11,600. It has a meat packing plant, cottonseed mill and refinery, large outdoor-advertising factory, cracking plant for oil products, moss and cotton gins, saw mills, a broom and mop factory, ice factories, bottling works and a brick factory.

OPEN BILL. A curious stork (*q.v.*) of the genus *Anastomus,* so called from the formation of the lower mandible, which is hollowed out so as to meet the maxilla at the base and tip. There is an African and an Indian species.

OPEN-FIELD SYSTEM. The "open" or "common" field was a characteristic feature of manorial agriculture (*see* LAND TENURE: ECONOMIC AND AGRARIAN ASPECTS). It had its origin, however, in primitive conditions long antecedent to the development of feudalism. Three or four centuries before the Roman occupation the Celtic inhabitants of Britain had evolved a system of co-operative tribal husbandry on the open-field system. The cultivated, or arable, land occupied by the kindred, or tribe, was divided into narrow strips separated by balks of turf. The strips were about a furlong in length and of varying widths. The length of the strips became more or less standardized at an early date, as the disadvantage of irregular lengths for adjoining strips became obvious. The furlong—clearly "furrow-long"—is generally agreed to have represented the distance which oxen would conveniently plow at a stretch, and the plowman could keep a fairly straight line. Persistent trial and error resulted in the general acceptance of the most suitable length which when once adopted became the standard enforced by tradition. The width of the ordinary strip was, in like manner, gradually fixed at four times the length of an oxgoad, which was $5\frac{1}{2}$ yd. Land measurements were no doubt not very exact in those days but the result was eventually to establish the standard size of the strip at approximately 220×22 yd., or in other words an acre.

In the Celtic open-field each free tribesman was allotted five strips. The allocation of the strips was made in accordance with strict tribal regulations, and the cultivation of the land was carried out co-operatively.

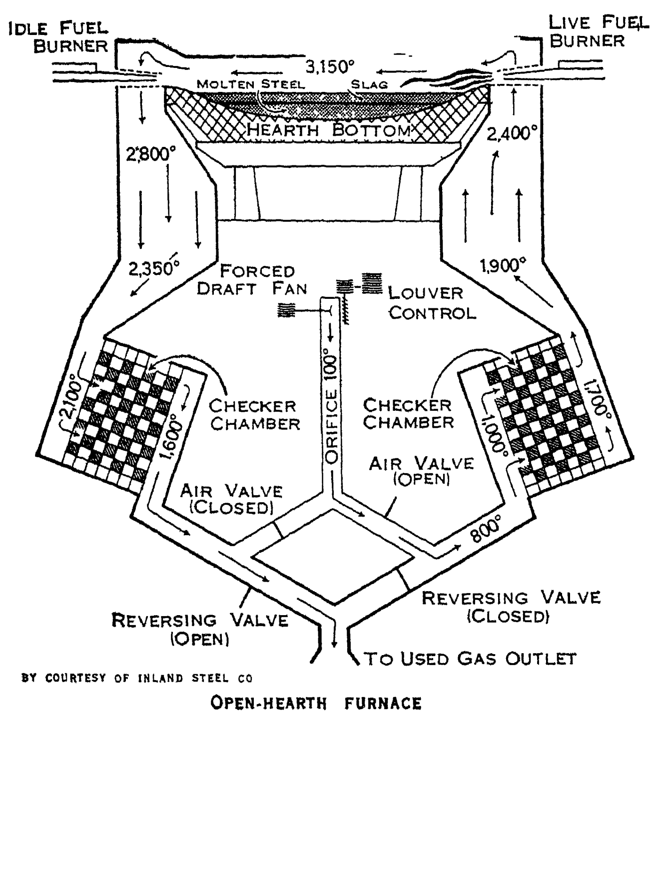
The plow was common property but the oxen appear to have been individually owned.

This system fitted very readily into the manorial organization introduced by the Normans. The status of the cultivators was changed, but the open-field with its separate acre or half-acre strips and its co-operative methods of husbandry continued. The administration of the manor became in form autocratic and the land was held in servile tenure, but in practice the rules governing the allocation of the strips and the cultivation of the land were settled by the tenants. Gradually the rigidity of the manorial organization broke down, the relations of lord and tenants were changed and only the forms of feudalism lingered. But the open-field system survived in thousands of parishes until the wholesale enclosures of the end of the 18th and early part of the 19th centuries abolished it generally, although it lingered in isolated cases until the beginning of the 20th century. Indeed at least two open-fields—at Laxton in Nottinghamshire and Braunton in Devon—continued to exist after that time. (R. H. R.; X.)

OPEN-HEARTH STEEL PROCESS. The idea that steel could be made from pig iron by oxidizing carbon with iron ore, using the regenerative principle for preheating gaseous fuels, was proved in 1868 by Karl Wilhelm Siemens, a naturalized British citizen of German birth. The Martin brothers of France substituted scrap for ore in the Siemens process, which reduced the extent of oxidation required. Open-hearth furnaces in Europe today are called Siemens-Martin or Martin furnaces. Of the additional modifications made since the Martin brothers, the Talbot (duplex) process proved the most important. This furnace is a tilting open-hearth, which refines molten metal which has had carbon removed in an acid converter. Although only a small percentage of open-hearth steel is made by this process today, it is useful during scrap shortages and for removing phosphorus from molten metal, which cannot be removed in the converter.

The modern open-hearth plant is usually made up of 9 to 12 furnaces arranged side by side. The trend is toward larger furnaces ranging from 200 to 275 tons, with a cost of more than $4,000,000 per furnace, including auxiliary equipment. An open-hearth furnace with a capacity of 550 tons per heat was built at Weirton, W.Va.

Modern open-hearth furnaces are of the reverberatory type and have a hearth in the shape of a large, oval dish, as the accompanying diagram shows. At each end of the furnace are ports where the fuel and air meet; these are connected to the refractory checkers—regenerators—by flues. Through a system of valves and flues,



BY COURTESY OF INLAND STEEL CO

OPEN-HEARTH FURNACE

the checkers are connected either to the incoming air supply or the stack for waste gases. Utilization of heat from waste gases is made possible by these valves, which change the direction of the flow of air and gases automatically about every 15 min. to maintain a checker temperature of from 1,800° to 2,200° F., which is required for efficient operations.

Oil, tar, natural gas and coke-oven gas are the most common fuels used in the U.S. in open-hearth furnaces. To obtain high enough flame temperature and economic fuel consumption, the air supplied for combustion is always preheated, and when gases of low British thermal unit (B.T.U.) values, such as producer gas, or blast-furnace gas enriched with coke-oven gas, are used as fuel, these are also preheated. Since a large number of furnaces were designed originally for producer gas, they were built with two regenerators at each end of the furnace, a small one for gas and a large one for air. The majority of these furnaces were converted for high-B.T.U.-value fuels and use all chambers for heating air. Modern furnaces which are not designed for use of a gas requiring preheating are built with only one chamber for air at each end.

Fuel consumption, using hot metal (molten pig iron) and scrap, varies from 2,850,000 to 4,800,000 B.T.U. per ton of steel produced. Oxygen, used by some open-hearth plants for flame enrichment, increases the flame temperature and reduces the quantity of combustion gases produced, which in turn reduces the heat loss in flue gases.

Except for the hearth, the refractory material used in building an open-hearth is about the same for acid or basic types. Both use silica-brick roofs, which will withstand temperatures up to 3,100° F. A typical basic hearth is made up of insulating brick and magnesite or chrome brick covered with magnesite and dolomite. Chrome brick is also frequently used to separate the bottom and roof because of its neutral chemical properties. In the acid hearth, silica brick and silica sand are used.

The basic open-hearth charge usually consists of limestone, steel scrap and pig iron (molten or cold). Charges vary from nearly 100% scrap with very little pig iron to 100% hot metal. The most widely used charge in the United States is one consisting of 40% to 65% hot metal and 35% to 65% scrap. When the hot-metal portion exceeds about 55%, enough iron ore is charged to oxidize part of the carbon and other impurities from the hot metal. A violent reaction (ore boil) takes place when the hot metal is added to this type of charge, which produces a flush slag containing about 30% iron, 22% silica, 3% aluminum oxide, 20% calcium oxide (lime) plus magnesium oxide, 1% phosphorus, 8% manganese and 0.1% sulphur. This slag, which accounts for about 5% metallics lost, is run off into slag ladles. The next step in the process is the lime boil, which is caused by calcination of the limestone. The lime (CaO), which comes to the surface, makes the second slag for the above operation and the first slag for heats that make use of less than 55% hot metal. During the lime boil and refining period, lumpy iron ore is added to furnish available oxygen to oxidize the carbon, silicon and phosphorus from the molten bath. Carbon is liberated as carbon dioxide, and the latter two are held in the slag in the form of calcium compounds. Oxygen, supplied through a lance injected into the molten bath, was used in some open-hearth plants to supplement iron ore. Fluorspar is added to thin the slag (break up lumps of lime) to make it more adaptable to hold silicon, phosphorus, and other impurities.

Removal of sulphur is one of the most serious problems in the open-hearth as well as the entire steel industry. It enters the bath as a constituent in most raw materials, as well as from the flame. Large slag volumes, high slag basicity, and fluid slags with good bath action tend to aid desulphurization. High temperatures aid in promoting fluidity and motion.

When all the above impurities have been removed, the desired carbon content is reached, and the temperature is correct (2,850°–3,000° F.), the melt is tapped and cast into ingots or castings. Adjustments to meet specification are made by adding ferroalloys to the furnace before tapping and to the ladle during tapping. In the acid process the elimination of sulphur and phosphorus is not possible. The basic slag, essential to the removal of these impurities, cannot be used in the acid-lined furnace without injury to the

acid (silica) lining. Oxidation of the carbon is accomplished in the same manner as in the basic process. To produce good steel, therefore, it is necessary to use raw materials low in impurities in the acid process.

In the early 1950s approximately 90% of the steel made in the United States was produced in open-hearth furnaces. The annual ingot capacity of the United States steel industry, as reported by the American Iron and Steel institute, was 117,500,000 net tons as of Jan. 1, 1953, of which open-hearth furnaces supplied 102,700,000 tons. OPERA, a dramatic work in which the words, instead of being spoken in verse or prose, are wholly or partly sung to an instrumental accompaniment almost invariably assigned to an orchestra of variable size. The music of an opera may be divided into separate, formal pieces for single or combined voices (arias, concerted numbers), and sometimes for instruments only (interludes, dances), connected either by spoken dialogue or by sung recitative; or it may be composed continuously in a more or less symphonic manner, with structural sections still discernible or entirely submerged in an organization spread over whole acts. Whatever the composer's procedure, which depends partly on his individual disposition and partly on his place in operatic history, there must be musical structure of some kind in opera.

The question of the relative importance of the various elements found in opera cannot be better expounded than by quoting from Sir Donald Tovey's article on this subject in an earlier edition of the *Encyclopaedia Britannica:*

"... here we may profitably consider what are the qualities necessary for success in opera. It is notorious that the absolute value of the music comes last, if it is a factor of success at all. Unquestionably it is a factor in immortality; and the music of *Idomeneo* is immortal, though that opera is revived only in Mozart festivals. But operas cannot wait for immortality, and can manage on quite flimsy music to achieve as much immortality as musical history has given time for. It might be thought that success depends on dramatic power; and this is nearer the truth. But dramatic power comes only third in the conditions, and coherence is not necessary at all.

Two qualities take precedence of dramatic power as conditions for success in opera; one is the theatrical sense, and the other the histrionic sense. They are inseparable but not identical. The theatrical sense can thrill the listener before the curtain rises, as in the modulation to F major at the end of the overture to *Don Giovanni;* the histrionic sense can save the stage-manager the trouble of telling the actors what to do with their hands. . . ."

Beginnings.—The opening date of the history of opera can be conveniently placed in the year 1600, when J. Peri's *Euridice* was produced at Florence, though he had already brought out his setting of O. Rinuccini's *Dafne* in 1597. But opera has a long prehistory, which it is not too far-fetched to trace back to Greek tragedy of the Periclean age, portions of which were undoubtedly sung. The share music may have had in the Roman theatre and in quasi-dramatic performance up to the middle ages is so uncertain as to be unprofitable to speculate upon, but we do know that the mediaeval church, from the 10th century onward, had an elaborate form of sacred music drama, performed on particular feast days by clergy in costume, with the chancel for a stage, and intoned in plainsong. Allowing for the conditions of the time, we may say that these performances had every feature of opera except that of instrumental accompaniment.

Italy.—Outside the church, and nearer the time of opera proper, performances of mystery and miracle plays made enough of music, now instrumental as well as vocal, to show distinctly operatic ingredients, and out of them grew in Italy a special type of acted oratorio or allegorical drama with music, the 16th century *rappresentazione.* The most famous and one of the last before opera came into its own was Emilio de' Cavalieri's *La Rappresentazione di anima e di corpo,* performed in Rome in Feb. 1600. The "soul" and the "body" of the title are impersonated by human characters, and so are various abstractions, such as virtues and vices.

The madrigal opera, of which O. Vecchi's *L'Amfiparnasso* of 1594 is the best-known example, anticipated by A. Striggio and others and imitated by A. Banchieri and others, cannot really be regarded as a direct forerunner of true opera, except in so far as it was in a kind of dramatic form; for modern scholarship no longer regards it as having been performed on the stage in dumb show, with the voice parts sung behind the scenes. Nevertheless, it must be taken into account, if only because it may have done something to discourage dramatic stage presentation with music of a highly wrought character. Composers who cultivated polyphony (the mass and motet in church, the madrigal and its forerunners in the polite world) left the stage alone, because their music could not be accommodated to dramatic action; and this gave a chance to musicians who were performers rather than creative artists to try their hands at dramatic pieces with words turned into song. Simplicity of treatment, which to the fully trained composers would have been an embarrassment, if not an impossibility, was an advantage to the dilettanti who gathered at Florence in the house of Count Bardi, an aristocratic patron of the arts. The most gifted of the musicians among them were V. Galilei, the father of Galileo, who however did not dabble in dramatic music, Peri and G. Caccini. It was not the art of composition in the first place that was felt by the Bardi *camerata* to be required for what they had in mind, which was nothing less than a revival of Greek drama as they imagined it; and in setting about to give shape to their imagination they did what the great composers failed to do—they produced opera for the first time in a form recognizably like that we still know today.

Three days after the production of Peri's *Euridice* came Caccini's *Il Rapimento di Cefalo,* and this composer made his new setting of *Euridice* for 1602. These pieces were feeble enough musically; the vocal line was little more than continual recitative and the accompaniments were played on whatever was available, from the sketchiest of scores; but as essays in the treatment of the voice for the purpose of eloquent and often truly dramatic declamation they were remarkable enough to exercise a decisive influence on the first great master of opera, Claudio Monteverdi, who was soon at hand. His *La Favola d'Orfeo* (Mantua, 1607), is in the declamatory style of the Florentines, with the difference that an artist is in charge for whom musical invention is important and who seizes every chance to insert organized musical pieces. An even greater work by Monteverdi is his last, *L'Incoronazione di Poppea* (Venice, 1642), interesting also for its treatment of a subject from history instead of mythology. We now see the two chief sources opened up from which serious opera during the 17th century was to draw its librettos exclusively.

Monteverdi's orchestra was still an *ad hoc* affair: the score remained incomplete, with the harmony indicated in the continuo part, and the general principle was that such instruments should be used as happened to be available. But we have a specification of what he suggested for *Orfeo,* extravagantly enough. At Venice, where Monteverdi moved from Mantua in 1613, he took his share in the establishment of opera for the first time as a public entertainment, as distinct from a court function. In his last years there were four public theatres in the city devoted to music. The chief Venetian composers succeeding him before 1660 were F. Cavalli, M. Cesti, P. Sacrati and the elder Ziani. Their works were elaborately spectacular, and there is small doubt that the stage machinery was regarded as more exciting than either the plot or the music, both of which were apt to stiffen into conventions which only in the best composers' best moments escaped being tedious. There was also public opera in Rome, with S. Landi, L. Rossi and D. Mazzocchi as the main musical figures. Nowhere else did it as yet flourish outside the courts.

Germany.—Meanwhile there had been an abortive beginning in Germany. An adaptation of Rinuccini's *Dafne* libretto by Martin Opitz was set as an opera by Heinrich Schütz and produced at Torgau in 1627. But Schütz was diverted into other activities and never again wrote an opera. No other German composer did for half a century, and even then there was only one public opera house in all Germany, at the free Hansa city of Hamburg, which had no court. The courts themselves cultivated Italian opera and some of them French a little later. Had it not been for the German princes, who vied with each other in keeping up luxurious

establishments, opera might easily have suffered the same neglect in Germany as in England, for it was from the courts that during the 19th century the municipalities of the larger towns gradually inherited the tradition that opera must be subsidized.

England.—The English neglect had various causes. The most potent cause was not a lack of composers to whom opera was congenial, but an overwhelmingly great school of spoken drama that flourished at the very time opera arose in Italy and produced verse drama in which the words often reached a splendour apt to make a perfectly satisfactory substitute for music. The commonwealth also had something to do with the stagnation of opera before Henry Purcell's maturity. All the same, the suppression was not complete. The masque, which in England had much the same influence on the musical stage as the ballet had in France, was well established, and what is called the first English opera, Sir William D'Avenant's *The Siege of Rhodes,* with music by M. Locke, H. Lawes, H. Cooke, E. Coleman and G. Hudson, was staged four years before the Restoration.

France.—In France tournaments and masquerades led to the immediate predecessor of opera, the court ballet, the most famous specimen of which, *Le Ballet comique de la reine* of 1581, already shows operatic elements. But the composer, Balthasar de Beaujoyeulx (Baldassare de Belgioioso) was Italian-born. It was long before the first real French opera appeared. It is sometimes claimed that this was the *Andromède* of 1650; but this was a play by Corneille in which the words immeasurably overtowered what was little more than incidental music, by C d'Assoucy. A better claim to priority is disputed by M. de La Guerre's *Le Triomphe de l'amour* (1655) and R. Cambert's *Pastorale* (1659). The latter is rather more important musically, but both pieces are pastorals, lyrical and spectacular, and both give as much scope to dancing as to drama. The earliest French operas had some influence in London, particularly those of Cambert, who went to live there.

In Paris the next great figure, indeed the first truly great one in French opera, was Jean-Baptiste Lully, again originally an Italian, Giovanni Battista Lulli of Florence, but belonging at least as much to French music as Handel later did to English. Nevertheless, it is significant that before him Italian opera was cultivated in Paris to some extent. Lully's musical technique is limited, and he avoided counterpoint except in the fugal allegro section of his overtures, where he created a type of instrumental piece that remained in force, by no means only in France, until well into the 18th century, even being used by Bach and Handel. On the other hand Lully had a great fund of graceful and sometimes pathetic melody, and he laid much stress, especially in his recitatives, on correct declamation of the French language, a difficult problem where so little syllabic stress occurs, and yet one to which so literary a nation as the French attached great importance.

It was in French opera that recitative first became sharply detached from set musical numbers, which had to be formally self-sufficient because they were not only rounded-off airs, but quite often dances. But French recitative was accompanied by the orchestral strings, whereas in Italian opera, which soon began to use it in even more strict separation from the formal numbers, it became relegated to the harpsichord that played the continuo throughout the opera, but in the recitatives was supported by bass strings alone.

The Later 17th Century.—During the last third of the 17th century, while France and Italy continued to build at opera in their several ways, with M. A. Charpentier, P. Colasse, A. Campra, H. Desmarets and A. C. Destouches as new figures in France and A. Draghi, B. Pasquini, A. Stradella and A. Steffani in Italy, there were some isolated events in Spain and Germany. J. Hidalgo in Madrid, J. Theile at Hamburg and Nicholas Adam Strungk (the younger Strungk) there and at Leipzig. H. J. F. von Biber at Salzburg brought out the first work by an Austrian (strictly speaking Bohemian) in 1687. But this still had an Italian libretto, and the court in Vienna had already patronized Italian opera on a lavish scale, with Cesti's *Il Pomo d'oro* (1666–67) as the most extravagantly spectacular work.

Two major figures now arose, the first opera composers whose work is capable of maintaining itself in the regular modern repertory. They were Alessandro Scarlatti in Italy and Henry Purcell in England. Born within less than a year of each other, they dominate this period, both by superior musical genius and Purcell, in addition, by a realistic foresight that penetrated far into the next century. He was hampered by texts which were in every case but one sadly nonoperatic, in the sense that they were merely plays containing an unusually large number of opportunities for musical settings. The exception was the small-scale *Dido and Aeneas,* the libretto of which, in spite of Nahum Tate's doggerel, enabled Purcell to anticipate by more than 70 years C. W. von Gluck's *Orfeo.* For if Gluck swept away the artificialities that had been grafted on Italian opera ever since Purcell's youth and earlier, Purcell simply ignored them and allowed his own common sense and imagination to guide him toward the shaping in *Dido and Aeneas* of what *Orfeo* is usually called—the first "reform opera." (Indeed, one might call it the first music drama, as distinct from opera in the conventional sense.) But this was his only chance, and his isolated, insular position conspired with his early death, the absence of any sufficiently strong successor and any system of patronage in damming up what might have grown into an operatic main stream in Britain. For Purcell, while as independently enterprising as Gluck, was technically a far more accomplished master.

Scarlatti, too, was a master of the first order. However, he did nothing to alter the Italian operatic conventions which by his time had become too rigid to be easily upset; he simply did first-rate work within their limitations. Among these was an exclusively Italian phenomenon, which however found its way until well into the middle of the 18th century into opera elsewhere—that of the male soprano and contralto. The barbarism of turning boys into eunuchs before their voices broke began in the church, where women singers were not allowed. Artificial treble voices were thus available which it became the fashion to admire in opera, the more so because these freak singers were capable of performing incredibly difficult florid passages, not only written for them by the composers, but also improvised by them in long cadenzas as elaborate as those inserted later into instrumental concertos. The absurdity of seeing eunuchs with soprano voices interpreting Greek gods and heroes, and sometimes taking women's parts, was accepted as one of the ordinances of opera.

Scarlatti's numerous and splendid operas are among the chief exemplars of this phase of excessive artifice, which causes them to survive all too precariously as historical curiosities. It has also robbed other composers of this period of any but the slenderest chance of survival, however fine the music of such men as A. Caldara, L. Vinci, L. Leo, J. A. Hasse, N. A. Porpora and G. B. Bononcini may have been. R. Keiser is also an offshoot of this school; he brought the Hamburg opera to its culmination with works of the Scarlatti type in a mixture of German and Italian words set to wholly Italianate music. J. Mattheson was associated with him; and so was the youthful Handel, who thus knew the Italian style of the day before his visit to Italy and his settling in England. Handel's first operas were like Keiser's and appeared at Hamburg. Those produced by him in London (35 works between 1711 and 1741) are all full of glorious music, but music almost entirely confined to arias, cruelly difficult to sing and such a dead weight on the plots that the whole of his operatic output is now an all but complete loss to the stage. Handel's operas are far less dramatic than his oratorios.

18th-Century Developments.—The greatest 18th-century librettist was Metastasio. It was chiefly he who influenced composers for a long time to come to persist in this overformalized kind of opera, which he handled with consummate skill. Between 1724 and 1771 most of the important opera composers, and many unimportant ones, in Italy and abroad, set Metastasio's texts, many of which were used over and over again. He caused much fine music to be written and opera as an art form to become stuck in a rut. But this happened only to the so-called *opera seria,* and another species—the *opera buffa*—now began to emerge in Italy and to revitalize the musical stage with characters more directly in touch with the audiences than the gods and heroes of antiquity, though even they at first appeared in the conventional guise of the harlequinade figures of the *commedia dell'arte.* The first Italian

comic operas were not independent works, but interludes inserted, scene by scene, between the acts of the serious operas to enliven the evening. These *intermezzi* were very slight, and only one has survived—*La serva padrona* by G. B. Pergolesi, produced in 1733.

It was this work which in 1752 brought the *opera buffa* to Paris as a model for the coming French comic opera; it was this, too, which unleashed the quarrel known as the *guerre des bouffons.* This lasted until 1754 and was nothing more than an argument, for argument's sake, between the partisans for Italian and for French opera, a dispute between men of letters rather than musicians.

The next great figure in French serious opera after Lully was J. P. Rameau. He did not follow the Metastasian conventions, but had rigid theories of his own and was musically somewhat cold and dry. But his works are as nobly classical in their way as the tragedies of Corneille and Racine, and bigger, though of lower vitality, than the French type of comic opera which developed in the hands of small-scale but delightful composers like A. Dauvergne, F. A. Philidor, P. A. Monsigny and, a little later, A. E. M. Grétry and N. Dalayrac. Their pieces were often tearfully sentimental but also freshly and charmingly human. Out of them developed the quite peculiar type of *opéra-comique,* which is not necessarily comic, but has to contain spoken dialogue. As late a work as G. Bizet's *Carmen,* with its original dialogue, is still an *opéra-comique,* for all its tragic ending, and so were the "rescue operas" of the Revolution period, one of which, P. Gaveaux's *Léonore,* led by way of a close translation of its libretto straight to Beethoven's *Fidelio,* which is thus also in a sense an *opéra-comique.* In Italy the *opera buffa* continued well, and one of its major composers, B. Galuppi, had the advantage of finding a playwright of genius, C. Goldoni, for his librettist.

In Germany opera in the vernacular at last began to emerge in the middle of the 18th century. It did so as modestly as English so-called opera, which had started with the most famous of the ballad operas, *The Beggar's Opera* of 1728, and was to continue for a long time with slight pieces by T. Arne, S. Arnold, C. Dibdin, W. Shield and others. Indeed, the first impulse came to Germany from England: a translation of C. Coffey's ballad opera *The Devil to Pay,* with music by J. C. Standfuss, given at Leipzig in 1752, began the vogue of the *Singspiel,* a simply sentimental and even more naïvely humorous play with music restricted mainly to songs and choruses of an easy, popular kind. The first full-scale German opera, Mozart's *Die Entführung,* was still 30 years off, and even this retained some elements of the "song-play."

With Gluck began the period which still supplies the regular repertory of today, although in recent times a few isolated works of earlier date have been added. But Gluck himself was slow to produce anything capable of surviving a first production, as indeed operas up to nearly the end of the 18th century were never intended to do. His numerous Italian operas, not all of them written before *Orfeo,* are in fact technically weaker than those by the best of his contemporaries, such as D. Terradellas, N. Jommelli and T. Traetta. There is more vitality in his French comic operas, written for the Viennese court, but they are little more than plays with songs. For German opera he did nothing; indeed, like Handel, he set next to no German words to music.

Gluck's first "reform opera," *Orfeo ed Euridice,* appeared in Vienna in 1762 and *Alceste* followed in 1767. French versions of both (1774 and 1776), together with his four original French serious operas (1774–79), spread his influence to Paris, though he was himself influenced by Rameau to some extent, and they provoked another literary dispute there among his partisans and those of N. Piccinni, an Italian who wrote as nobly as Jommelli, but remained conservative. He and Gluck respected each other and took no part in the quarrel. Gluck's reforms—which did away with vocal virtuosity shown off for its own sake, suited the character of the music to the situation and turned stock figures into human beings—were really due in the first place as much to R. Calzabigi, the librettist of *Orfeo;* but that the composer knew very well what he was doing is evident from his preface to *Alceste.* Gluck still had to concede artificially happy endings, however, and in the works specially written for Paris he was obliged to retain the traditional ballet, which remained a feature of French *grand opéra.*

The 19th Century.—When we reach what may be called the modern repertory, it is possible to survey the rest of operatic history much more briefly, both because its major works are still familiar, or at least accessible, and because discussions of the principles underlying them (*e.g.,* Wagner's) may be found in many of the articles on individual composers.

The entry of Mozart into German opera with *Die Entführung aus dem Serail* has already been mentioned, and in his last year he was to climb to the topmost peak of the *Singspiel* with *Die Zauberflöte* (1791), which still belongs to that category, exalted and for the most part solemn and uplifting though it be. But he had already written several Italian works and produced his first masterpiece in that class, *Idomeneo,* in 1781. The three greatest, which indeed place him with Wagner and Verdi in the triumvirate of opera composers who have so far remained unmatched are *Le Nozze di Figaro* (1786), *Don Giovanni* (1787) and *Così fan tutte* (1790). In some ways Mozart stands alone in supreme mastery. Never has opera achieved such ideal balance between the conflicting elements that go to the making of it. In him alone music in itself of the purest shape and quality, the most flawless workmanship, is reconciled with all the dramatic claims made by a libretto: perfect delineation of characters, faultless timing of every situation, simultaneous handling of conflicting emotions in unified concerted pieces.

Some minor Germans continued to set Italian words; others tried their own language. But the first great opera in German was Beethoven's *Fidelio* (1805, revised 1806, 1814), though, as we have seen, its model was French and the musical influences behind it were Franco-Italian (M. L. Cherubini, F. Paer, E. Méhul). As an opera it is not perfect, and the spoken dialogue lowers its temperature; but its high moral tone is divested of smugness or ingenuousness by the incomparable elevation of the composer's musical thinking and feeling. *Fidelio* had no influence on later German works: its form was unsatisfactory and its music unapproachable.

The progress of German opera was threatened at the outset by the enormous success of G. A. Rossini, whose career began as early as 1810. His new type of *opera buffa,* with its enticing, peppery music, was made as welcome in Vienna and Germany as anywhere and interfered with the operatic careers of Germanic composers, making Schubert's impossible and C. M. Weber's difficult, and driving G. Meyerbeer first to Italy and then to Paris. Still, in 1821 Weber managed to bring out *Der Freischütz* in Berlin, and here for the first time was a musically important work thoroughly German in every respect, so much so indeed that it has never taken a firm footing anywhere else. It was also the first romantic opera of any consequence.

Romanticism, by this time established in literature, poured into opera after Weber's lurid story of the magic bullet. He also dealt with a French subject in *Euryanthe* (1823) and actually set an English libretto in *Oberon* (London, 1826). In Germany, though, a strongly romantic vein had already been apparent by 1816 in E. T. A. Hoffmann's *Undine,* a musically rather feeble work by a man whose major gift was literary, and to a lesser extent in Ludwig Spohr's *Faust.* In France romanticism took a rather different, semihistorical form in D. F. E. Auber's *La Muette de Portici,* a revolutionary opera (1828), and in Meyerbeer's works, especially *Robert le diable* (1831). Even in Italy, which was far less open to it, a streak of it is perceptible in works based on Sir Walter Scott: Rossini's *La Donna del lago* (1819) and G. Donizetti's *Lucia di Lammermoor* (1835). But both Rossini and Donizetti were at their best in *opera buffa,* which indeed, with the exception of the suavely lyrical works by the short-lived V. Bellini, remained the most vital operatic phenomenon in Italy until the advent of Verdi, who furnished only two examples of it, a failure in 1840 and *Falstaff* (1893), which, written when the composer was 80, is his most perfect work, flawless in every particular and even, unlike the operas of his earlier years, incomparably refined. It improves immeasureably on conventional *opera buffa* by removing its heartlessness and by adding poetry.

Verdi up to *Otello* (1887), and even there once or twice, could be crude; but from the first he never failed to be strikingly effective, and at his best he had not only an unfailing sense of the stage, but also a discriminating and resourceful musicianship far exceeding that of any of his Italian, and most of his other, contemporaries, and much more mastery in technical matters than is generally acknowledged. He was matched in skill only by Wagner, his exact contemporary, who, however, matured later. Wagner's *Rienzi* (1842) still shows the influence of G. L. P. Spontini, H. A. Marschner and Meyerbeer, whose works he knew well as a conductor. Wagner also knew what to his mind was feeble, artificial and illogical in conventional opera and by much theorizing arrived gradually at a thoroughgoing reform. Though this reform has not proved as vital in the hands of his imitators as he doubtless hoped, much less found general acceptance among later composers, it was more than suited to his own needs. What ultimately saved his work for future generations was not his feat of turning opera into music drama so much as his surpassing eminence as a composer. His resources are endless and perfectly serve his special requirements; his use of the leitmotiv (*q.v.*) is wonderfully eloquent and flexible,

not only because it does so much to allow the orchestra to express what the characters on the stage are doing and even thinking, but also because his handling of these themes developed into the very highest art of symphonic composition.

Romanticism in German opera verged on hysterical extravagance in Marschner's *Der Vampyr* (1828) and *Hans Heiling* (1833). Marschner also wrote an opera based on Scott's *Ivanhoe, Der Templer und die Judin* (1829). Another *Undine,* by G. A. Lortzing (1845), still enjoys some favour in Germany; but Lortzing's talent was particularly suited to comic opera, pieces deriving from the *Singspiel* and influenced by French works of the lighter kind, which flowered charmingly in Paris during the first half of the century under D. F. E. Auber, F. A. Boieldieu, A. C. Adam and L. J F Hérold.

In Russia, which now came on the operatic scene with M. I. Glinka, opera took a rather different turn, its subjects being as a rule either historical or fairy tale material. Glinka's two operas represent both tendencies: *A Life for the Tsar* (1836) the historical, *Russlan and Ludmilla* (1842) the fairy tale. Subsequent historical works were M. Mussorgsky's *Boris Godunov* (1874), A. Borodin's *Prince Igor* (posthumously, 1890) and N. Rimsky-Korsakov's *Ivan the Terrible* (1873). Most of Rimsky-Korsakov's works were fairy tales. Glinka is the great originator of many devices used by later Russians, Mussorgsky the undisciplined but powerful realist. All these were nationalist composers, but Tchaikovsky was more cosmopolitan. Except for *Eugen Onegin* (1879), however, he was never quite happy in his choice of subjects, his inspiration was unequal and his dramatic sense weak; but his technical competence and lyrical charm are considerable.

England for long had nothing of lasting value to contribute in the 19th century but M. Balfe scored successes in Italy, France and Russia as well as at home. During the last decades C. Stanford wrote fine, if not very stageworthy, works and Sir Arthur Sullivan's light pieces have remained unique of their kind, with a musical craftsmanship far surpassing that shown in the operettas of Jacques Offenbach and Johann Strauss. There were beginnings of national opera in Bohemia with F. Smetana, in Hungary with F. Erkel, in Poland with S. Moniuszko and in Spain with F. A. Barbieri.

Perhaps the most characteristic product of the 19th century, though by no means the most valuable, was the French *grand opéra,* in which C. F. Gounod, J. E. F. Massenet, among others, followed Meyerbeer and to which Rossini's last opera, *Guillaume Tell* (Paris, 1829), also belongs. It suffered from a heavy load of absurd traditions, such as the obligatory five acts and ballet. Bizet's work, culminating in the daringly inventive, realistic and splendidly orchestrated *Carmen* (Paris, 1875), blew refreshing air into this conventional stuffiness, as did, in another way, the profoundly original operas by H. Berlioz, which unfortunately had no success. A. Bruneau at the end of the century followed Bizet in a sense and V. d'Indy followed Berlioz, with a difference, but with much the same lack of success. In Italy the school of *verismo* began at that time. A. Ponchielli, R. Leoncavallo, P. Mascagni and U. Giordano turned out crudely effective works which appealed to the masses. G. Puccini followed the same lines, with better musicianship and a rather more refined artistic conscience. His *Tosca,* and G. Charpentier's *Louise,* a French work following some of the tendencies of *verismo,* both produced in 1900, brought the century to a close with both a threat and a promise.

The 20th Century.—In the next two years appeared two new composers who seemed to sweep all this away. Richard Strauss's *Feuersnot* (1901) was still Wagnerian in its music, but attempted to scandalize the public by a modern and "immoral" libretto. Claude Debussy's *Pelléas et Mélisande* (1902) first of all made a new departure by using a spoken play by Maeterlinck instead of a specially written libretto, and it shocked its hearers as much as Strauss's work had done, though in quite a different way, by disappointing every expectation of accustomed procedures. It was uneventful, unemphatic, undervitalized and almost devoid of action. But those who looked for musical quality of the finest kind and were not to be put off by understatement and drastic harmonic innovations learned to cherish this ultra-refined work, which remained unique, for Debussy never wrote another opera. Strauss did, and continued until long into old age, retaining his mastery to the last, but falling back too often on what had served him well before. Even at his best he is uncertain in style and taste, but astonishingly inventive and vibrant. *Der Rosenkavalier* (1911) is his most glamorous success, *Ariadne auf Naxos* (1912) his most enchanting work, but just beginning to show the first cracks of decay.

E. F. C. d'Albert's *Tiefland* (1903), F. Schreker's various works, which approach decadence, R. Zandonai, I. Montemezzi and E. Wolf-Ferrari (in *I Gioielli della Madonna*) continued along the line of *verismo*. Wolf-Ferrari also revived the Goldonian comedy of the 18th century, with a charm that seemed faded and a humour more Germanic than Italian. High comedy of the most sophisticated kind is represented by M. Ravel's brilliant *L'Heure espagnole* (1911). F. B. Busoni's operas ran along a remote sideline in the 20th century much as Berlioz's had done in the 19th.

One of the most interesting figures of the 20th century is the Czech L. Janáček, as thorough a nationalist as Mussorgsky and one of the most original minds in all opera, untouched by any fashion and free from preconceived theories except those connected with the natural declamation of words which unfortunately make his work almost untranslatable. The notion that theory must come first and practice conform to it, on the other hand, makes A. Schönberg's short essays in opera inaccessible to those who wish to see what an opera looks like on the stage rather than in the score. It must be said, though, that Schönberg did not apply his 12-note system rigidly to his dramatic works. A. Berg in his remarkable *Wozzeck* (1925) and his unfinished *Lulu* (posthumously, 1937) used it only as far as it would bend to his intentions. What is more remarkable about his works is that they are cast in various traditional musical forms scene by scene without allowing the least constraint to appear in the dramatic events, if also, it has to be admitted, without making these forms perceptible to the listener. An *a priori* theorist of another sort is I. Stravinsky, who always makes up his mind precisely beforehand as to what he is to do and then does it in cold blood, with extraordinary precision and skill. His Hogarthian opera, *The Rake's Progress* (Venice, 1951), which has actually very little to do with Hogarth, is deliberate 18th-century pastiche, refined, witty, often charming, but dry and appealing to intellect and taste alone.

In Germany H. Pfitzner, after several neoromantic works, produced a masterpiece of a kind in *Palestrina* (1917), long and heavy-handed, old-fashioned in some ways, but impressive. P. Hindemith's *Mathis der Maler* (Zürich, 1938) is something of the same sort, masterly, noble and inclined to dullness, but more up-to-date in its idiom. In Italy I. Pizzetti has written severely classicist works, rather like a latter-day Cherubini, and G. F. Malipiero has renewed styles and traditions of the past, not unlike Stravinsky, but exclusively Italian and with more warmth.

To modern English opera Ralph Vaughan Williams has contributed a good deal, notably his setting of J. M. Synge's *Riders to the Sea* (1938), a concentrated and profoundly truthful tragic masterpiece in one act. With Benjamin Britten's *Peter Grimes* (1945), English opera conquered the cosmopolitan scene far more quickly than Purcell did and with much greater justification than Balfe. None of his later stage works made the same impression abroad, but they made opera once again seem worthy of the attention of British composers of genius. By 1954 others had written or were writing full-scale works for the stage, including A. Benjamin, Lennox Berkeley, Sir Arthur Bliss, A. Bush, M. Tippett and Sir William Walton.

In the middle of the century operatic output in the United States brought forward work either actually or potentially capable of being exported with success. G. Gershwin's only opera, *Porgy and Bess* (1935) was perhaps helped to widespread European appreciation by the previous vogue of his musical comedies and jazz pieces. Among other composers whose operas travelled abroad or seemed likely to do so in 1953 were G. C. Menotti, M. Blitzstein and V. Thomson.

Dent (New York, London, 1931).

(E. W. Bm.)

OPHICLEIDE, a brass wind instrument with a cup-shaped mouthpiece and keys; in fact the bass of the now obsolete family of keyed bugles. The name (from Gr. ὄφις serpent, and κλεῖδες keys), applied to it by Jean Hilaire Asté, known as Halary, the patentee of the instrument, is hardly a happy one, for there is nothing of the serpent about it. The ophicleide is almost perfect theoretically, for it combines the natural harmonic scale of the brass wind instruments having cup-shaped mouthpieces, such as the trumpet, with a system of keys, 9 to 11 in number (a 12th added in 1822 never came into general use), producing a full chromatic scale, and it is capable of absolutely accurate intonation. Unfortunately its tone is not satisfactory, the lower register being rough, the medium coarse and the upper wild and unmusical; but for some special effects it served well (*e.g.,* the donkey's bray in Mendelssohn's *Midsummer Night's Dream* overture). It has been orchestrally superseded by the bass tuba and by the double bassoon and, in the military band, by the bombardon.

The invention of the ophicleide is sometimes falsely attributed to Alexandre Frichot, a professor of music at Lisieux. Actually the first idea of adding keys to instruments with cupped mouthpieces, unprovided with lateral holes, with the aim of filling up some of the gaps between the notes of the harmonic scale, goes back, according to E. L. Gerber, to Kölbel, a horn player in the St. Petersburg Imperial orchestra, about 1760. Anton Weidinger, trumpeter in the Austrian imperial band, improved upon this first attempt, and applied it in 1800 to the trumpet. In 1810 Joseph Halliday, bandmaster of the Cavan militia, patented a key bugle: a copy of it was ordered in Paris from Halary, a professor of music and instrument maker, who brought out in 1817 and patented in 1821 a set of three key bugles, the bass instrument of which he named *ophicléide,* with the misleading alternative *ou serpent à clef*. The instrument was never standardized, and the lack of a system of fingering helped to bring about its extinction.

OPHIR, an unidentified region famous in Old Testament times for its fine gold. Solomon's Tyrian sailors brought its gold for that monarch. The geographical list of Genesis X. associates it with Sheba and Havilah, the latter also being a recognized gold bearing region (Gen. ii. 11). Solomon's ships set forth from Ezion-Geber at the head of the Gulf of Akaba. Presumably then it lay somewhat to the south of Suez, but where?

(1) *East Africa.*—The extensive and imposing ruins discovered at Zimbabwe in Mashonaland, about 200m. inland from Sofala, have been acclaimed as marking the site of long lost Ophir. But careful investigation has resulted in depriving the ruins of any claim to great antiquity. An identification with Zanzibar has been suggested.

(2) *The Far East.*—The fact that three years were occupied in the voyage to Ophir (1 Ki. x. 22) as well as the nature of the cargoes (gold, silver, ivory, apes and peacocks) suggests a distant voyage, although attempts have been made to minimize these arguments. The Indus delta; Johore; Supara in Goa; Farther India; Malabar; Malacca; Sumatra have all been adduced.

(3) *Abyssinia.*—The territory on the Abyssinian coast from ancient Adulis to Bab-el-Mandeb whose inhabitants call themselves Aphar.

(4) *Arabia.*—The most common and, indeed, the most plausible view is that Ophir was somewhere in Arabia. It has been sought in West Arabia at Asyr between the Hejāz and Yemen; but the view that it is some district on the southern coast appears the most atractive.

The lack of sufficient data for identification has given and no doubt will continue to give scope for imagination. There have not been wanting wild and fanciful surmisings. Spain, Armenia, Phrygia and even Peru have had their advocates. (E. Ro.)

OPHITES. Strictly speaking, this is the name given to an obscure sect of Gnostics, of which our knowledge is derived mainly from Origen (*Contra Celsum,* vi. 25) supplemented by Irenaeus (*Adv. Haer.,* i. 30) and Epiphanius (*Haer.,* xxxviii); but the more important use of the term is as the comprehensive name for a group of Gnostic sects which resemble one another, first, because no name of any personal founder or leading teacher is associated with any of them; and further, because they attach religious importance to the serpent. The type of mythology may be illustrated from the account of Irenaeus. It begins with a triad, the highest deity, described as "primal Man"; intellect or reason, his Son, the "second Man"; and the Spirit, introduced as a female principle. Through her the Christ is begotten as "third Man." Christ ascended, with the Spirit, but in their ascent a ray of light fell on the waters. This was Sophia (prudence or wisdom) and from this contact came Ialdabaoth the "demiurge." He in turn produced six powers, and (from the dregs of matter) the serpent. Ialdabaoth then announced himself as the supreme Being; and when man (created by the six powers) gave thanks not to Ialdabaoth but to the primal Man, the former created a woman (Eve) to destroy him. Then Sophia sent the serpent (as benefactor) to persuade Adam and Eve to eat of the tree of knowledge and so break the commandment of Ialdabaoth, who banished them from paradise to earth. After a long war between mankind, aided by Sophia, and Ialdabaoth (this is the inner meaning of the Old Testament story), the Spirit sent the Christ to earth to enter the pure vessel, the virgin-born Jesus. Jesus Christ worked miracles and declared himself the Son of the primal Man. Ialdabaoth instigated the Jews to kill him, but only Jesus died on the cross, for Christ had departed from him. Christ then raised the spiritual body of Jesus, which remained on earth for 18 months, initiating a small circle of elect disciples.

This form of Ophitism is Christianized to a larger extent than others of the kindred sects, in most of which the Christian element is slighter and less essential. They are also far less impregnated with Greek philosophy than the "classic systems of Gnosticism"; and the early sources warrant the inference that the mythology itself is only a covering for observances (ritual, initiation, secret pass-words, incantations) characteristic of mystery-religions.

Notwithstanding the conclusion based by De Faye on his instructive investigations, the prevalent view holds the field, namely, that Ophitism represents a primitive phase of Gnosticism, which was gradually developed and transformed into various great speculative systems by a series of historic teachers.

See E. F. Scott, art. "Ophitism" in Hastings, *Encyclopaedia of Religion and Ethics;* Lichtenhahn, art. "Ophiten" in Herzog-Hauck, *Realencyklopädie;* E. de Faye, *Gnostiques et Gnosticisme* (1913); Reitzenstein, *Peimandres* (1904). *See* also GNOSTICISM. (S. H. M.)

OPHIUCHUS, in astronomy, a constellation of the northern hemisphere, anciently named Aesculapius, and mentioned by Eudoxus (4th century B.C.) and Aratus (3rd century B.C.). According to the Greek fables, it variously represents: Carnabon (or Charnabon), king of the Getae, killing one of the dragons of Triptolemus, or Heracles killing the serpent at the river Sangarius (or Sagaris), or the physician Asclepius (Aesculapius), to denote his skill in curing snake bites. Like Sagittarius (which it adjoins) it includes a region of the sky rich in globular clusters and diffuse nebulae. A very bright nova or new star was observed in Ophiuchus in 1604.

OPHIUROIDEA: *see* BRITTLE STARS.

OPHRYS, a genus of plants of the orchid family (*Orchidaceae*), comprising about 30 species native to Europe, western Asia and North Africa, including the bee-orchis (*O. apifera*), the spider-orchis (*O. aranifera*) and the fly-orchis (*O. muscifera*), the second of which is one of the few orchids that are self-fertilized.

(*See* ORCHIDS; also C. Darwin, *The Fertilisation of Orchids.*)

OPHTHALMOLOGY (*see* EYE, HUMAN). The science of ophthalmology deals with the processes by means of which the images of external objects are brought to our consciousness. It is therefore concerned with:

(*a*) the eye itself; (*b*) the nerve paths and tracts which convey visual impulses originating in the eye, through the different parts of the brain to the brain cortex, where these impulses are converted into conscious impressions; (*c*) the eyelids which cover and protect the eyes; (*d*) the tear glands and ducts; (*e*) the muscles that bring about the movements of the eyes and keep them trained in the desired direction; (*f*) the nerves and their complicated cerebral connections which supply these muscles; (*g*) the bony walls of the orbit; (*h*) the blood-vessels and lymph paths which maintain the nutrition of all these structures.

It treats of disease in these parts and derives importance from the fact that many diseases of the central nervous system and many general diseases manifest themselves by some derangement of function or structure which can be detected by the ophthalmic surgeon.

The eye is unique in the body in that its retina, which is available to minute examination by means of the ophthalmoscope, is the only portion of the brain available to inspection during life. Similarly, the arteries and veins which supply the retina can also be minutely examined during life, the diseases of them observed and followed in all their changes. The value of these observations is enhanced by the fact that the eye itself acts as a low-power microscope, providing a magnification of about 15 diameters for the examination of these structures. The eyes are the subject of a number of hereditary diseases, and form one of the most convenient media for the study of transmission of such diseases.

Affections of the Eye.—The function of the eyeball is to provide that a clear image of external objects shall be formed upon the retina, but in certain cases it departs from the normal and the acuity of sight is lowered. It may be too long, so that the retina lies behind the point at which the images of external objects are formed; this is myopia or short-sightedness, and may be compensated by the wearing of concave lenses in the form of spectacles. In other cases, the eyeball is too short and the retina lies in front of the point at which the image of external objects is formed. This is hypermetropia or long-sightedness; it can be compensated by the focusing muscle of the eye, making the lens more convex; or, preferably, by the wearing of appropriate convex lenses in the form of spectacles. In astigmatism the refractive power of the eye varies in different axes, so that, for instance, in an extreme case the vertical axis may be myopic whilst the horizontal axis is hypermetropic.

Normally the visual axes of the two eyes are parallel and images of external objects are formed upon corresponding points of each retina. This arrangement is largely responsible for stereoscopic vision, which enables us to judge the position of objects in space with accuracy. Should it be upset *e.g.* by paralysis of some of the muscles, stereoscopic vision is lost and double vision usually arises.

Eyeball and Camera Compared.—The eyeball may be likened to a photographic camera. Roughly speaking it is globular in shape and is an inch long in all dimensions. The front part, or cornea is curved, is perfectly transparent and functions as a lens. Behind it is a chamber filled by the aqueous humour—little more than water. Further back is the iris—the coloured part of the eye. The hole in its centre forms the pupil, and by contraction or dilation of the tissues of the iris the pupil can be varied in size through a wide range; it may be compared to the stop in the camera. In bright lights the pupil is small, and it becomes large in dull illumination. The iris rests behind upon the lens.

The lens is bi-convex, its back surface having the greater curvature. It is perfectly transparent, and the focusing of the eye for near or distant objects is brought about by alteration in its curvatures by contraction of the ciliary muscle. Here is an essential difference between the eye and the photographic camera, whose focus is adjusted by shifting the position of the lens. As age proceeds, opacities frequently develop in the lens; almost everyone at the age of 60 or over may be said to have the beginnings of cataract, though the sight is quite unaffected thereby. When, however, these opacities involve the centre of the lens, and render sight very imperfect, the term of cataract becomes applicable; in such a case the cataract can be removed by operation and the sight restored.

Vitreous Chamber and Retina.—Behind the lens is the vitreous chamber, which is occupied by a perfectly transparent, colourless substance, much like white of egg. Clothing the back of the eye, and extending forward some distance in front of its equator, is the retina. It rests upon a highly vascular membrane which is responsible for the nutrition of the greater part of it, namely the choroid; in man, however, the retina has its own blood vessels clearly visible with the ophthalmoscope. The retina may be likened to the sensitive plate of the camera for upon it images are formed which initiate impulses which, when conveyed to the cortex of the brain, give rise to the sensations of sight. Its sensitive layer is placed posteriorly, and is composed of delicate structures known as the rods and cones.

At the central spot or yellow spot of the retina, the point of distinct vision, cones alone are present. The rods are believed to be concerned with lights of lower intensities, and in accordance with this they alone are present in night-flying birds (*see* VISION or SIGHT).

Optic Nerves and the Cerebral Cortex.—The nerve fibres from the retina converge upon the optic disk, and leave the eye as the optic nerve, which traverses the orbit to enter the skull. Inside the skull the two optic nerves meet and each is divided into two parts, one part continuing to the mid-brain on the same side, the other part crossing over to the opposite side. This crossing forms the chiasma; in many animals, the birds for instance, the whole of each optic nerve crosses over in this way. Beyond the chiasma the nerve fibres are again collected into a compact bundle known as the optic tract, which terminates in the mid-brain. From here nervous impulses are relayed in two chief directions; some connect up with the nerves which control the movements of the eyes and others, forming the so-called optic radiations, make a long sweep backwards to reach the cerebral cortex, where, as already stated, the impulses are transformed to sensations of sight.

The exact area of the cerebral cortex, in which these fibres end, is known with great accuracy and forms the visual cortex. It is placed at the extreme hind end of the brain, and the adjoining mesial surface of each hemisphere, in the region of the calcarine fissure (*see* BRAIN). Should a minute portion of this cortex be cut out as the result of injury or blocking of its blood supply, the precise area of the defect which will be found in the vision can be stated with certainty. This accurate localisation was much advanced as a result of observations that were made during World War I.

General Diseases and the Eye.—Among the general diseases of the body in which important manifestations occur in connection with the eye a few may be mentioned.

In brain tumours or abscesses, swelling of the optic disk is seldom absent, and forms perhaps the most important sign in the diagnosis of the condition. In addition, the ocular nerves may have their functions interrupted, so that the movements of the eyes are interfered with, they no longer move in unison and double vision occurs. If nothing can be done for the brain tumour the optic nerve atrophies and blindness ensues. In advanced renal disease changes in the retina develop and convey a particularly grave prognosis, for patients seldom live as long as two years after their discovery.

In diabetes a similar change may also arise, which may greatly spoil the sight, and although of less serious import than in renal cases, it must be considered a bad omen. Venereal disease frequently attacks the eye, whether in the early or late stages, and is perhaps the most prolific source of blindness. Tuberculous disease occasionally occurs.

In diseases of the blood in general, eye signs are very common, and there are many other diseases where the diagnosis may be greatly assisted by the discovery of changes in some part of the ocular apparatus.

The introduction of the "slit lamp" has made possible many investigations which previously were quite outside the scope of an ophthalmologist. (R. F. M.)

OPIE, AMELIA (1769–1853), English author, daughter of James Alderson, a physician in Norwich, where she was born on Nov. 12, 1769. Miss Alderson had inherited radical principles and was an ardent admirer of Horne Tooke. She was intimate with the Kembles and with Mrs. Siddons, with Godwin and Mary Wollstonecraft. In 1798 she married John Opie, the painter. In 1801 she produced a novel entitled *Father and Daughter,* which showed genuine fancy and pathos. She published a volume of graceful verse in 1802; *Adeline Mowbray* followed in 1804, *Simple Tales* in 1806, *Temper* in 1812, *Tales of Real Life* in 1813, *Valentine's Eve* in 1816, *Tales of the Heart* in 1818, and *Madeline* in 1822. In 1825 she joined the Society of Friends. She died at Norwich on Dec. 2, 1853.

A *Life,* by Miss C. L. Brightwell, was published in 1854.

OPIE, JOHN (1761–1807), English historical and portrait painter, was born at St. Agnes near Truro in May 1761. While quite young he won some local reputation by portrait-painting; and in 1780 he started for London, under the patronage of Dr. Wolcot (Peter Pindar), and was introduced to the town as "The Cornish Wonder," a self-taught genius. He became a fashionable portrait painter, but after a period of prosperity fell into neglect. He then set himself to make good the defects of his early education by studying Latin, French and the English classics as well as the technique of his art.

His first important historical subject to be exhibited was the "Assassination of James I.," followed by his "Murder of Rizzio" which secured his immediate election, in 1786, as associate of the Academy, of which he became a full member in 1787. He was employed on five subjects for Boydell's "Shakespeare Gallery"; and until his death on April 9, 1807, his practice alternated between portraiture and historical work. His painting shows breadth of handling and a certain rude vigour, individuality and freshness, but lacks grace and poetic feeling.

Opie's portraits of Mary Wollstonecraft, of himself, and the "Portrait of a Boy" are in the national collections. He also wrote a *Life of Reynolds* in Wolcot's edition of Pilkington and a *Letter on the Cultivation of the Fine Arts in England,* in which he advocated the formation of a national gallery. His Academy *Lectures* were published in 1809 with a memoir by his widow (*see* above). *See* also Claude Phillips,

"John Opie" (*Gazette des Beaux-Arts,* 1892, i, 299).

OPISTHODOMOS: *see* EPINAOS.

OPITZ VON BOBERFELD, MARTIN (1597–1639), German poet, was born at Bunzlau, Silesia, on Dec. 23, 1597, and studied at Frankfurt-on-Oder, Heidelberg and Leyden. He led a wandering life in the service of various territorial nobles. In 1624 he was appointed councillor to duke George Rudolf of Liegnitz and Brieg in Silesia, and in 1625, as reward for a requiem poem composed on the death of archduke Charles of Austria, was crowned laureate by the emperor Ferdinand II who a few years later ennobled him under the title "von Boberfeld." He was elected a member of the *Fruchtbringende Gessellschaft* in 1629, and in 1630 went to Paris, where he made the acquaintance of Hugo Grotius. He settled in 1635 at Danzig, where Ladislaus IV of Poland made him his historiographer and secretary. Here he died of the plague on Aug. 20, 1639.

Opitz was the head of the so-called First Silesian school of poets, and was during his life regarded as the greatest German poet. He was the "father of German poetry," at least in respect of its form; his *Buch von der deutschen Poeterey,* written in 1624, put an end to the hybridism that had until then prevailed, and established rules for the "purity" of language, style, verse and rhyme. Opitz's own poems are in accordance with the rigorous rules which he laid down. They are mostly a formal and sober elaboration of carefully considered themes, and contain little beauty and less feeling. To this didactic and descriptive category belong his best poems.

Collected editions of Opitz's works appeared in 1625, 1629, 1637, 1641, 1690 and 1746. His *Ausgewählte Dichtungen* have been edited by J. Tittmann (1869) and by H. Oesterley (Kürschner's *Deutsche Nationalliteratur,* vol. xxvii. 1889). There are modern reprints of the *Buch von der deutschen Poeterey* by W. Braune (2nd ed., 1882), and, together with *Aristarchus,* by G. Witkowski (1888), and also of the *Teutsche Poemata,* of 1624, by G. Witkowski (1902). *See* H. Palm, *Beiträge zur Geschichte der deutschen Literatur des 16ten und 17ten Jahrhunderts* (1877); K. Borinski, *Die Poetik der Renaissance* (1886); R. Beckherrn, *Opitz, Ronsard und Heinsius* (1888). Bibliography by H. Oesterley in the *Zentralblatt für Bibliothekswesen* for 1885.

OPIUM. The drug known in commerce as opium is derived from the immature fruits of *Papaver somniferum* (fig. 1), family *Papaveraceae,* by slightly incising the fruits and collecting and drying the exuded milky juice.

There are several forms of the plant in cultivation for yielding opium. The truly wild plant (*var. setigerum*) is found on the northern coast of the Mediterranean. It has acutely toothed leaves, the lobes sharp-pointed, each ending in a bristle. The leaves, flower stalks and sepals are covered with scattered bristly hairs, and the stigmata are seven or eight in number.

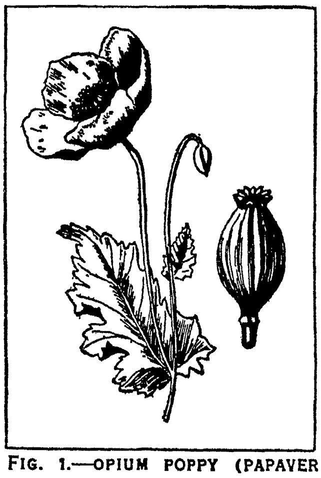

FIG. 1.—OPIUM POPPY (PAPAVER SOMNIFERUM)

The variety of the plant chiefly cultivated in Asia Minor and Egypt is distinguished by having a sub-globular fruit and 10 to 12 stigmata. It is glabrous and is known as *var. glabrum.*

The one cultivated in Persia is *var. album,* which has a fruit more or less egg-shaped; the pores below the stigmata do not open when the fruits are ripe. It varies in the colour and shape of the petals. Those (the majority) with white petals have usually white seeds, those with reddish or purple petals have usually slate-coloured seeds.

Cultivation.—The successful cultivation of the plant is only possible where there is not an excessive rainfall and where the climate is tropical or sub-tropical. The yield of opium is smaller in temperate than in tropical regions and the industry can only be profitably carried on where labour and land are sufficiently cheap and abundant.

The mode of cultivation adopted varies. In Turkey, from which the chief supplies of medicinal opium are obtained, the cultivation is carried on by peasant proprietors. A naturally light and rich soil is chosen, improved by manure and irrigation where necessary, and the land should be sloping and well drained, moisture in excess being injurious. The ground is ploughed twice, the second time crosswise. The seed is mixed with four times its weight of sand to prevent it being sown too thickly, $\frac{3}{4}$ to 1 lb.

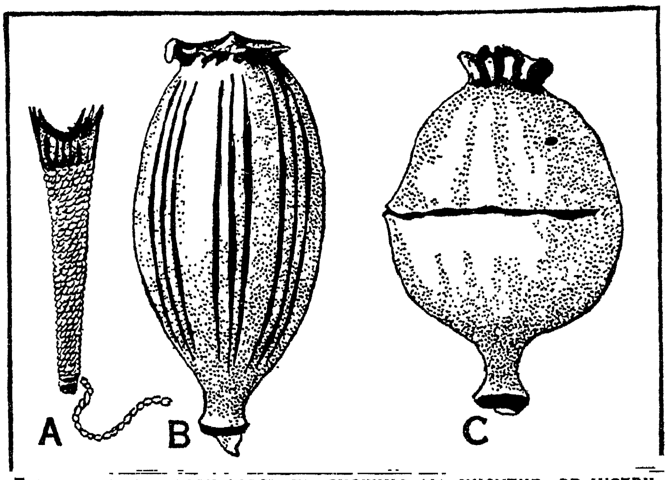

FIG. 2.—OPIUM POPPY CAPSULES, SHOWING (A) NUSHTUR, OR INSTRUMENT USED IN INDIA FOR MAKING THE INCISIONS, DRAWN FROM SPECIMENS IN THE MUSEUM OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, (B) CAPSULE AS INCISED IN INDIA, (C) MODE OF INCISION PRACTISED IN TURKEY

being used to every *toloom* (1,600 sq.yd.). The crop is very uncertain owing to droughts, ground-frosts and locusts. To avoid failure, and to allow time for collecting the produce, every toloom has three sowings from October to March, the crops thus coming to perfection in succession. In localities where there is hoar frost in spring, the seed is sown in September, or at latest in the beginning of October. The yield of opium and seed is then greater than if sown later. After sowing, the land is harrowed and young plants are hoed and weeded, chiefly by women and children, from early spring until the time of flowering. In the plains the flowers expand at the end of May, and on the uplands in July. At this period gentle showers are of great value, as they cause an increase in the subsequent yield of opium. The petals fall in a few hours, and the capsules grow so rapidly that in a short time—generally from nine to 15 days—the opium is fit for collection. This period is known by the capsules yielding to pressure from the fingers, by assuming a lighter green tint, and by exhibiting a kind of bloom called "cougak," easily rubbed off with the fingers; they are then about $1\frac{1}{2}$ in. in diameter. The incisions are made by holding the capsule in the left hand and drawing a knife two-thirds round it, or spirally beyond the starting point (fig. 2), great care being taken not to let the incisions penetrate to the interior, lest the juice should flow inside and be lost; in this case also it is said that the seeds will not ripen, and that no oil can be obtained from them. The operation is usually performed after the heat of the day, commencing early in the afternoon and continuing to nightfall, the exuded juice being collected next morning. This is done by scraping the capsule with a knife, transferring the concreted juice to a poppy-leaf held in the left hand, the edges of the leaf being turned up to avoid spilling the juice; the knife-blade is moistened with saliva by drawing through the mouth after every alternate scraping to prevent the juice from adhering to it. When as much opium has been collected as the size of the leaf will allow, another leaf or more is wrapped over the top of the lump, which is then placed in the shade to dry for several days. The pieces vary in size from about 2 oz. to 2 lb., being made larger in some districts than in others. The capsules are generally incised only once, but the fields are visited a second or even a third time to collect the opium from the poppy-heads subsequently developed by the branching of the stem. The yield of opium varies, even on the

same piece of land, from one-third to $7\frac{1}{2}$ *chequis* (or 1·62 lb.) per *toloom*, the average being $1\frac{1}{2}$ *chequis* of opium and 4 bushels (50 lb.) of seed. The seed, which yields 35 to 42% of oil, is worth about two-thirds the value of the opium. The whole of the operation must, of course, be completed in the few days, usually from five to ten, during which the capsules are capable of yielding the drug.

Macedonian Opium.—Four varieties of poppy are cultivated—two with white flowers and large oval capsules without holes under their "combs" (stigmata), and bearing respectively yellowish and white seed, and the other two having red or purple flowers and seeds of a slate colour with a reddish layer under the surface, one bearing small capsules perforated just below the top and the other larger capsules not perforated. The white varieties are recommended as bearing more abundant opium of superior quality. The yellow seed is said to yield the best oil; that obtained by hot pressure is used for lamps and for paint and the cold-pressed oil for culinary purposes.

Indian Opium.—The poppy grown in India is usually the white-flowered variety, but in the Himalayas a red-flowered poppy with dark seeds is cultivated. The land intended for poppy culture is usually near villages, in order that it may be more easily manured and irrigated. On a rich soil a crop of maize or vegetables is grown during the rainy season, and after its removal in September the ground is prepared for poppies. Under less favourable circumstances the land is prepared from July till October by ploughing, weeding and manuring. The seed is sown between Nov. 1 and 15, and germinates in 10 or 15 days. The fields are divided for purposes of irrigation into beds about 10 ft. square, which usually are irrigated between November and February; but if the season be cold, with hardly any rain, the operation is repeated five or six times. When the seedlings are 2 or 3 in. high, they are thinned out and weeded. The plants during growth are liable to injury by severe frost, excessive rain, insects, fungi and the growth of a root-parasite (*Orobanche indica*). The poppy flowers about the middle of February, and the petals, when about to fall, are collected for the purpose of making "leaves" for the spherical coverings of the balls of provision opium, or cannon ball opium as it is popularly called.

Persian Opium.—The variety grown in Persia appears to be *var. album*, having roundish ovate capsules. Several forms of this variety are grown. The best quality of Persian opium is said to be derived from the white-flowered form, which is the earliest to flower and most widely grown; a second quality from a bizarre flower with deeply cut petals and a central band of bluish-purple flanked with rich magenta; a third quality from a white flower with broad margins and an apex of salmon pink and magenta; a fourth from a dark scarlet flower with a central band of bluish purple to within a fifth of the apex of the petals; a fifth from a dark bluish purple flower; a sixth from a lilac flower suffused with faint purple colour, which is considered to yield a very poor quality indeed. The more fully exposed the plants are to the sun the finer the crop.

European Opium.—Experiments made in England, France, Italy, Switzerland, Greece, Spain, Germany, and even in Sweden prove that opium as rich in morphia as that of Eastern countries can be produced in Europe. In 1830, Young, a surgeon at Edinburgh, succeeded in obtaining 56 lb. of opium from an acre of poppies, and sold it at 36s. a pound. In France, the cultivation has been carried on since 1844 at Clermont-Ferrand by Aubergier. The juice, of which a workman is able to collect about 9·64 troy oz. in a day, is evaporated by artificial heat immediately after collection. The juice yields about one-fourth of its weight of opium, and the percentage of morphia varies according to the variety of poppy used, the purple one giving the best results. By mixing assayed samples he is able to produce an opium containing uniformly 10% of morphia. It is made up in cakes of 50 grammes but is not produced in sufficient quantity to become an article of wholesale commerce. Some specimens of French opium have been found by Guibourt to yield 22·8% of morphia, being the highest percentage observed as yet in any opium Experiments made in Germany by Karsten, Jobst, and Vulpius have shown that it is possible to obtain in that country opium of excellent quality, containing 8 to 13% of morphia. It was found that the method yielding the best results was to make incisions in the poppy-heads soon after sunrise, to collect the juice with the finger immediately after incision, and evaporate it as speedily as possible, the colour of the opium being lighter and the percentage of morphia greater than when the juice was allowed to dry on the plant. Cutting through the poppy-heads caused the shrivelling up of the young fruit, but the heads which had been carefully incised yielded more seed than those which had not been cut at all. Newly manured soil was found to act prejudicially on the poppy. The giant variety of poppy yielded most morphia.

Medicine.—Of the opium alkaloids only morphine and codeine are used to any extent in medicine. Thebaine is not so used, but is an important and sometimes very dangerous constituent of the various opium preparations, which are still largely employed, despite the complexity and inconstant composition of the drug. Of the other alkaloids narceine is hypnotic, whilst thebaine, papaverine and narcotine have an action which resembles that of strychnine. So complex a drug as opium is necessarily incompatible with a large number of substances. Tannic acid, for instance, precipitates codeine as a tannate, salts of many of the heavy metals form precipitates of meconates and sulphates, whilst the various alkalis, alkaline carbonates and ammonia precipitate the important alkaloids.

The pharmacology of opium differs from that of morphine (*q.v.*) in a few particulars. The chief difference is due to the presence in opium of thebaine, which readily affects the more irritable spinal cord of very young children. In infants especially opium acts markedly upon the spinal cord, and, just as strychnine is dangerous when given to young children, so opium, because of the strychnine-like alkaloid it contains, should never be administered, under any circumstances or in any dose, to children under one year of age.

When given by the mouth, opium has a somewhat different action from that of morphine. It often relieves hunger, by arresting the secretion of gastric juice and the movements of the stomach and bowel, and it frequently upsets digestion from the same cause. Often it relieves vomiting, though in a few persons it may cause vomiting, but in far less degree than apomorphine, which is a powerful emetic. Opium has a more marked diaphoretic action than morphine, and is much less certain as a hypnotic and analgesic.

Toxicology. (*See* also DRUG ADDICTION and POISON).—Under this heading must be considered acute poisoning by opium, and the chronic poisoning seen in those who eat or smoke the drug. Chronic opium poisoning by the taking of laudanum—as in the familiar case of De Quincey—need not be considered here, as the hypodermic injection of morphine has almost entirely supplanted it.

The acute poisoning presents symptoms not easily distinguished from those produced by alcohol, by cerebral haemorrhage and by several other morbid conditions. The differential diagnosis is of the highest importance, but very frequently time alone will furnish a sufficient criterion. The patient who has swallowed a toxic or lethal dose of laudanum, for instance, usually passes at once into the narcotic state, without any prior excitement. Intense drowsiness yields to sleep and coma which ends in death from failure of the respiration. This last is the cardinal fact in determining treatment. The comatose patient has a cold and clammy skin, livid lips and ear-tips—a grave sign—and "pin-point pupils." The heart's action is feeble, the pulse being small, irregular and

often abnormally slow. The action on the circulation is largely secondary, however, to the all-important action of opium on the respiratory centre in the medulla oblongata. The centre is directly poisoned by the circulation through it of opium-containing blood, and the patient's breathing becomes progressively slower, shallower and more irregular until finally it ceases altogether.

Treatment.—In treating acute opium poisoning the first proceeding is to empty the stomach. The best emetic is apomorphine, which may be injected subcutaneously in a dose of about one-tenth of a grain. But the gastric wall is often paralyzed in opium poisoning, so that no emetic can act. It is therefore better to wash out the stomach, at half-hour intervals, with a solution containing about ten grains of salt to each ounce of water. If apomorphine is obtainable, both of these measures may be employed. Potassium permanganate decomposes morphine by oxidation, the action being facilitated by the addition of a small quantity of mineral acid to the solution. The physiological as well as the chemical antidotes must be employed. The chief of these are coffee or caffeine and atropine. A pint of hot strong coffee may be introduced into the rectum, and caffeine in large doses—10 or 20 grains of the citrate—may be given by the mouth. A 20th, even a 10th of a grain of atropine sulphate should be injected subcutaneously, the drug being a direct stimulant of the respiratory centre. Every means must be taken to keep the patient awake. He must be walked about, have smelling salts constantly applied to the nose, or be stimulated by the faradic battery. But the final resort in cases of opium poisoning is artificial respiration, which should be persevered with as long as the heart continues to beat.

OPIUM EATING AND OPIUM SMOKING. It is evident that the ancient Egyptians had no knowledge of the medicinal and other properties of opium, as there is no reference to it in their literature. Opium was taken to Greece, and Homer (9th century B.C.) appears to have referred to it in the *Iliad* as inducing forgetfulness of pain and sense of evil. Pedanios Dioscorides (1st century A.D.) described in detail the extraction of opium and its properties, which became universally known in the following centuries. Its use spread and the cultivation of the poppy in Asia Minor developed into a big industry. The Arab traders were chiefly responsible for transporting it to the remotest corners of Asia and spreading knowledge of its remarkable effects. Opium was probably introduced into India not earlier than the 9th century A.D., as there is no word equivalent to it in Sanskrit or Hindi. In the 15th century it was undoubtedly widely known and used both for medicinal and euphoric purposes. Opium was introduced into China by the Arabs in the 13th century; at first it was used entirely for medicinal purposes. In the 17th century opium smoking began and rapidly spread, and imports, especially from India, increased. In 1906, 27% of adult Chinese males smoked opium, and later, when the League of Nations was established, imports into China were curtailed and the use of opium restricted.

Habituation to Opium.—Certain properties of opium lead to its use in ever-increasing doses. The drug induces tolerance in the individual taking it, which means that the effects of the dose gradually decrease after it has been repeated for some time. Therefore the dose must be increased to give the same effects produced by the initial dose. Tolerance then becomes greater and the effective dose has to be correspondingly increased. In India there are records of individuals taking more than two ounces of opium a day for prolonged periods. Allied to toleration is the phenomenon of habituation, meaning psychical adaptation and mental conditioning to the repetition of an effect. This occurs also with other drugs, but is much more intense with opiates (*see* DRUG ADDICTION). The distortion of normal physiological processes resulting from prolonged use produces psychical dependence or habituation which manifests itself by requiring adequate amounts of the drug in the body to maintain physical and mental equilibrium. Once such dependence is established, the withdrawal of the drug is accompanied by abstinence phenomena. In man dependence gradually develops and although it may become extreme, it never arrives at a point when opiates are thereafter necessary to maintain life. In the initiated, habituation takes approximately six months, its development being favoured more by regular administration than by the quantity of the drug consumed.

Opium Eating.—This is mostly practised in Iran and India, and in the latter country on a larger scale than elsewhere. Studies by Sir R. N. Chopra show that in India little opium is used by the practitioners of indigenous and western medicine. It is, however, used extensively as a household remedy to relieve pain, especially in gastric and respiratory ailments. Though less common now, it is still the practice to give opium to infants to keep them quiet. Opium is usually taken in the form of a pill or as a solution in water. Because of restrictions on production and sale and an increase in price, its use greatly decreased after the early years of the 20th century. Indian addicts to opium eating can be divided into three groups: (1) About 50% take it for relief from ailments; (2) 20% to 30% take it to obtain escape from difficulty or worry; (3) 15% to 20% take it simply for pleasure. The dose taken by the first two groups is always small and not rapidly progressive, but in the third group it is large and ever-increasing. In a series of 1,000 cases, the average daily dose was found to be about ten grains. Habitual use of opium produces physical, mental and moral deterioration, proportional to the dose taken. Those taking small doses such as one to three grains daily show no apparent signs of the dulling of physical and mental faculties or the chronic toxaemia which are marked effects of larger doses.

Opium Smoking.—This is indulged in on a large scale in China, the Indian archipelago and India. It is the outcome of tobacco smoking and presents a serious problem. In India the habit was held in contempt, and stringent regulations were enacted against it. By 1950 opium smoking was, therefore, dying out in India, except in Assam and Madhya Pradesh where social and economic factors were responsible for its continuance. In Chopra's series of 300 cases, it was found that the habit had been contracted in 50% of the cases by association with other smokers purely for its euphoric (pleasurable) effects, in 33% for relief of ailments and in 17% to overcome worry and strain. Much larger quantities of opium were used for smoking than for eating, and the effect on the general health of even moderate smokers was much more marked. The dose ranged from 2 to 180 gr. a day, the average being 25 gr. The abstinence symptoms were also more severe. The racial factor was significant; although the average daily doses taken by a Chinese were two to three times larger than those of an Indian, the ill effects in the former were much less marked. In the case of the Indians, excessive indulgence seriously damaged health, caused loss of physical energy and deterioration of intellect and so reduced earning capacity and shortened life.

Opium is prepared for smoking by prolonged boiling with water and removing impurities in the form of scum, by evaporating and, lastly, by a process of toasting. In 1950 it was still not known whether the active principles become more potent through such a process. The preparations used in India are: (1) chandoo, which is opium prepared as above and which is also the form smoked in China; (2) madak, which is purified opium diluted with charred leaves of *Acacia arabica* (babal) (1 oz. opium = 2½ oz. madak); (3) opium dross, which is the residue left in the pipe after smoking and contains more than 7% of morphine and is smoked again. The smoker does not absorb more than one-tenth of the total amount of morphine contained in opium; there must, therefore, be other unrecognized factors responsible for the intense effects produced. The following table, compiled by W. E. Dixon and published in his article "The Drug Habit" in the *British Medical Journal*, vol. ii, p. 819 (1921), shows the composition of opium and tobacco smoke.

Analysis of Tobacco and Opium Smoke in Conditions Approximating Those Which Occur in Smoking

	Hydrocyanic acid	Pyridine	Nicotine	Ammonia	Carbon monoxide	Morphine
100 g. tobacco burnt as cigarettes	0 080 g.	0.146 g.	0.165 g.	0.360 g.	410 c.c.	—
100 g dross opium containing 7.35% morphine	0 010 g.	0.147 g.	—	0.395 g.	—	0.016 g. (0.1% chandoo smoke)

Source. W. E. Dixon, "The Drug Habit," *British Medical Journal*, 2:819 (1921).

Nicotine and carbon monoxide, which are the chief constituents of tobacco smoke responsible for its ill effects, are entirely absent in opium smoke. Morphine and pyridine bases are predominant and may be responsible for the profound effects by synergistic, or co-operative, action.

The method of smoking opium followed by the Chinese and Indian smokers is similar. The apparatus consists of a pipe, a stylet, a lamp and a headrest. The dose of prepared opium is heated over the flame at the end of the stylet until a small ball of roasted opium is formed. This is then pushed into the pipe head and the pipe is ready for smoking. The opium mass is held over a flame or live charcoal, while the smoker inhales deeply a number of times, taking the smoke well into the lungs. The actual smoking of the pipe takes about a minute; more prepared opium is taken if the smoker desires to continue. The effects produced are immediate since the lungs present a large surface for absorption.

OPIUM TRAFFIC. The use of the poppy and the coca leaf is quite ancient. However, its organized use for the purposes of commerce and revenue seems to have developed after 1700, in spite of protests against its use for other than medical and scientific purposes.

In 1783 Warren Hastings pronounced opium to be "a pernicious article of luxury which ought not to be permitted but for the purpose of foreign commerce only!" A few years later the directors of the East India company wrote, "If it were possible to prevent the use of the drug altogether except strictly for the purpose of medicine we would gladly do it in compassion to mankind," and Lord Ashley in 1843 proposed a resolution in the British parliament to the effect that the continuance of the opium monopoly and opium trade "was utterly inconsistent with the honour and duty of a Christian kingdom." Yet in the 20th century there were still countries whose colonies obtained large revenues from such monopolies.

The importation of opium into China by foreign traders led to the war of 1840 between Great Britain and China. The Chinese, in spite of the fact that they were not the victors and despite any pressure brought to bear upon them, still refused to legalize the opium trade. China was now open to the world and a huge smuggling trade in opium sprang up which gave rise to endless difficulties, both to the Chinese and to the British governments.

The second war broke out between China and Great Britain, with France as its ally, 15 years later, and, after its close, not only was the cultivation of opium in China itself permitted, but the import of opium from India was also legalized. Yet the Chinese government still continued to regard the use of opium as an important moral and economic question and, in the year 1906, it decided to put an end to the use of the drug within ten years. For this reason, in the following year, China entered into what is known as the "Ten Years' Agreement with India," by which China should cease the cultivation of the poppy and forbid the consumption of opium on the understanding that the export of Indian opium to China should be reduced in equal proportion and cease altogether in ten years. At first this undertaking was carried out faithfully by both parties concerned, and according to a statement made by Sir John Jordan at one of the meetings of the opium advisory committee, China in 1917 had almost freed itself from the curse of the poppy. Political troubles, however, broke out, effective government in China was suspended, and the production of opium in China became not only a great national but also an international problem.

International Action.—It was first realized in 1906 that if the Chinese government were able to suppress the opium evil, it must be assisted by other nations. In 1909 Pres. Theodore Roosevelt proposed that an international investigation should be made. As a result, an international opium commission met that year at Shanghai, at which 13 powers were represented.

The recommendations made at this meeting formed the basis of the first opium convention, which was drawn up at The Hague in 1912. The articles of this convention may be summarized as follows:

1. The distribution of raw opium to be controlled and the use of prepared opium to be gradually suppressed.
2. The export of raw opium to countries prohibiting its entry to be stopped and its export to countries restricting its import to be controlled.
3. The export and import of prepared opium to be prohibited except to those countries not yet ready to suppress its use.
4. The use of alkaloids of opium and its derivatives to be confined to medical and legitimate purposes; a government licence to be obtained by all persons engaged in the manufacture, sale, distribution, import and export of the drugs.
5. The last chapter of the convention consisted of clauses dealing with assistance to China and with certain obligations undertaken by China itself.
6. Before the convention came into effect, the adherence of the 34 nonsignatory powers in Europe and America was required.

International opium conferences were held at The Hague in July 1913 and June 1914, at which a number of powers ratified the convention. During World War I all action in this connection was suspended until the Paris peace conference in 1919. In the peace treaties of 1919–20, the signatory powers agreed that the ratification of these treaties should constitute a ratification of the convention of 1912 and the protocol adopted by the third opium conference of 1914 (according to which the convention should come into effect upon its ratification regardless of the nonsignatory powers).

The Advisory Committee and the League of Nations.—Under the covenant (article 23c), the duty of supervising the execution of agreements with regard to the traffic in opium and other dangerous drugs devolved upon the League of Nations. In order to carry out this obligation, the first assembly of the League constituted an advisory committee on opium and other dangerous drugs.

The committee, which sat once a year except in special circumstances, obtained certain important and definite results, such as additional ratifications to The Hague convention and the adoption by a large number of countries of an important certificate system. Under this system no government could allow the export from its territories of any dangerous drugs covered by The Hague convention, except on the production by the exporter of a licence from the importing country, certifying that the drugs in question were required for legitimate purposes.

The Import Certificate.—The council, on the recommendation of the advisory committee, invited the governments and members of the League to prepare an estimate of total annual requirements for the inhabitants of their territories for medical, scientific and other uses, with a view to proposing at some future date to the states concerned a new distribution of production which would limit the total output of raw material to the amount required for legitimate medical and scientific purposes. Subsequently two conferences met during the latter part of 1924 and the early months of 1925.

The 1924 conference did not find it possible to recommend the immediate complete suppression of the use of prepared opium, but drew up an agreement which embodied the substitution of government monopoly for other systems in force. It was held by the majority of members of the conference that no rationing could be enforced or total suppression imposed as long as a large illicit supply of opium remained uncontrolled. To this the representative of China objected, protesting against the refusal of the majority to take immediate steps to suppress opium smoking until producing countries should find it possible to control smuggling. The conference, in a protocol to the agreement, decided to take any necessary measures not already taken for the entire suppres-

sion within a period of 15 years of the consumption of prepared opium in the territories under their authority, this period to begin as soon as the effective execution of the measures required to prevent illicit exportation of raw opium from their territories had been undertaken by the poppy-growing countries. Provision under the agreement was made for a League commission to decide when these measures had been effectively executed. The agreements reached took the form of an agreement, a protocol and a final act. Instruments of ratification were deposited by all states represented at the conference, other than China and Japan. The agreement was, therefore, put into effect.

The Convention of 1925.—The result of the deliberations and discussions of the conference of 1925 was a convention providing for the more effective restriction of the production and manufacture of narcotics, and establishing stricter control and supervision of the international trade.

Among the suggestions made in the convention was the creation of a central board, whose task it would be to follow the course of international trade and the general acceptation of the export and import certificate system. The conference also drew up a protocol by which the signatory states, recognizing their obligations to establish such control over the production, distribution and exportation of raw opium as would put a stop to illicit traffic, agreed to take within five years of the date of the coming into force of the protocol such measures as might be required to prevent the smuggling of opium seriously interfering with the effective suppression of the use of prepared opium in those territories where such use was temporarily authorized. A final act, containing further recommendations, was drawn up.

Among these special mention may be made of a request to the council to consider the possibility of sending a commission to various opium-producing countries to study the difficulties connected with the limitation of the production of opium, and to advise as to what measures should be taken to make it possible to limit the production of opium in those countries to the quantities required for medical and scientific purposes.

The result of this final act is shown in the League of Nations commission of inquiry sent to Iran to report on the possible substitution of crops for the existing opium crops. This commission, which consisted of one American, one Italian and one French expert, presented its report to the council of the League of Nations at its meeting in March 1927.

As a result of this report, the representative of Iran made a number of proposals on behalf of his government and submitted an extensive program to the *majlis,* with recommendation for its enactment into law.

After the conference of 1925, India also undertook to reduce its export of opium 10% a year, with a goal of ceasing all exports.

The Convention of 1931.—The international convention of 1931 for limiting the manufacture and regulating the distribution of narcotic drugs introduced the obligatory estimate system to carry out the principle of limiting the manufacture and trade of narcotic drugs to medical and scientific needs. Each country is required to furnish, annually, advance estimates of the narcotic drugs needed for these purposes. These estimates are binding and determine the maximum amounts to be manufactured or imported in any given year. They are examined by the supervisory body, which is composed of four experts who are not government representatives.

Limitation of Manufacture.—Actions to limit manufacture of narcotic drugs and control international distribution were taken through six international conventions and agreements concluded between 1912 and 1936, supplemented by two international protocols concluded under the auspices of the United Nations in 1946 and 1948 respectively. Seventy-one sovereign countries being parties to one or more of these treaties, their application became universal, as is the problem which is the subject of this international legislation.

United Nations Commission on Narcotic Drugs.—The United Nations took over from the League of Nations, and the governments signatory to the treaties, by the protocol of 1946, vested in the appropriate agencies of the United Nations the powers formerly held by the League agencies. The council no longer existed; the U.N. Economic and Social council was given its powers and duties; the U.N. general assembly took over powers and duties from the assembly of the League. The Opium Advisory committee became the Commission on Narcotic Drugs, appointed by the Economic and Social council, and other modifications in form were made to correspond with the new situation.

At the sixth session of the U.N. Commission on Narcotic Drugs, held in New York city in 1950, an agreement was reached on principles to limit the production of opium to medical and scientific needs. The producing countries, Turkey, Iran, Yugoslavia and India, agreed with the drug manufacturing and consuming countries to limit areas of production and stocks in accordance with estimates to be supplied by each country to an international body.

A.)

OPON, a municipality (with administrative centre and 23 *barrios* or districts), on the small island of Mactan (area about 45 sq.mi.), province of Cebu, Republic of the Philippines. The island of Mactan, where Magellan was slain by the natives in March 1521, is separated from Cebu by a channel only about one mile wide. Pop. (1939) 33,426; 41 were whites. Opon is a shipping and commercial suburb of the municipality of Cebu, the harbour of which is sheltered by Mactan island. Its extensive groves of coconut trees afford supplies of copra, while maize (corn) and maguey are cultivated and fisheries are important. The vernacular is Cebuano, a dialect of Bisayan. Of the inhabitants aged 6 to 19 inclusive, 21.9% in 1939 attended school, while 35.1% of the population 10 years old and over was literate.

OPOPANAX. A gum resin obtained from the root of *Opopanax chironium,* formerly used as an antispasmodic medicine. The perfume known as opopanax is distilled from a *Commiphora.*

OPORTO, the second city of Portugal, about 3 mi. from the mouth of the Douro, in 41° 8′ N. and 8° 37′ W. Pop. (1930) 232,280; (1940) 262,309. The part of the city south of the Douro is known as Villa Nova de Gaia. Oporto is the see of a bishop. It is the true capital of northern Portugal, and the commercial and political rival of Lisbon, much as Barcelona is the rival of Madrid. Three main railway lines meet there—from Lisbon, from Valença do Minho on the northern frontier, and from Barca d'Alva on the northwestern frontier. Oporto is built chiefly on the north or right bank of the Douro; its principal suburbs are Bomfim on the east, Monte Pedral and Paranhos on the north, Villar Bicalho, Lordello and São João da Foz on the west, Ramalde, Villarinha, Matosinhos, Leça da Palmeira and the port of Leixões on the northwest. The mouth of the river is obstructed by a sandy spit of land which has been enlarged by the deposits of silt constantly washed down by the swift current; on the north side of this bar is a narrow channel varying in depth from 16 ft. to 19 ft. A fort in São João da Foz protects the entrance, and there is a lighthouse on a rock outside the bar. As large vessels cannot enter the river, a harbour has been made at Leixões (*q.v.*).

The approach to Oporto up the winding and fjordlike estuary is one of singular beauty. On the north the streets rise in terraces up the steep bank, built in many cases of granite overlaid with plaster, so that white is the prevailing colour of the city; on the south are the hamlets of Gaia and Furada, and the red-tiled wine lodges of Villa Nova de Gaia, in which vast quantities of port are manufactured and stored. The architecture of the houses and public buildings is often rather oriental than European in appearance. Palms, oranges and aloes grow side by side with the flowers and fruits of northern Europe, for the climate is mild and very equable, the mean temperatures for January and July—the coldest and the hottest months—being respectively about 50° and 70°. The design of some of the native river craft is peculiar—among them may be mentioned the *caicos,* high-prowed canoelike fishing boats, the *rascas* with their three lateen sails, and the *barcos rabello,* flat-bottomed barges with huge rudders, used for the conveyance of wine down stream. Two remarkable iron bridges, the Maria Pia and the Dom Luiz I, span the river. The first was built by Messrs. Eiffel and Company of Paris in 1876–77; it rests on a granite substructure and carries the Lisbon railway line across the Douro ravine at a height of 200 ft. The second was constructed in 1881–85 by a Belgian firm; its arch, one of the largest in Europe, has a span of 560 ft. The Douro is liable in winter to sudden and violent floods; in 1909–10 the water rose 40 ft. at Oporto, where it is confined in a deep and narrow bed.

The older quarters in the east are extremely picturesque, with their steep and narrow lanes overshadowed by lofty balconied houses. Overcrowding and dirt are common, for the density of population is nearly 13,000 per sq.m., or greater than in any other city of Portugal. The completion of the tramway system was long delayed. Ox-carts are used for the conveyance of heavy goods, and until late in the 19th century sedan-chairs were still occasionally used. As a rule the natives of Oporto are strong and of fine physique; they also show fewer signs of negro descent than the people of Lisbon. Their numbers tend to increase very rapidly; in 1864 the population of Oporto was 86,751, but in 1878 it rose to 105,838 and nearly doubled in the next half century. Many of the men emigrate to South America, where their industry usually enables them to prosper, and to return with considerable savings.

The cathedral, which stands at the highest point of eastern Oporto, on the site of the Visigothic citadel, was originally a Romanesque building of the 12th century; its cloisters are Gothic of the 14th century, but the greater part of the fabric was modernized in the 17th and 18th centuries. The interior of the cloisters is adorned with blue and white tiles, painted to represent scenes from the Song of Solomon. The Romanesque and early Gothic church of São Martinho de Cedo Feita is the most interesting ecclesiastical building in Oporto, especially noteworthy being the curiously carved capitals of its pillars. Though the present structure is not older, except in details, than the 12th century, the church is said to have been "hastily built" (*cedo feita, cito facta*) by Theodomir, king of the Visigoths, in 559, to receive the relics of St. Martin of Tours, which were then on their way hither from France. The Torre dos Clerigos is a granite tower 246 ft. high, built in the middle of the 18th century at the expense of the local clergy (*clerigos*); it stands on a hill and forms a conspicuous landmark for sailors. Nossa Senhora da Lapa is a fine 18th-century church, Corinthian in style; São Francisco is a Gothic basilica dating from 1410; Nossa Senhora da Serra do Pilar is a secularized Augustinian convent used as artillery barracks, and marks the spot at which Wellington forced the passage of the Douro in 1809. The exchange (*lonja*) is another secularized convent, decorated with coloured marbles. Parts of the interior are floored and panelled with polished native-coloured woods from Brazil, which are inlaid in elaborate patterns; there is a very handsome staircase, and the fittings of one large room are an excellent modern copy of Moorish ornamentation.

Other noteworthy public buildings are the museum, library, opera-house, bull-ring, hospital and quarantine station. The crystal palace is a large glass and iron structure built for the industrial exhibition of 1865. The English factory, built in 1790, has been converted into a club for the British residents—a large and important community whose members are chiefly connected with the wine and shipping trades. The English club gave its name to the Rua Nova dos Inglezes, one of the busiest streets, which contains many banks, warehouses and steamship offices. The Rua da Alfándega, skirting the right bank of the Douro and passing the custom house (*alfándega*), is of similar character; here may be seen characteristic types of the fishermen and peasants of northern Portugal. The Rua das Flores contains, on its eastern side, the shops of the cloth-dealers; on the west are the jewellers' shops, with a remarkable display of gold and silver filigree-work and enamelled gold. These ornaments are often very artistic, and are largely worn on holidays by women of the poorer classes.

Oporto is chiefly famous for the export of the wine which bears its name. An act passed on Jan. 29, 1906 defined "port" as a wine grown in the Douro district, exported from Oporto, and containing more than 16·5% of alcoholic strength. The vines from which it is made grow in the Paiz do Vinho, a hilly region about 60 m. up the river, and having an area of 27 m. in length by 5 or 6 in breadth. The trade was established in 1678, but the shipments for some years did not exceed 600 pipes (of 115 gallons each). In 1703 the British government concluded the Methuen treaty with Portugal, under which Portuguese wines were admitted on easier terms than French or German, and henceforward "port" began to be drunk (*see* PORT WINE). In 1747 the export reached 17,000 pipes. In 1754 the great wine monopoly company of Oporto originated, under which the shipments rose to 33,000 pipes. At the beginning of the 19th century the policy of the government more and more favoured port wine, besides which the vintages from 1802 to 1815 were splendid both in Portugal and in Madeira—that of 1815 has, in fact, never been excelled. For the next few years the grape crop was not at all good, but the 1820 vintage was the most remarkable of any. It was singularly sweet and black, besides being equal in quality to that of 1815. In 1852 the *Oidium* which spread over Europe destroyed many of the Portuguese vineyards. In 1865 *Phylloxera* did much damage, and in 1867 the second monopoly company was abolished. From this time the exports again increased. (*See* WINE.) A third of the population is engaged in the manufacture of cottons, woollens, leather, silk, gloves, hats, pottery, corks, tobacco, spirits, beer, aerated waters, preserved foods, soap or jewellery. The fisheries—chiefly of hake, bream and sardines—are extensive. Many tourists land at Oporto and visit Braga (*q.v.*), Bussaco (*see* BUSSACO, SERRA DE) and other places of interest, on their way to Lisbon.

The history of Oporto dates from an early period. Before the Roman invasion, under the name of Portus Cale, it was a town on the south bank of the Douro with a good trade; the Alani subsequently founded a city on the north bank, calling it *Castrum Novum*. About A.D. 540 the Visigoths under Leovigild obtained possession, but yielded place in 716 to the Moors. The Christians, however, recaptured Oporto in 997, and it became the capital of the counts of *Portucalia* for part of the period during which the Moors ruled in the southern provinces of Portugal. (*See* PORTUGAL: *History*.) The Moors once more became its masters for a short period, till in 1092 it was brought finally under Christian domination. The citizens rebelled in 1628 against an unpopular tax, in 1661 for a similar reason, in 1757 against the wine monopoly, and in 1808 against the French. The town is renowned in British military annals from the duke of Wellington's passage of the Douro, by which he surprised and put to flight the French army under Marshal Soult, capturing the city on the 12th of May 1809. Oporto sustained a severe siege in 1832–33, being bravely defended against the Miguelites by Dom Pedro with 7,000 soldiers; 16,000 of its inhabitants perished. In the constitutional crises of 1820, 1826, 1836, 1842, 1846–47, 1891 and 1908–10 the action of Oporto, as the capital of northern Portugal, was always of the utmost importance. In 1919 the monarchy was proclaimed at Oporto and lasted for three weeks. In Feb. 1927 it was the scene of an army rising and was bombarded during three days by government troops.

OPOSSUM (DIDELPHIS VIRGINIANUS), HANGING FROM A TREE WITH YOUNG

OPOSSUM, the name of several American marsupials, also applied in Australia to the phalangers (*q.v.*). True opossums are found almost throughout America (*see* MARSUPIALIA). They form the family Didelphidae, distinguished by the opposable first hind toe and by the dentition. They are small, nocturnal animals, with long noses, ears and tails, the latter being usually naked and prehensile. The opposable first hind toe is clawless and the tip is expanded into a flat pad. The other digits all bear claws. Mainly arboreal, they feed on birds, insects and fruit. The best known species of the type-genus is *Didelphis virginianus*, which is very common in the United States. It is nearly the size of a cat, gray in colour, the fur being woolly. When caught, it feigns death (hence the expression "playing 'possum"). The ova of opossums have a thin horny shell, and many more are produced

than can survive. The female produces 6 to 16 young, after a period of gestation of 14 to 17 days. At birth the immature and helpless young, only about ½ in. long, are placed by the mother in her pouch, where they cling to the nipples by their mouths. When big enough to leave the pouch, the young are often carried on the mother's back, holding on to her fur or clinging to her tail by their own prehensile tails.

The water-opossum (*Chironectes minimus*) has webbed feet (*see* WATER-OPOSSUM). Numerous other species inhabit various parts of America, being especially numerous in the tropical parts.

OPPELN, a town in the Prussian province of Silesia, Germany, on the Oder, 51 mi. S.E. of Breslau, on the railway to Kattowitz and at the junction of lines to Ratibor, Neisse and Tarnowitz. Pop. (1939) 52,806. Oppeln was a flourishing place at the beginning of the 11th century, and became a town in 1228. It was the capital of the duchy of Oppeln and the residence of the duke from 1163 to 1532, when the ruling family became extinct. Then it passed to Austria, and with the rest of Silesia was ceded to Prussia in 1742. In the partition of Upper Silesia between Germany and Poland in 1921 (*see* SILESIA) Oppeln was retained by Germany. It is the seat of the provincial administration of Upper Silesia, and contains the oldest Christian church in the district, that of St. Adalbert, founded at the close of the 10th century. It has a 15th-century palace on an island in the Oder. The industries of Oppeln include the manufacture of Portland cement, beer, soap, cigars, chemicals, clogs and lime; trade is carried on by rail and river in cattle, grain and the vast mineral output of the district, of which Oppeln is the chief centre. The upper classes speak German, the lower Polish.

OPPENHEIMER, J. ROBERT (1904–), U.S. physicist and scientist, was born April 22 in New York city. He was graduated from Harvard university in 1925, studied at Cambridge university until 1926 and then at Göttingen university, where he received his Ph.D. degree in 1927. He became a professor of physics at the University of California and at the California Institute of Technology in 1929. Dr. Oppenheimer devoted considerable time to research on the nature of matter, electricity and radiation, and was an authority on the structure of the atom. During World War II, the U.S. government placed him in charge of a special laboratory dealing with the technical problems involved in putting together the components of the atomic bomb. Dr. Oppenheimer planned the construction of the laboratory in an isolated area at Los Alamos, 20 miles from Santa Fe, N.M., and organized and directed its activities after its completion. He arrived at Los Alamos in March 1943 and under his direction, a galaxy of scientific stars worked in what was described as "probably the best-equipped physics laboratory in the world." Of Dr. Oppenheimer's role in the creation of the atomic bomb, secretary of war Henry L. Stimson, in his statement of Aug. 6, 1945, declared: "The development of the bomb itself has been largely due to his (Dr. Oppenheimer's) genius and the inspiration and leadership he has given to his associates." Oppenheimer also was a member of a four-man advisory group of leading U.S. scientists that worked with a government interim committee on establishment of postwar organizations to direct and control the use of atomic energy.

In Oct. 1947 he became director of the Institute for Advanced Study, Princeton, N.J., and on April 20, 1951, he was appointed a member of the 11-man committee of scientists to advise the United States director of defense mobilization.

OPPIAN (Gr. Ὀππιανός), the name of the authors of two (or three) didactic poems in Greek hexameters, formerly identified, but now generally regarded as two different persons. (1) Oppian of Corycus (or Anabarzus) in Cilicia, who flourished in the reign of Marcus Aurelius (emperor A.D. 161–180). According to an anonymous biographer, his father was banished to Malta by Verus. Oppian, who had accompanied his father into exile, returned after the death of Verus (169) and went on a visit to Rome. Here he presented his poems to Aurelius and regained the imperial favour for his family. Oppian subsequently returned to his native country, but died of the plague at the age of 30. His poem on fishing (*Halieutica*), of about 3,500 lines, dedicated to Aurelius and his son Commodus, is still extant. (2) Oppian of Apamea (or Pella) in Syria. His extant poem on hunting (*Cynegetica*) is dedicated to the emperor Caracalla, so that it must have been written after 211. It consists of about 2,150 lines, and is divided into four books, the last of which seems incomplete. It is inferior to the *Halieutica*.

A third poem on bird-catching (*Ixeutica*, from ἰξός, bird-lime), also formerly attributed to an Oppian, is lost; a paraphrase in Greek prose by a certain Eutecnius is extant.

The chief modern editions are J. G. Schneider (1776); F. S. Lehrs (1846); U. C. Bussemaker (Scholia, 1849); (*Cynegetica*) P. Boudreaux (1908). The anonymous biography referred to above will be found in A. Westermann's *Biographi Graeci* (1845). On the subject generally *see* A. Martin, *Etudes sur la vie et les oeuvres d'Oppien de Cilicie* (1863); A. Ausfeld, *De Oppiano et scriptis sub ejus nomine traditis* (1876). There are translations of the *Halieutica*, in English by Diaper and Jones (1722), and in French by E. J. Bourquin (1877).

OPPIUS, GAIUS, an intimate friend of Julius Caesar. He managed the dictator's private affairs during his absence from Rome. According to Suetonius (*Caesar*, 56), many authorities considered Oppius to have written the histories of the Spanish, African and Alexandrian wars which are printed among the works of Caesar. It is now generally held that he may possibly be the author of the last (although the claims of Hirtius are considered stronger), but certainly not of the two first. He also wrote a life of Caesar and the elder Scipio.

For a discussion of the whole question, *see* M. Schanz, *Geschichte der römischen Literatur* (2nd ed., 1898); Teuffel-Schwabe, *Hist. of Roman Literature* (Eng. trans., 1900); *see* also Cicero, *Letters*, ed. Tyrrell and Purser, iv. introd. p. 69.

OPPOSITION, in logic, means the various relations which can exist between judgments or propositions having the same subject and predicate but differing in quality or quantity. *See* LOGIC.

OPTICS. The study of Optics is usually divided into three parts: *Physical Optics*, *Physiological Optics* and *Geometrical Optics*. *Physical Optics* is primarily concerned with the nature and properties of light itself and is treated under LIGHT. *Physiological Optics* deals with the mechanism of vision, and is treated under VISION.

Geometrical Optics, which is the subject of this article, is the name applied to that part of Optics which deals with the properties of optical instruments such as telescopes, microscopes, photographic lenses, spectroscopes and the elementary lenses, mirrors and prisms from which they are constructed. As geometrical methods have been widely employed in inquiries concerning optical instruments, the name is not without historical justification. Nevertheless we shall have occasion to take exception to the validity of these methods in this field. They are in fact only admissible to an extent which deprives the historical theory of much of its utility. A brief account of this theory can, however, hardly be omitted here both on account of its historical importance and because even at the present day the majority of the literature on the subject is still couched in geometrical terms.

The basic conception of geometrical optics in this theory is the ray of light. The fact that light travels in straight paths was well known to the Greek mathematicians and the transition from optics to pure geometry was thus simple. More precisely in geometrical optics we assume that the ray of light continues in the same straight line while it travels in the same homogeneous medium. When it encounters a surface separating this medium from another, for example the surface between air and water, the ray proceeds in another direction from the point in which it meets this surface, and again continues to follow a straight path until another surface is reached. The new path may be in either the original or the new medium. In the former event the ray is said to be reflected, and in the latter refracted, at the surface of separation. We regard the whole continuous path of the light as a single ray, but distinguish the original and final portions as the incident ray and the emergent ray respectively. We may also apply the terms reflected ray or refracted ray as the case may be

to the latter.

The new directions are determined by simple geometrical laws. The law of reflection states (1) the incident ray, the reflected ray, and the normal to the surface at the point of reflection lie in one plane; (2) the incident and reflected rays lie on opposite sides of the normal; (3) the angles made by the incident and reflected rays with the normal are equal. The law of refraction states (1)

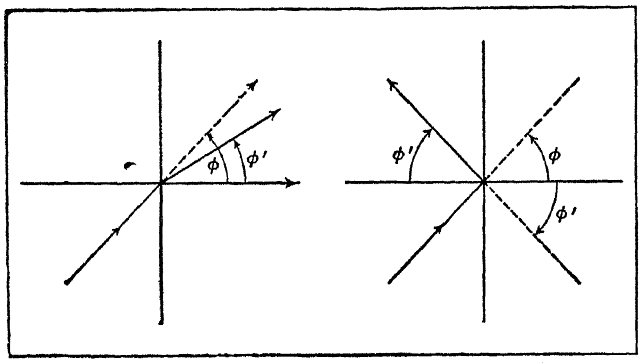

FIG. 1.—ANGULAR-SIGN CONVENTIONS, SHOWING (LEFT) REFRACTION: ANGLES OF INCIDENCE AND REFRACTION BOTH POSITIVE; AND (RIGHT) ANGLE OF INCIDENCE POSITIVE, ANGLE OF REFLECTION NEGATIVE

the incident ray, the refracted ray, and the normal to the surface at the point of refraction lie in the same plane; (2) the incident ray and the refracted ray lie on opposite sides of the normal; (3) the sine of the angle made by the incident ray with the normal bears a constant ratio to the sine of the angle made by the refracted ray with the normal. This ratio depends only on the composition of the two media separated by the surface, and is known as the relative index of refraction.

From a comparison of these two laws it will be seen that the law of reflection may be considered as a special case of the law of refraction, the relative refractive index being equal to either $+1$ or -1. Let us adopt the convention that angles are to be measured by the value of the anti-clockwise rotation needed to reach the ray position from the onward drawn normal. Thus in fig. 1a, the angles of incidence and refraction ϕ and ϕ' are positive, and if μ is the relative refractive index $\sin\phi = \mu\sin\phi'$. When reflection occurs the angle of reflection is opposed in sign to the angle of incidence (*see* fig. 1, right), and μ should therefore receive the value -1. It will be noted also that the reflected ray travels in the opposite direction to that contemplated in the law of refraction. As we shall see later all lengths entering into optical equations are either multiplied or divided by a refractive index and the double reversal of sign frees us from all difficulties regarding the signs of the quantities we employ. We are therefore enabled to dispense with any detailed consideration of reflecting instruments and can proceed to deal with refraction as an inclusive process.

For a reason which will become apparent later it is necessary for the reflecting and refracting surfaces used in optical instruments to approach very closely to ideal geometrical forms. The manufacturing processes by which the necessary degree of perfection can be reached impose severe limitations on the types of surface which may be employed, and in practice any surface but a portion of a sphere—with the plane as a special case—is rarely employed. We will therefore consider the refraction of light at a spherical surface

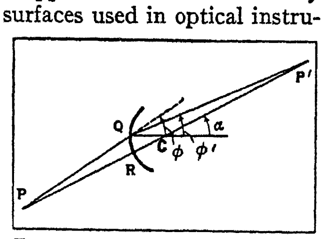

FIG. 2.—REFRACTION AT A SPHERICAL SURFACE

In fig. 2 let a ray passing through the point P be refracted at Q, a point on a spherical surface whose centre is at C. The refracted ray lies in the plane PQC containing the incident ray PQ and the normal QC, and it will therefore in general meet PC at some point P'. Let PC meet the surface in R and make an angle α with QC, and let ϕ and ϕ' be the angles of incidence and refraction. Then from the triangles PQC, $P'QC$

$$\frac{\sin\alpha}{\sin\phi} = \frac{PQ}{PC}, \quad \frac{\sin\alpha}{\sin\phi'} = \frac{QP'}{CP'},$$

and therefore by the law of refraction

$$\mu\,\frac{PQ}{PC} = \frac{QP'}{CP'}.$$

If now Q is near R, PQ and QP' differ from PR and RP' by small quantities of the second order, and the equation becomes

$$\mu\,\frac{PC-r}{PC} = \frac{r+CP'}{CP'}$$

or

$$\frac{\mu-1}{r} = \frac{\mu}{PC} + \frac{1}{CP'}$$

where r is the radius of the surface. It follows from this expression that all rays which, before refraction in the neighbourhood of R, pass through P, will afterwards pass through P'. Physically this means that light energy diverging from a particle of matter placed at P will converge to P' or alternatively will diverge in the new medium as though it were liberated at P'. The reunion of the rays at P' is thus of the greatest significance, and P' is called the image of the object P. If P' is so situated that the rays can actually pass through it the image is called real, but if it is so placed that they may merely be regarded as having originated there the image is called virtual. It should be observed that there is no need for the rays to have actually passed through the point P, that is to say we may deal with virtual objects as well as virtual images.

Consider now a succession of spherical surfaces which are all met by rays under the conditions just described. Corresponding to an object point P, real or virtual, the first surface forms an image at a definite point P_1. The point P_1 may be regarded as a source of rays falling upon the second surface, which forms an image P_2 of P_1. Each surface in turn forms a point image of that due to the preceding surfaces, and we conclude that the whole series of surfaces will form at a definite point P' in the final medium, an image, either real or virtual, of an arbitrary point P in the object space. The relation connecting P and P' may be shown to be unique and reversible, so that it is a matter of convention which of the spaces external to the system is regarded as the object space and which as the image space. It will be observed that we have not assumed axial symmetry in the system, so that this conclusion holds whether the centres of curvature of the various refracting surfaces are collinear or not.

Symmetrical Optical Instruments.—The refracting surfaces in a great majority of optical instruments are surfaces of

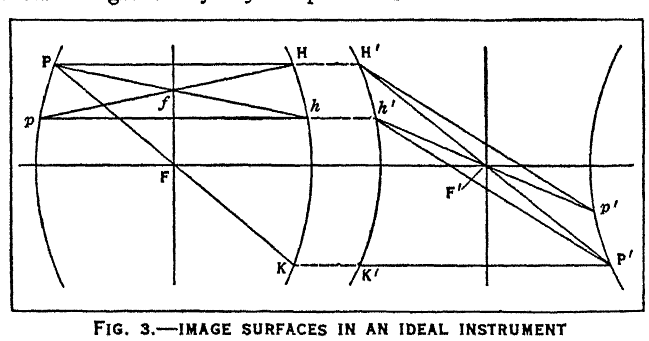

FIG. 3.—IMAGE SURFACES IN AN IDEAL INSTRUMENT

Determination of surfaces in which object and image are equal to one another, and also equal but inverted

revolution with a common axis of symmetry. In consequence of this rotational symmetry the theory of these instruments is particularly simple. Rays which lie initially in a plane containing the axis remain in that plane, and the general one-one correspondence between the points of the two spaces degenerates to a one-one correspondence between points of a plane.

The theory of the symmetrical instrument has been treated very comprehensively by Maxwell and later by Abbe on the assumption that this two dimensional point to point correspondence

holds. From symmetry it is clear that the image of each point on the axis is itself a point on the axis. Thus the axis is a self-conjugate ray for the system, that is to say the axis, regarded as a whole is its own image. Corresponding to the point at infinity on the axis in the object space there corresponds a point F' (*see* fig. 3), usually at a finite distance, in the image space. This is named the second principal focus of the system. Then all rays which in the object space are parallel to the axis will be refracted so as to pass through F' in the image space, and conversely all rays in the image space which pass through F' correspond to rays which are parallel to axis in the object space. Similarly there is a point F on the axis in the object space such that all rays passing through F emerge in the image space as rays parallel to the axis. This point is called the first principal focus of the system. Since the incident portion of any ray refracted parallel to the axis lies in the same axial plane as the emergent portion, the two will meet if produced in some point H. The point thus determined on the incident ray is at the same distance from the axis as the whole of the emergent portion of the ray, and the height of the image of an object extending from H to the axis is equal to the height of the object itself, a fact usually expressed by saying that the transverse magnification is 1. The locus of points H determined in this manner is therefore called the first unit surface. It is to be considered as situated entirely in the object space.

In a similar way by considering the intersections of the incident and emergent portions of rays which pass through F' in the image space we determine the second unit surface situated in the image space. Clearly these two surfaces have rotational symmetry about the axis and are conjugate to one another, that is, the one surface is the image of the other, and any ray striking the first unit surface in the point H will follow a path in the image space passing through H' in the second unit surface where HH' is parallel to the axis. Now let $PHH'F'P'$ and $PFKK'P'$ be two rays meeting in P and P', the former being parallel to the axis in the object space and the latter in the image space. Let these two parallel portions be at equal distances from the axis and on opposite sides of it. The image extending from P' to the axis is of equal height to an object lying between P and the axis, and is inverted. P and P' therefore trace out conjugate surfaces corresponding to the transverse magnification -1. F and F' are the mid-points of PK and $H'P'$ and the new surfaces are therefore precisely equal to the corresponding unit surfaces but face opposite ways. Now let $phh'F'p'$ be another ray parallel to the axis in the object space meeting the unit surfaces in h and h' and the negative unit surfaces in p and p'. From symmetry Ph and pH intersect in a point f situated in the plane through F normal to the axis of the system, and from the congruent triangles $h'F'P'$, $H'F'p'$, $h'P'$ and $H'p'$ are parallel. In other words the normal plane through F is conjugate to the surface at infinity in the image space, and similarly the normal plane through F' is conjugate to the infinitely distant surface in the object space. By taking a pair of rays whose distances from the axis are in any assigned ratio we can construct the conjugate surfaces for this magnification.

It is a simple matter to show that the object space surfaces are all similar and similarly situated about F, and the image space surfaces also similar and similarly situated about F'. Since we have taken the ratio of the distances of corresponding points from the axis as the measure of the magnification, any corresponding secondary elements of length (that is elements normal to the plane through the axis of symmetry) in the image and object surfaces are in this ratio. Now consider two parallel incident rays inclined to the axis, not intersecting it but situated symmetrically with respect to it, the separation between them being small. They determine on every constant magnification object surface a secondary element of unvarying length. In the image space these rays intersect in a point f' in the focal plane through F'. The lengths of the secondary elements intercepted on the constant magnification surfaces in the image space are therefore proportional to the distances of the points of intersection from f'. In other words these surfaces must be similarly situated with respect to any point f' in the focal plane.

It follows that all the constant magnification surfaces are planes normal to the axis, and that the magnification in every such plane is uniform in all directions. All the properties of the system may therefore be related to the points in which these planes meet the axis of symmetry. With the aid of rays passing through F and F' (fig. 4) we readily prove, if U and U' are the

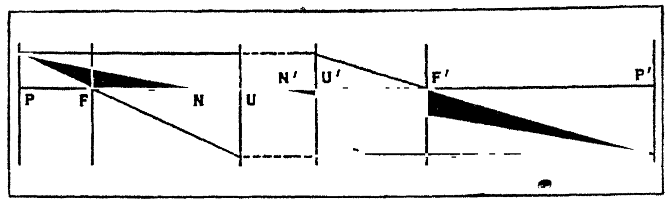

FIG. 4.—COLLINEAR IMAGERY SHOWING THAT ANY RAY THROUGH THE NODAL POINT N EMERGES IN A PARALLEL DIRECTION THROUGH N'

unit points, that is the points in which the unit planes meet the axis, and P and P' are any pair of conjugate axial points

$$\text{transverse magnification} = \frac{FU}{FP} = \frac{P'F'}{U'F'}$$

so that conjugate points are determined by $FP \cdot P'F' = FU \cdot U'F'$. If we draw through f a straight line fN, parallel to the direction of the emergent rays arising from f, to meet the axis in N, we have $FN = U'F'$. The conjugate point N' by the above relation is given by $N'F' = FU$. These points, from the circumstance that the incident and emergent rays through them are parallel to one another, are called the nodal points of the system. FU and $U'F'$ are named the first and second focal lengths of the system. When these two focal lengths are equal the unit points coincide with the nodal points and are frequently called the principal points.

It is easy to show with a system consisting of a single surface that if an object point is moved along the axis, the image moves in the same direction. It follows that this holds also for any compound instrument, and hence FU and $U'F'$ are always measured in the same direction. There are thus only two types of system—positive systems, illustrated in fig. 4, in which the principal foci F and F' are reached by proceeding from U and U' towards the real distant part of the corresponding space (the focal lengths thus being positive), and negative systems in which all these signs are reversed. The unit planes are usually situated close to or between the extreme refracting surfaces of the lens, and in a negative instrument all the real portions of the object space and of the image space are thus on a single side of the respective focal planes. It follows that such a negative system cannot yield a real image of a real object, and since the focal planes separate upright from inverted images, there is no inversion if either object or image is real. With a positive lens we can obtain a real inverted image of a real object, but if there is no inversion either the object or the image or both are virtual.

As we have based this discussion on the general correspondence of object and image points, the conclusions hold whenever the initial assumptions are satisfied irrespective of the way in which the system is constructed. Had we first considered the properties of a single spherical surface and extended the result to a combination of several such surfaces, our conclusions would not necessarily have applied to a system in which aspherical surfaces are employed.

Formulae are frequently used in which measurements are made from the unit points instead of from the principal foci. If we denote the transverse magnification by m, we have

$$\frac{PU}{FU} = 1 - \frac{1}{m}, \quad \frac{U'P'}{U'F'} = 1 - m, \quad \frac{U'P'}{PU} = -m\,\frac{U'F'}{FU}$$

and $\dfrac{FU}{PU} + \dfrac{U'F'}{U'P'} = 1$. When the two focal lengths have the common value f the last two equations become

$$m = -\frac{U'P'}{PU}, \text{ and } \frac{1}{PU} + \frac{1}{U'P'} = \frac{1}{f}.$$

Systems which yield on a uniform scale a plane image of a plane object (and incidentally a plane image of every plane object) are admirably fitted for many practical purposes, for example the photographic reproduction of maps. The scheme we have just described, which is known as collinear imagery, has therefore been widely used as a standard with which the performance of real instruments may be compared. It is of value as an artificial reference frame, rather than as a scheme to which real instruments tend to conform.

The Wave Theory and Lenses.—We will now consider the properties of lenses according to the wave theory of light. The postulates of this theory, which have been justified by the most varied experiments, are that monochromatic light may be regarded as an undulatory disturbance of unvarying period which spreads out in all directions from the source at a uniform speed which depends only on the medium in which it is travelling. In common with other forms of wave motion the disturbance at a given instant at any point may be obtained by replacing the actual wave system by a system of secondary sources of proper intensities and phases distributed over a surface. The statistical distribution of light energy is assumed to be that of the energy distribution of the wave system on the assumption that a long train of waves is involved. On this basis the phenomena observed in the neighbourhood of an optical image—that is the point where the energy of the wave motion has its greatest value through the contributions of the secondary sources arriving in the same phase—have been very satisfactorily accounted for. It is shown in treatises on Physical Optics (*see* LIGHT) that these assumptions involve the propagation of light in straight paths normal to the wavefront (so that the rays of the geometrical theory are to be regarded as normals to the wavefront), and changes in the directions of these paths in agreement with the laws of reflection and refraction provided the relative refractive index is made equal to the ratio of the times taken by light to travel equal distances in the new and old media. It would therefore appear that we should find agreement between the deductions to which we are led by the geometrical and the wave theories. This conclusion however is incorrect. An essential condition in deducing the law of rectilinear propagation is that the wavefront should be of considerable lateral extent. When light approaches a real focus this condition is violated, with the result that the direction of propagation in fact is not constrained to the straight paths assumed in the geometrical theory. It is therefore not surprising to find that while the geometrical theory indicates correctly the positions in which images are formed and the conditions which should be satisfied if an instrument is to yield images of the highest quality, it is misleading in the character of the image it leads us to expect, and the effects to be observed in the neighbourhood of the image. The two theories also differ in the course they would lead us to adopt when any of the conditions corresponding to perfect imagery are not satisfied.

Since the relative refractive index depends only on the relative speed with which light travels in the two media we may, by assigning the value unity arbitrarily as the refractive index of a suitable substance under specified physical conditions, obtain an absolute refractive index for any other substance. As an absolute standard medium empty space is taken, but for practical purposes the refractive index of air at standard temperature and pressure is adopted. We shall hereafter, when we speak of refractive index, imply the absolute refractive index of a substance on one or other of these conventions. We will now show that the two focal lengths of any symmetrical optical system are in the ratio of the refractive indices of the two external media.

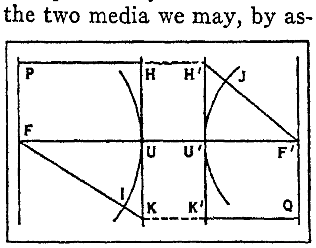

FIG. 5.—RATIO OF FOCAL LENGTHS

Let a plane wave normal to the lens axis in the object space of refractive index μ travel from the position PF, fig. 5, until, after being converted by the instrument into the spherical wave $U'J$, in the image space of refractive index μ', it reaches the principal focus at F'. Let another plane wave in the image space travel in the reverse direction from $F'Q$ to F. As different parts of the same wavefront take equal times to reach the focus, the time taken by the light to travel by the path $PHH'JF'$ is equal to that taken along the axial path $FUU'F'$, and similarly the paths $QK'KIF$ and $F'U'UF$ take equal times. The time taken to traverse the same axial path $FUU'F'$ is independent of the direction, and the times for all these paths are thus equal. Now the times taken along PH and FU are equal, and the times along the equal distances $U'F'$ and JF' in the same medium are equal. It follows that the time taken to travel from U to U' exceeds that between H and H' by the time needed to traverse the distance $H'J$. Similarly the time for the journey UU' exceeds that between K and K' by the time taken to cover the distance IK. Now if H and K are at equal distances y from the axis the time taken to travel between H and H', from the symmetry of the instrument, is equal to that taken between K and K'. It follows that $\mu\cdot IK=\mu'\cdot H'J$, or

$$\mu[\{(FU)^2+y^2\}^{\frac{1}{2}}-FU]=\mu'[\{(U'F')^2+y^2\}^{\frac{1}{2}}-U'F'];$$

that is, if the terms in y^4 and higher powers of y are negligible,

$$\tfrac{1}{2}\mu\,\frac{y^2}{FU}=\tfrac{1}{2}\mu'\,\frac{y^2}{U'F'},$$

and since this holds for finite values of y we must have

$$FU:U'F'=\mu:\mu'.$$

In particular if the two external media are composed of the same kind of matter the two focal lengths are equal to one another.

Let us now consider the possibility, according to the physical criterion of equality of time along the geometrical rays, of collinear imagery. Let $PQRS$ be four object points and $P'Q'R'S'$ their images. Denote by $\{AB'\}$ the distance light would travel in the medium of refractive index unity in the time taken to travel from A through the instrument to B'. Then since with geometrically perfect imagery the time between two conjugate points is equal by all paths,

$$\begin{aligned}
\{PP'\} &= \mu PQ + \{QP'\} = \mu PS + \{SP'\}\\
\{QQ'\} &= \{QR'\} + \mu' R'Q' = \{QP'\} + \mu' P'Q'\\
\{RR'\} &= \mu RS + \{SR'\} = \mu RQ + \{QR'\}\\
\{SS'\} &= \{SP'\} + \mu' P'S' = \{SR'\} + \mu' R'S'
\end{aligned}$$

or $$\mu(PQ+RS-PS-RQ)=\mu'(P'Q'+R'S'-P'S'-R'Q').$$

Now without altering the configuration of the figure $PQRS$ we may, if the focal lengths of the system are finite, make the scale of the figure $P'Q'R'S'$ as large or as small as we like by moving $PQRS$ as near or as far from the lens as we like. In particular we may make each dimension of the figure $P'Q'R'S'$ smaller than any assigned finite small length. This relation cannot therefore hold, and collinear imagery is not possible for a system of finite focal length. In other words it is impossible to construct an optical system having a finite focal length which will refract all rays from any given object point so as to pass through a single image point. Using terms significant in the wave theory, the time taken to travel through the instrument between a point in the object space and a point in the image space cannot be independent of the path followed for an arbitrary choice of the object point. When the focal length is not finite the image is a copy of the object on uniform transverse and longitudinal scales, and collinear imagery is achieved when the two refractive indices are numerically equal and the object and image are congruent figures. The most familiar example is afforded by reflection at a plane mirror, where we suppose the two external refractive indices differ only in sign. (*See* MIRROR.)

The Size of a Point Image: Resolving Power.—The extent of the divergence between the two theories may be illustrated by considering properties of importance to the user of the instrument. First we will consider the size of the image of a point source. Of the spherical wave which spreads out from the source only a portion can enter the instrument, and corresponding to the perfect reunion of the rays in an image point we have an emergent

wave of spherical form. In fig. 6, BAC represents a wave-front filling the aperture BC: the wave is in the form of a portion of a concave sphere of which F is the centre. According to geometrical optics the image is the point F, and is formed by rays filling the cone BFC of which AF is the axis and α is the semi-angle. By the principles of physical optics the disturbances produced by the train of waves are the same as would be produced by a suitable series of disturbances situated in the wave-front BAC. Now any disturbance at A gives rise to a spherical wave with A as centre. If we confine ourselves to a region around F of dimensions small compared with AF we may consider the wave from A to be a plane wave PP' at F. Similarly from B and C we get plane waves QQ' and RR' making angles $\pm\alpha$ with PP'. Now all parts of the wave front BAC are equidistant from F, and the component disturbances at F are therefore all in the same phase—that is to say, all the displacements are in the same direction and reach their maximum values at the same instant.

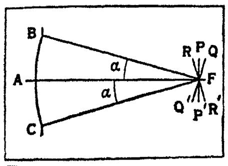

FIG. 6.—DEPENDENCE OF RESOLVING POWER ON APERTURE

The energy of the wave motion is therefore a maximum at F, for there the co-operation is as great as possible. The wave from B will, however, have already passed beyond P, and that from C will not yet have reached P by the time the wave from A has arrived at the position PFP'. To find the disturbance at P we therefore have to take the displacement at B when the wave-front BAC is short of the position shown by the distance PQ, and similarly the displacement at C when this wave-front has advanced beyond the position shown by the distance PR. That is to say the component displacements at P vary in phase, the total range being found by measuring the difference of path, *i.e.*, the length $2PF\sin\alpha$, along the train of waves in the direction of their motion. Now if P is near enough to F the differences of phase are small, and the displacements differ very little from those at F; in other words at points very close to F the light energy is practically the same as at F, so that the image is of finite dimensions, and not a point. As P moves farther away from F the range of phase increases, and at a certain stage we begin to receive contributions from points near B which tend to neutralize those contributed from points near C, so that the light energy as we pass through these positions of P diminishes rapidly. Finally we reach a position of P at which the range of phase is great enough for the various contributions to neutralize one another, or at least to so nearly neutralize one another that our impression on looking at this point is that we have reached or passed the edge of the image.

Since the changes of intensity are due wholly to differences of phase, the image edge will be reached when the difference of path is some constant θ times the wave length λ of the light, *i.e.*,

$$2PF\sin\alpha=\theta\lambda$$

or

$$\text{image diameter}=2PF=\frac{\theta\lambda}{\sin\alpha}=d.$$

If λ_0 is the wave length of the light in the standard medium $\lambda_0=\lambda\mu$, and the last fraction becomes $\theta\lambda_0/\mu\sin\alpha$. As the aperture which limits the light passing through the instrument is reduced, $\sin\alpha$ decreases, and the size of the image increases. If two near object points are to be distinguished on examining them through the instrument their images must be separate, and the resolving power of the instrument, as its capacity for rendering distinct images of near objects is called, is measured by the reciprocal of the image diameter, that is by $\mu\sin\alpha/\theta\lambda_0$. With light of a given wave length the denominator is invariable, and as $d\mu\sin\alpha$, as we shall see later, is unaltered by refraction, the resolving power of an instrument is measured by $\mu'\sin\alpha'$, where the accented quantities relate to the object space. On account of its importance in microscopy this quantity is known as the numerical aperture of the instrument. The utility of an optical instrument evidently depends upon the variation in path having a small value compared with the wave length of the light used. Since the wave length is very small, a very close approach to the theoretical form, as has already been mentioned, is necessary in the refracting surfaces.

Depth of Focus.—We will now consider according to the two theories how far we may expect to be able to depart along the axis of the instrument from the ideal focus F, and still retain a satisfactory image. According to geometrical optics light rays fill the cone BFC, fig. 7, and the image in the plane XY will be a circle of diameter IJ. The image is considered satisfactory if IJ does not exceed a certain diameter, say d, so that the permissible range for G is given by the condition

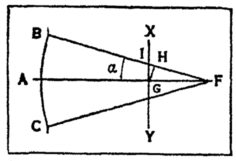

FIG. 7.—DEPTH OF FOCUS

$$FG=\tfrac{1}{2}d\cot\alpha$$

or very approximately

$$FG=d\cdot\frac{I}{a},$$

where I is the distance of the image from the principal point and a is the effective diameter of the lens aperture, supposed situated in the unit plane. The important feature of this formula is that the depth of focus is inversely proportional to the first power of the diameter of the aperture.

Let us now consider the same problem from the point of view of the wave-theory. Instead of relying on the geometrician's hypothesis we are able to rest on the well attested fact that an image begins to appear less sharp when the extreme difference between the phases of the component waves at the centre of the image reaches a definite value, that is to say when the path difference at G amounts to $\phi\lambda$ where ϕ is a definite number. This criterion differs from that considered on the geometrical theory less radically than might at first sight appear, for the existence of an appreciable phase difference at the image centre means that in this neighbourhood the light energy is less: but the total light energy of the waves is absorbed wherever the plane may be placed, and energy removed from the central regions must therefore appear in some other place. But to say that an appreciable amount of energy is found farther from the centre is only another way of stating that the image is sensibly enlarged.

Resuming, however, the determination of the range for G, the distance of this point from B differs by an unimportant amount from BH, where GH is perpendicular to BF. Since the extreme paths obviously arise from A at one limit and marginal points such as B at the other, and since all path lengths to F are equal, the extreme path difference is the difference between FG and FH, or $FG(1-\cos\alpha)$ or

$$FG=\frac{\phi\lambda}{1-\cos\alpha}$$

Now $a=2I\sin\alpha$, and therefore approximately

$$FG=8\phi\lambda\left(\frac{I}{a}\right)^2.$$

This formula indicates a law of a quite different type from that derived geometrically, the range varying inversely as the square of the aperture diameter, instead of as the first power.

The Depth of Field.—By reasoning of a character essentially similar to that of the foregoing section we can find expressions for the nearest and greatest distances x and x' at which objects may be situated from the lens for their images to appear sharp on a screen focussed for a distance X. According to the geometrical theory the conditions are

$$\frac{1}{x}-\frac{1}{X}=\frac{1}{X}-\frac{1}{x'}=\frac{d}{Ia},$$

and the conditions derived from a limiting difference of path are

$$\frac{1}{x}-\frac{1}{X}=\frac{1}{X}-\frac{1}{x'}=\frac{8\phi\lambda}{a^2},$$

where the symbols bear the same meanings as in the previous section. Thus assuming the objects are at a considerable distance from the lens, so that I is approximately equal to the focal length of the lens, according to geometrical optics the focal

length of the lens and the aperture are equally important, the range being inversely proportional to both. On the other hand according to the wave theory the focal length has nothing whatever to do with the question, and the range is inversely proportional to the square of the aperture. Both theories, it will be observed, indicate the selection of the same plane for the theoretical focus to secure the utmost sharpness for all objects between two given extreme planes.

It should be unnecessary to point out that the problems on which it has been shown that the two theories differ so widely, are of much practical importance in the use of optical instruments. As an example in photography, when considerable depth of focus is required, the geometrical formula is likely to lead to the use of an unnecessarily small stop, thereby involving not only a longer exposure, but also, through the tendency of a small stop to cause loss of sharpness, a poorer negative.

The Eikonal.—The examples we have just considered show that a complete investigation of the properties of lenses involves the determination of the time taken by light to reach any given point in the neighbourhood of the geometrically determined image, by both stationary and non-stationary routes (that is along "rays" and along other paths), as a preliminary to the calculation of the energy of the wave motion there. The computation of the time by non-stationary routes may be omitted if the surface where the secondary sources are placed is selected in the image space and the times from the source to this surface are determined for stationary routes only. In practice the energy distribution will not be determined in routine calculations, as typical calculations or observations will show the effects caused by departing from strict equality of path by different amounts, for each of the types of variation encountered in well-corrected systems.

All calculations will therefore relate to the geometrical paths, but variation in the lengths of these paths rather than their distances from a mean point in the neighbourhood of an image is to be regarded as the significant factor on which the quality of the image depends. The two sets of magnitudes are not independent, and we proceed to find the connection between them.

Take origins of rectangular co-ordinates in both object and image spaces. Suppose in the first space that a point source of light is situated at (x, y, z) in the object space. Light is radiated from this point in all directions, and some traverses the optical system and finds its way into the image space. Generally the wave-front in the image space will be a curved surface, and the normals or rays at different points of this surface differ in direction. A particular emergent ray may therefore be specified by its direction cosines. Let these be (L', M', N'), and suppose also that (ξ', η', ζ') is a point on this ray. The disturbance has taken a definite time to reach (ξ', η', ζ') from (x, y, z): let the corresponding optical path length, that is, the distance light travels in a standard medium in this time, be denoted by $\mathcal{V}$. Let $\mathcal{V}+\delta\mathcal{V}$ be the path length for a neighbouring ray starting from (x, y, z) and finishing at $(\xi'+\delta\xi', \eta'+\delta\eta', \zeta'+\delta\zeta')$, the final direction being $(L'+\delta L', M'+\delta M', N'+\delta N')$. If μ' is the refractive index of the final medium, the second path exceeds the first by

$$\mu'\{(L'+\delta L')\delta\xi'+(M'+\delta M')\delta\eta'+(N'+\delta N')\delta\zeta'\}$$

since the wave-front, which marks the locus of points optically equidistant from (x, y, z), is normal to the ray. Now suppose that the tangent planes to the wave-fronts at (ξ', η', ζ') and $(\xi'+\delta\xi', \eta'+\delta\eta', \zeta'+\delta\zeta')$ pass through the image space origin. Then

$$L'\xi'+M'\eta'+N'\zeta'=0,$$

$$(L'+\delta L')(\xi'+\delta\xi')+(M'+\delta M')(\eta'+\delta\eta')+(N'+\delta N')(\zeta'+\delta\zeta')=0,$$

and these conditions enable the expression we have found for the path difference to be written

$$-\mu'\{\xi'\delta L'+\eta'\delta M'+\zeta'\delta N'\}=\delta\mathcal{V} \qquad (1).$$

Now L', M', N' are connected by the relation

$$L'^2+M'^2+N'^2=1,$$

and therefore only two of them, say M' and N', may be regarded as independent variables. On eliminating L' (1) becomes

$$-\mu'\left(\eta'-\frac{M'}{L'}\xi'\right)\delta M'-\mu'\left(\zeta'-\frac{N'}{L'}\xi'\right)\delta N'=\delta\mathcal{V}.$$

Since $\mathcal{V}$ is now regarded as a function of M' and N', for any small variations of M' and N' we shall have

$$\delta\mathcal{V}=\frac{\partial\mathcal{V}}{\partial M'}\delta M'+\frac{\partial\mathcal{V}}{\partial N'}\delta N',$$

and, since M' and N' may be varied independently, we find, by comparing these equations,

$$\mu'\left(\eta'-\frac{M'}{L'}\xi'\right)=-\frac{\partial\mathcal{V}}{\partial M'},\quad \mu'\left(\zeta'-\frac{N'}{L'}\xi'\right)=-\frac{\partial\mathcal{V}}{\partial N'}.$$

Now $\eta'-\frac{M'}{L'}\xi'$ and $\zeta'-\frac{N'}{L'}\xi'$ are invariants for any given ray, and represent the y' and z' co-ordinates of the intersection of the ray with the plane $x'=0$. If we understand that y' and z' are the co-ordinates of a point in this plane we may write these equations

$$\mu'y'=-\frac{\partial\mathcal{V}}{\partial M'},\quad \mu'z'=-\frac{\partial\mathcal{V}}{\partial N'} \qquad (2)$$

If then we know $\mathcal{V}$ as a function of M' and N', that is to say if we know how the length of the optical path from the source to a plane through the image space origin varies as the direction of this plane alters, we can find where the common normal to this plane and the wave meets an arbitrary fixed plane through the origin.

If, instead of starting with a source of light at a known point of the object space, we had assumed it to be situated in the image space, some of the light diverging from this point would reach the lens and after refraction would emerge into the object space. We could take $\mathcal{V}'$ as a measure of the time taken by the light to reach a plane in the direction (L, M, N) passing through the object space origin, and obtain the equations

$$\mu y=\frac{\partial\mathcal{V}'}{\partial M},\quad \mu z=\frac{\partial\mathcal{V}'}{\partial N} \qquad (3)$$

for the point (y, z) in which the common normal to the wave-front and the plane $L\xi+M\eta+N\zeta=0$ meets the plane $x=0$. The change of sign which will be observed on comparing equations (2) and (3) is due to the assumption that the positive directions of the axes are unaltered, so that a positive displacement of (ξ, η, ζ) corresponds to a decrease in the time $\mathcal{V}'$.

The function $\mathcal{V}$ suffers from the grave disadvantage that it is unsymmetrical, the variables in the object space being point co-ordinates, and in the image space direction cosines. A function which is symmetrical is at once obtained by considering the particular case in which the source of light is at infinity. It is inconvenient to include in the function the infinite term representing the length of the path between the source and a reference position near the lens, so the path is measured from the wave-front which passes through the object space origin. Since all points on the same wave-front are at the same optical distance from the source, $\mathcal{E}$, the new finite path length, which is a function of (M, N, M', N'), differs from $\mathcal{V}$ only by a constant, and, as in the case of $\mathcal{V}$, the equations

$$\mu'y'=-\frac{\partial\mathcal{E}}{\partial M'},\quad \mu'z'=-\frac{\partial\mathcal{E}}{\partial N'} \qquad (4)$$

are satisfied. In a similar way from $\mathcal{V}'$, by placing the source at infinity in the image space in the direction L', M', N', and rejecting the constant infinite part of the path, we obtain a finite function $\mathcal{E}'$ having (M, N, M', N') as its variables and satisfying the equations

$$\mu y=\frac{\partial\mathcal{E}'}{\partial M},\quad \mu z=\frac{\partial\mathcal{E}'}{\partial N} \qquad (5)$$

Now $\mathcal{E}$ and $\mathcal{E}'$ measure the time taken by the light to travel between the same two planes in opposite directions along the stationary path. This stationary path between two planes is unique and independent of the curvature of the wave-front at either

plane. Moreover the speed of light is independent of direction. It follows that $\mathcal{E}$ and $\mathcal{E}'$ are equal, and, since they are expressed in terms of the same variables, they must be identical. This symmetrical function of the direction cosines, which is one of the Characteristic Functions introduced into Optics by Hamilton, will be referred to as the Eikonal, a name proposed by Bruns.

In the application of this function the planes $x=0$ and $x'=0$ will be chosen to coincide with the object and image planes, or at least to be parallel to them. Equations (4) and (5) then show how this function, which itself expresses the length of a path carried through the refracting surfaces, and is thus particularly suitable for investigations according to the wave theory, enables the points in which rays travelling in specified directions meet the object and image surfaces to be found.

Focal Lengths and Principal Foci.—The rays, being the normals to the wave front, are the loci of points for which the path is stationary for slightly displaced routes, and conjugate foci are points of a particular path between which the path length is stationary for larger deviations. In an axially symmetrical system we can see immediately that a pair of such points for a skew ray (that is to say, a ray which does not lie entirely in an axial plane) are the intersections of any axial plane with the incident and emergent rays. By considering a ray in an axial plane as the limiting position of a skew ray, we can extend the definition to all rays. We shall call such conjugate points secondary foci. We proceed to find the positions of the principal secondary foci and the magnitudes of the corresponding focal lengths.

Take the axes of x and x' in coincidence with the axis of symmetry, so that $\mathcal{E}$ may be regarded as a function of three variables only, viz., $\frac{1}{2}\mu^2(M^2+N^2)$, $\mu\mu'(MM'+NN')$ and $\frac{1}{2}\mu'^2(M'^2+N'^2)$. Denoting these by a, b, c respectively, and differentiation by the addition of a suffix, equations (4) give

$$y'+\mu M\mathcal{E}_b+\mu' M'\mathcal{E}_c=z'+\mu N\mathcal{E}_b+\mu' N'\mathcal{E}_c=0 \qquad (5)$$

that is to say, the ray goes through the point $(\rho' L', Y', Z')$ distant ρ' along the ray from the reference plane $x'=0$, where $\rho'=\mu'\mathcal{E}_c$ provided

$$Y'=-\mu M\mathcal{E}_b,\ Z'=-\mu N\mathcal{E}_b \qquad (6)$$

These equations show that at this point the ray goes through a point in the axial plane containing the infinitely distant origin of light (L, M, N). In other words the secondary principal focus lies on the ray at the distance $\mu'\mathcal{E}_c$ beyond its intersection with the reference plane $x'=0$. Similarly the secondary principal focus in the object space lies on the ray at a distance $-\mu\mathcal{E}_a$ from its intersection with the reference plane $x=0$, the measurement being made in the positive direction. By partial analogy with the properties associated with the nodal points of collinear imagery, if f is the object space secondary focal length, the y' and z' coordinates of the secondary image of the infinitely distant object (L, M, N) are Mf and Nf respectively. Equations (6) thus give $f=-\mu\mathcal{E}_b$, and similarly the image space secondary focal length is given by $f'=-\mu'\mathcal{E}_b$.

The secondary conjugate points corresponding to the magnification S must satisfy

$$\frac{Y'}{Y}=\frac{Z'}{Z}=s,$$

and if these points are distant ρ' and ρ from the corresponding principal foci, by equations (5) we have

$$\frac{\rho' M'-\mu M\mathcal{E}_b}{\rho M+\mu' M'\mathcal{E}_b}=\frac{\rho' N'-\mu N\mathcal{E}_b}{\rho N+\mu' N'\mathcal{E}_b}=s$$

or

$$\rho=-\frac{\mu\mathcal{E}_b}{s},\ \rho'=\mu'\mathcal{E}_b\cdot s$$

since for a skew ray M/M' and N/N' are not equal. The connection between the principal foci, the focal lengths, a pair of conjugate foci and the magnification for any ray thus correspond exactly to those found for the instrument as a whole in collinear imagery. The fact that this law is followed for lengths measured along the ray itself, and not their projections on the axis, clearly involves the failure of collinear imagery. The constant magnification surfaces in fact tend to be spherical rather than plane.

We will next determine the primary principal foci, which are the points of intersection of successive parallel incident rays lying in the same plane through the axis of the system. Without loss of generality we may suppose $z=z'=N=N'=0$, and the y' co-ordinate of the point in which the ray meets the plane $x'=X'$ is $\frac{M'}{L'}X'-\mu' M'\mathcal{E}_c-\mu M\mathcal{E}_b$. If this point is conjugate to the infinitely distant point (L, M), this value of y' will be unaltered by substituting $\left(L'-\frac{M'}{L'}\delta M',\ M'+\delta M'\right)$ for (L', M'). Since $\delta M'$ is finite, we see that we must travel along the ray from its intersection with the reference plane the distance

$$\frac{X'}{L'}=\mu' L'^2\{\mathcal{E}_c+2a\mathcal{E}_{bb}+2b\mathcal{E}_{bc}+2c\mathcal{E}_{cc}\}$$

to reach the primary principal focus. The corresponding distance for the object space is

$$-\mu L^2\{\mathcal{E}_a+2a\mathcal{E}_{aa}+2b\mathcal{E}_{ab}+2c\mathcal{E}_{bb}\}.$$

To determine the focal lengths we note from (5) that the ray $(M+\delta M, M')$ meets the reference plane in the point $y'+\delta y'$ where

$$\delta y'=-\mu\delta M\{\mathcal{E}_b+2a\mathcal{E}_{ab}+b(\mathcal{E}_{bb}+\mathcal{E}_{ac})+2c\mathcal{E}_{bc}\}.$$

Now the separation between these parallel emergent rays is $L'\delta y'$, and the angle between the two incident rays is $\delta M/L$. We define the focal length as the distance at which this separation is subtended by this angle, or

$$F=-\mu LL'\{\mathcal{E}_b+2a\mathcal{E}_{ab}+b(\mathcal{E}_{bb}+\mathcal{E}_{ac})+2c\mathcal{E}_{bc}\},$$

and similarly

$$F'=-\mu' LL'\{\mathcal{E}_b+2a\mathcal{E}_{ab}+b(\mathcal{E}_{bb}+\mathcal{E}_{ac})+2c\mathcal{E}_{bc}\},$$

where F and F' are the first and second primary focal lengths respectively. Substituting these values in generalised variations of (5) we find for points distant ρ and ρ' from the principal primary foci

$$L\delta Y-M\delta X=\rho\frac{\delta M}{L}-F'\frac{\delta M'}{L'},$$

$$L'\delta Y'-M'\delta X'=\rho'\frac{\delta M'}{L'}+F\frac{\delta M}{L},$$

showing that conjugate points for the transverse magnification p are given by $\rho=F/p$, $\rho'=-F'p$, in harmony with the laws found in other cases. Just as we extended the conception of secondary foci from skew rays to rays in an axial plane, we may extend the primary concept to rays in general by basing generalised definitions upon the expressions we have derived.

The Sine Law and the Cosine Law.—The conditions that must be satisfied for an instrument to yield a plane image of a plane object at the constant magnification G may now be investigated. Put

$$a=S^2A-SGB+G^2C,$$
$$b=2SA-(S+G)B+2GC,$$
$$c=A-B+C,$$

so that

$$(S-G)^2A=a-Gb+G^2c,$$
$$(S-G)^2B=2a-(S+G)b+2SGc,$$
$$(S-G)^2C=a-Sb+S^2c.$$

Adopting for the moment the ray conception of imagery,

$$y=\frac{\partial\mathcal{E}}{\mu\partial M}=\mu M\mathcal{E}_a+\mu' M'\mathcal{E}_b=$$

$$\frac{1}{(S-G)^2}\{(\mu M-G\mu' M')(\mathcal{E}_A+\mathcal{E}_B)+(\mu M-S\mu' M')(\mathcal{E}_B+\mathcal{E}_C)\}$$

$$y'=\frac{\partial\mathcal{E}}{\mu'\partial M'}=\frac{1}{(S-G)^2}\{(\mu M-G\mu' M')(G\mathcal{E}_A+S\mathcal{E}_B)$$
$$+(\mu M-S\mu' M)(G\mathcal{E}_B+S\mathcal{E}_C)\}$$

so that

$$y'-Gy=\frac{1}{S-G}\{(\mu M-G\mu'M')\mathcal{E}_B+(\mu M-S\mu'M')\mathcal{E}_C\}$$

and similarly

$$z'-Gz=\frac{1}{S-G}\{(\mu N-G\mu'N')\mathcal{E}_B+(\mu N-S\mu'N')\mathcal{E}_C\}$$

Thus, if the reference points lie in the planes conjugate to one another for magnification G, the presence of terms in B and C with finite coefficients involves displacements of the image points from their desired positions. The condition required is therefore that $\mathcal{E}$ should be a function of A only, that is the direction cosines only occur in the combination

$$(\mu M-G\mu'M')^2+(\mu N-G\mu'N')^2\,.$$

$\mu M-G\mu'M'$ and $\mu N-G\mu'N'$ must then be constant for all rays through a given object point. These are the generalised sine conditions. When the object point lies on the axis each of these quantities must vanish. In consequence of the axial symmetry only one condition, known as Abbe's sine condition, is in fact involved. If we write $G=\frac{l'}{l}$ where l and l' are conjugate lengths normal to the axis, and ψ and ψ' are the angles made by the ray with the axis, Abbe's condition takes the form $\mu l\sin\psi=\mu'l'\sin\psi'$, a result of which use has already been made in discussing the resolving power of optical instruments.

If $(0, y, z)$ is the point of intersection with the first reference plane of a ray A in the direction (L, M, N), and $(0, y+\delta y, z+\delta z)$ is the point in which a parallel ray B meets the same plane, the change of co-ordinates may be regarded as the result of a displacement through the distance σ in the direction l, m, n if $L\delta y=\sigma(Lm-Ml)$, $L\delta z=\sigma(Ln-Nl)$, which involve.

$$L(\delta y\delta M+\delta z\delta N)=\sigma L(l\delta L+m\delta M+n\delta N)-\sigma l(L\delta L+M\delta M+N\delta N)$$

whatever δL, δM, δN may be. If $(L+\delta L,\ M+\delta M,\ N+\delta N)$ is a neighbouring direction to (L, M, N) the equation becomes

$$\delta y\delta M+\delta z\delta N=\sigma(l\delta L+m\delta M+n\delta N).$$

Similarly if $(0, y', z')$, lies on ray A, and a parallel emergent ray C passes through $(0, y'+\delta y', z'+\delta z')$, and the displacement corresponds to a movement through the distance σ' in the direction (l', m', n'), we shall have

$$\delta y'\delta M'+\delta z'\delta N'=\sigma'(l'\delta L'+m'\delta M'+n'\delta N')$$

where $(L'+\delta L',\ M'+\delta M',\ N'+\delta N')$ is any direction near that of these two parallel rays. Now if the ray B emerges in the direction $(L'+\delta L',\ M'+\delta M',\ N'+\delta N')$ we have

$$\mu\delta y=\mu(y+\delta y-y)=\frac{\partial}{\partial M}(\mathcal{E}_{(B)}-\mathcal{E}_{(A)})=\mathcal{E}_{MM'}\delta M'+\mathcal{E}_{MN'}\delta N'+\cdots.$$

Similarly $\quad \mu\delta z=\mathcal{E}_{NM'}\delta M'+\mathcal{E}_{NN'}\delta N'+\cdots.$

Also if $(L+\delta L,\ M+\delta M,\ N+\delta N)$ is the direction of incidence of the ray C,

$$\mu'\delta y'=-\mathcal{E}_{MM'}\delta M-\mathcal{E}_{NM'}\delta N\cdots$$

$$\mu'\delta z'=-\mathcal{E}_{MN'}\delta M-\mathcal{E}_{NN'}\delta N\cdots$$

so that neglecting small quantities of the third order

$$\mu(\delta y\delta M+\delta z\delta N)+\mu'(\delta y'\delta M'+\delta z'\delta N')=0$$

or $\quad \mu\sigma(l\delta L+m\delta M+n\delta N)+\mu'\sigma'(l'\delta L'+m'\delta M'+n'\delta N')=0,$

that is $\quad \mu\sigma(\cos\theta_C-\cos\theta_B)+\mu'\sigma'(\cos\theta_B'-\cos\theta'_C)=0$

$$\mu\sigma\cos\theta_B-\mu'\sigma'\cos\theta_B'=\mu\sigma\cos\theta_C-\mu'\sigma'\cos\theta_C',$$

where θ and θ' are the angles made by the ray indicated with the directions (l, m, n) and (l', m', n') respectively. If then a small parallel displacement of a collection of incident rays, determined for example by their caustic surface, is to correspond to a parallel displacement of the emergent group, so that the caustic surface of the latter is to be translated without change of shape, the set of rays must all satisfy an equation of the form

$$\mu\cos\theta=p\mu'\cos\theta'+q$$

where p and q are constants, and the displacement in the image space will be p times as great as that in the object space. This cosine law is of wider application than the laws previously given, since no special assumptions, such as that the rays concerned all pass through a given point, have been made. The converse of this law, which has recently been extended in various directions, may also be proved. We can only consider here some specially simple applications.

The law of refraction is obtained by considering rays which pass through a point on the surface, the object and image displacements being necessarily equal. By considering a movement in the plane containing both rays we find, on writing ϕ and ϕ' for the complements of θ and θ', $\mu\sin\varphi=\mu'\sin\varphi'+q$, and q vanishes as φ and φ' vanish together. The analytical form may also be derived at once, for we must have

$$\mu(L\delta x+M\delta y+N\delta z)=\mu'(L'\delta x+M'\delta y+N'\delta z)+q,$$

where δx, δy, δz are the components of the common displacement, so long as $l\delta x+m\delta y+n\delta z=0$ where l, m, n are the direction cosines of the normal to the surface. That is to say $q=0$ and

$$\frac{\mu'L'-\mu L}{l}=\frac{\mu'M'-\mu M}{m}=\frac{\mu'N'-\mu N}{n}$$

is the formula required.

The Abbe Sine Law.—In a system symmetrical about an axis let there be no aberration in the image of a given point on the axis. The condition for the absence of aberrations in the image of a small object normal to the axis through this point is obtained by considering displacements normal to the axis. If ψ and ψ' are the angles made by an incident and the corresponding emergent ray with the axis, the condition is

$$\mu\sin\psi=p\mu'\sin\psi'+\text{constant}$$

where p is the transverse linear magnification. Since the axis itself is both an incident and emergent ray of the group forming the axial image, the constant is zero.

The Sine Law for Axial Displacements (Herschel's Condition).—In the previous system let displacements along the axis be considered. Then the condition that there should be no aberration in the image of a short element of length along the axis is

$$\mu\cos\psi=P\mu'\cos\psi'+\text{constant}.$$

Since $\psi=\psi'=0$ is a member of the group of rays, the constant is equal to $\mu-P\mu'$, and the condition may be written in the form

$$\mu^{\frac{1}{2}}\sin\tfrac{1}{2}\psi=P^{\frac{1}{2}}\mu'^{\frac{1}{2}}\sin\tfrac{1}{2}\psi'$$

which is inconsistent with the Abbe sine law unless $\psi=\pm\psi'$. Both conditions are satisfied by paraxial rays, and therefore $P=p^2\mu'/\mu$. This condition illustrates the proportionality of the longitudinal magnification to the square of the transverse magnification.

The Extended Sine Law.—If there is perfect imagery for the transverse plane for which the magnification is m, the displacement of the object and image point caustics must satisfy the cosine law for displacements in the directions of the y and z axes. Thus in the symmetrical system in which the axes of x and x' coincide with the axis of symmetry, and the axes of y and y' and of z and z' are respectively parallel to one another, the conditions for perfect imagery over the whole plane when there is no aberration on the axis are

$$\mu M-\mu'M'm=q$$

$$\mu N-\mu'N'm=q'$$

where q and q' are functions of y, z, the co-ordinates of the object point from which the rays arise. Symmetry shows that $q=yQ$, $q'=zQ$ where Q is a function of y^2+z^2.

The Construction of the Eikonal.—Before the expressions which have been derived can be applied the eikonal must be constructed. We proceed to show how this may be done.

Suppose that the surface whose homogeneous equation is

$f(a, x, y, z)=0$ separates media whose refractive indices are μ and μ' respectively. Let the reference planes for the two media both pass through the origin of co-ordinates and have direction cosines (L, M, N) and (L', M', N') respectively. Since for the stationary path the light travels perpendicularly to these planes, the distances of (x, y, z) from these planes for the light are $Lx+My+Nz$ and $L'x+M'y+N'z$ respectively. It readily follows that in the time taken by the light to travel from the plane (L, M, N) to the plane (L', M', N') via the point (x, y, z) the distance travelled in the standard medium is

$$\mathcal{E}=\mu(Lx+My+Nz)-\mu'(L'x+M'y+N'z).$$

If (x, y, z) determines the neighbourhood of the surface for which the time is stationary between the planes, we must have

$$(\mu L-\mu' L')\delta x+(\mu M-\mu' M')\delta y+(\mu N-\mu' N')\delta z=0$$

for all infinitesimal values of δx, δy, δz which satisfy

$$f_x\delta x+f_y\delta y+f_z\delta z=0.$$

That is to say we shall have

$$\frac{\mu L-\mu' L'}{f_x}=\frac{\mu M-\mu' M'}{f_y}=\frac{\mu N-\mu' N'}{f_z}$$

and each of these will be equal to

$$\frac{\mu(Lx+My+Nz)-\mu'(L'x+M'y+N'z)}{xf_x+yf_y+zf_z}.$$

Now, since f is homogeneous in a, x, y, z,

$$af_a+xf_x+yf_y+zf_z=0,$$

and therefore

$$\frac{\mathcal{E}}{af_a}=\frac{\mu' L'-\mu L}{f_x}=\frac{\mu' M'-\mu M}{f_y}=\frac{\mu' N'-\mu N}{f_z}$$

Now f_a, f_x, f_y, f_z are four homogeneous functions of a, x, y, z, between which the three ratios of these variables may be eliminated, giving

$$\phi(f_a,\ f_x,\ f_y,\ f_z)=0$$

where ϕ is a homogeneous function. It at once follows that $\mathcal{E}$ satisfies the equation

$$\phi(\mathcal{E}/a,\ \mathcal{L},\ \mathcal{M},\ \mathcal{N})=0$$

where $\mathcal{L}, \mathcal{M}, \mathcal{N}$ denote $\mu' L'-\mu L$, $\mu' M'-\mu M$, $\mu' N'-\mu N$ respectively. This equation expresses $\mathcal{E}$, the stationary path length between the planes (L, M, N) and (L', M', N'), in terms of their direction cosines, so that $\mathcal{E}$ is the eikonal.

Consider refraction at the paraboloid of revolution

$$y^2+z^2-4ax=0.$$

Here

$$\frac{f_a}{-4x}=\frac{f_x}{-4a}=\frac{f_y}{2y}=\frac{f_z}{2z},$$

so that

$$f_y^2+f_z^2-f_af_x=0$$

and
$$\mathcal{E}=a\,\frac{\mathcal{M}^2+\mathcal{N}^2}{\mathcal{L}}.$$

Again at the spherical surface

$$x^2+y^2+z^2-r^2=0$$

we have
$$\frac{f_x}{x}=\frac{f_y}{y}=\frac{f_z}{z}=\frac{f_r}{-r},$$

and therefore
$$f_x^2+f_y^2+f_z^2=f_r^2$$

or
$$\mathcal{E}=\pm r(\mathcal{L}^2+\mathcal{M}^2+\mathcal{N}^2)^{\frac{1}{2}}.$$

One root corresponds to the part of the surface which is convex, the other to the part which is concave, to the incident light.

By a similar process the equation of the refracting surface may be found when $\mathcal{E}$ is given as a homogeneous function of the first order in $\mathcal{L}, \mathcal{M}, \mathcal{N}$. The equation of the eikonal for the sphere may be written

$$\mathcal{E}=r[\mu'^2+\mu^2-2b-2(\mu^2-2a)^{\frac{1}{2}}(\mu'^2-2C)^{\frac{1}{2}}]^{\frac{1}{2}}=r(\mu'\cos\phi'-\mu\cos\phi)$$

where ϕ and ϕ' are the angles of incidence and refraction. If then we write $\kappa=\dfrac{\mu'\cos\phi'-\mu\cos\phi}{r}$, we have $\mathcal{E}=r^2\kappa$, $\mathcal{E}\mathcal{E}_b=-r^2$ or the secondary focal lengths are μ/κ and μ'/κ respectively, where κ is called the secondary power. The equations

$$\kappa\mathcal{E}_a=\frac{\mu' L'}{\mu L},\ \kappa\mathcal{E}_c=\frac{\mu L}{\mu' L'}$$

merely mean that the refracting surface is the unit surface. Again

$$\mathcal{E}_b+2a\mathcal{E}_{ab}+b\mathcal{E}_{bb}+b\mathcal{E}_{ac}+2c\mathcal{E}_{bc}=-\frac{\cos\phi\cos\phi'}{LL'\kappa}$$

so that the primary power is $\kappa\sec\phi\sec\phi'$; also

$$\mathcal{E}_c-L'^2\{\mathcal{E}_c+2a\mathcal{E}_{bb}+2b\mathcal{E}_{bc}+2c\mathcal{E}_{cc}\}=\frac{\sin^2\phi}{\kappa},$$

the quantity on the left when multiplied by μ' being the distance between the primary and secondary principal foci in the image space, that is to say the astigmatism. It is worth noting that at the two principal foci the astigmatism is inversely as the refractive index.

When the incidence is normal both powers become equal to $\dfrac{\mu'-\mu}{r}$, an expression of importance because in a symmetrical instrument incidence is normal for paraxial rays, that is rays which lie close to the axis of symmetry. As the unit in which powers are expressed, the dioptrie or dioptre, the inverse of a metre, is universally employed. Thus a lens of power 5 dioptries (written 5D.) has a focal length of 20 cm. in air.

The Combination of Systems.—Having found the eikonal for the separate surfaces of the instrument it is now necessary to find those for the combination. The process involved may be illustrated by combining two systems. Let O_0, O_1 and O_2 in media of refractive indices μ_0, μ_1 and μ_2 be the reference points on the axis, $\mathcal{E}_1$ the eikonal for the first portion between planes through O_0 and O_1, $\mathcal{E}_2$ that for the second part between planes through O_1 and O_2, and $\mathcal{E}_{12}$ that for the whole. From the definitions of the eikonal it follows that $\mathcal{E}_{12}=\mathcal{E}_1+\mathcal{E}_2$. Moreover

$$-\frac{\partial\mathcal{E}_1}{\partial M_1}=\mu_1 y_1=\frac{\partial\mathcal{E}_2}{\partial M_1},\ \text{or}\ \frac{\partial}{\partial M_1}(\mathcal{E}_1+\mathcal{E}_2)=0$$

with a similar equation involving N_1. These two conditions enable M_1 and N_1 to be eliminated from $\mathcal{E}_1+\mathcal{E}_2$, leaving $\mathcal{E}_{12}$ expressed in terms of the external variables only.

Paraxial Laws.—From the formulae reached in a previous section we see that the refraction of paraxial rays is determined by the part of $\mathcal{E}$ which is linear in a, b and c. Let us put

$$\mathcal{E}=\text{const.}+\alpha a+\beta b+\gamma c+\cdots;$$

then the conditions from which M_1 and N_1 are to be found are

$$\mu_0 M_0\beta_1+\mu_1 M_1\gamma_1+\mu_1 M_1\alpha_2+\mu_2 M_2\beta_2=0,$$
$$\mu_0 N_0\beta_1+\mu_1 N_1\gamma_1+\mu_1 N_1\alpha_2+\mu_2 N_2\beta_2=0.$$

Squaring and adding we find for the combination

$$\mathcal{E}=\text{constant}+\alpha_1 a-\frac{\beta_1^2 a+\beta_1\beta_2 b+\beta_2^2 c}{\gamma_1+\alpha_2}+\gamma_2 c+\cdots.$$

This expression shows that it we put

$$\alpha=\frac{A}{B},\ \beta=-\frac{1}{B},\ \gamma=\frac{C}{B},\ AC-BD=1$$

the paraxial constants of the compound instrument are given by the matrix law

$$\begin{pmatrix}A_{12} & D_{12}\\ B_{12} & C_{12}\end{pmatrix}=\begin{pmatrix}A_1 & D_1\\ B_1 & C_1\end{pmatrix}\begin{pmatrix}A_2 & D_2\\ B_2 & C_2\end{pmatrix},$$

the extension of which to any number of systems is simple. It is an easy matter to show that the equations for the points in which a ray meets the reference planes are given by

$$\begin{pmatrix}A & 1\\ 1 & C\end{pmatrix}\begin{pmatrix}\mu M & \mu N\\ -\mu' M' & -\mu' N'\end{pmatrix}=B\begin{pmatrix}y & z\\ y' & z'\end{pmatrix},$$

the converse relation by

$$\begin{pmatrix} A & 1 \\ 1 & C \end{pmatrix}\begin{pmatrix} -y' & -z' \\ y & z \end{pmatrix} = D\begin{pmatrix} \mu' M' & \mu' N' \\ \mu M & \mu N \end{pmatrix},$$

and the relation between axial conjugate points by

$$(\mu \quad x)\begin{pmatrix} A & D \\ B & C \end{pmatrix}\begin{pmatrix} x' \\ -\mu' \end{pmatrix} = 0.$$

If the system consists of a series of spherical refracting surfaces of powers $\kappa_1, \kappa_2, \kappa_3, \cdots$ and separations $\mu_1\tau_1, \mu_2\tau_2, \cdots$ between their vertices, the constants are calculated from the product

$$\begin{pmatrix} A & D \\ B & C \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ \kappa_1 & 1 \end{pmatrix}\begin{pmatrix} 1 & -\tau_1 \\ 0 & 1 \end{pmatrix}\begin{pmatrix} 1 & 0 \\ \kappa_2 & 1 \end{pmatrix}\begin{pmatrix} 1 & -\tau_2 \\ 0 & 1 \end{pmatrix}\begin{pmatrix} 1 & 0 \\ \kappa_3 & 1 \end{pmatrix} \cdots$$

where the reference points are at the points of intersection of the axis with the extreme surfaces and, for any surface separating media of refractive indices μ and μ', $\kappa = R(\mu' - \mu)$, R being the curvature of the surface at the vertex, considered positive if its convex side is presented to the incident light. In the special case in which all the refracting surfaces cross the axis at the same point this product reduces to the simple form

$$\begin{pmatrix} A & D \\ B & C \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ \kappa_1 + \kappa_2 + \kappa_3 + \cdots & 1 \end{pmatrix}.$$

Systems in which the overall axial depth is negligible are termed "thin." They are of much importance in the preliminary development of instruments owing to the simplicity of all formulae relating to thin systems and to the accident that it is nearly always the aim of the designer of optical systems to use no greater amount of glass, quartz or other transparent solid than is necessary.

Chromatic Aberrations.—We have hitherto regarded the refractive index as a property of the medium only. Optical instruments in general are used for the control of light of various wave-lengths, and as the nature of the light is changed the refractive index of the medium alters. It follows that A, B, C, D are liable to vary as the colour of the light changes and the position and size of the image of a given object likewise vary. Most instruments would not be of much value unless these variations could be reduced to very small amounts. We will determine the conditions that must be satisfied for them to be eliminated. We shall assume that the two media external to the system are alike and are the standard medium to which the value unity for the refractive index is conventionally ascribed for all wave-lengths.

The matrix for refraction at a single surface is

$$\begin{pmatrix} 1 & 0 \\ R(\mu' - \mu) & 1 \end{pmatrix},$$

and this may be replaced by the product

$$\begin{pmatrix} 1 & 0 \\ R(1 - \mu) & 1 \end{pmatrix}\begin{pmatrix} 1 & 0 \\ R(\mu' - 1) & 1 \end{pmatrix}$$

corresponding to refraction from the medium of index μ into the standard medium followed immediately by refraction from the standard medium into that of index μ'. We may therefore consider the system as a combination of a series of bodies, each bounded by two refracting surfaces, immersed in the standard medium. We call each of these elementary bodies a simple lens, and it is convenient to regard such lenses rather than the separate surfaces as the elements from which the instrument is built. The matrix for the instrument now takes the form

$$\begin{pmatrix} A & D \\ B & C \end{pmatrix} = \begin{pmatrix} A_1 & D_1 \\ B_1 & C_1 \end{pmatrix}\begin{pmatrix} 1 & -s_1 \\ 0 & 1 \end{pmatrix}\begin{pmatrix} A_2 & D_2 \\ B_2 & C_2 \end{pmatrix}\begin{pmatrix} 1 & -s_2 \\ 0 & 1 \end{pmatrix} \cdots$$

where s_1, s_2 are separations in the standard medium between the vertices of successive lenses, and thus do not vary as the constitution of the light changes. If in consequence of a change in the wave-length of the light the matrix for a typical lens becomes

$$\begin{pmatrix} A + \delta A & D + \delta D \\ B + \delta B & C + \delta C \end{pmatrix},$$

the changes in the coefficients for the entire instrument to a first approximation will be given by

$$\begin{pmatrix} \delta A & \delta D \\ \delta B & \delta C \end{pmatrix} = \sum (P)\begin{pmatrix} \delta A_k & \delta D_k \\ \delta B_k & \delta C_k \end{pmatrix}(P')$$

where (P) and (P') denote the products of the matrices respectively preceding and following those of the lens κ in the matrix product for the entire system, and the summation extends to all the lenses.

Now
$$\begin{pmatrix} A & D \\ B & C \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ \dfrac{C-1}{D} & 1 \end{pmatrix}\begin{pmatrix} 1 & D \\ 0 & 1 \end{pmatrix}\begin{pmatrix} 1 & 0 \\ \dfrac{A-1}{D} & 1 \end{pmatrix},$$

and thus $\dfrac{C-1}{D} = R(\mu - 1)$, $\dfrac{A-1}{D} = R'(1-\mu)$, $D = -t/\mu$ where R, R', t are the curvatures of the two surfaces and the axial thickness of the single lens. It follows that for light of a different colour for which the refractive index is $\mu + (\mu - 1)/\nu$, where ν is a quantity regularly given by glass makers, the increments in A, C, D are given to the first order by

$$\delta\frac{A-1}{D} = \frac{A-1}{D\nu},\ \delta\frac{C-1}{D} = \frac{C-1}{D\nu},\ \delta D = -D\frac{\mu-1}{\mu\nu},$$

so that $\delta A = \dfrac{A-1}{\mu\nu}$, $\delta C = \dfrac{C-1}{\mu\nu}$, $\delta B = \dfrac{B}{\nu} + \dfrac{(A-1)\,(C-1)}{\mu\nu D}$,

that is to say the increment in the matrix is

$$\frac{1}{\nu}\begin{pmatrix} 0 & -D \\ B & 0 \end{pmatrix} + \frac{1}{\mu\nu}\begin{pmatrix} A-1 & D \\ \dfrac{(A-1)(C-1)}{D} & C-1 \end{pmatrix}.$$

When the thickness of the component is negligible only the first of these matrices is of consequence, and the only alteration is due to a proportional change in B. If all the components are thin lenses in contact, the properties of the system, so far as the paraxial terms are concerned, will be the same for light of the two wave-lengths if $\Sigma\dfrac{B}{\nu} = 0$. In particular for a system of two thin lenses in contact we have

$$\frac{B_1}{\nu_1} = -\frac{B_2}{\nu_2} = \frac{B_{12}}{\nu_1 - \nu_2}$$

as the sole condition for achromatism. In the more general case the expressions most frequently employed are that given for δB and

$$\delta\left(\frac{A}{B}\right) = -\frac{1}{\nu}\left\{\frac{A}{B} - \frac{(A-1)^2}{\mu D B^2}\right\},\ \delta\left(\frac{C}{B}\right) = -\frac{1}{\nu}\left\{\frac{C}{B} - \frac{(C-1)^2}{\mu D B^2}\right\}.$$

Alternatively we may divide the complete expression into the three parts

$$\frac{1}{\nu}\begin{pmatrix} 0 & -D \\ B & 0 \end{pmatrix} + \frac{1}{\mu\nu}\begin{pmatrix} A & D \\ B & C \end{pmatrix} - \frac{1}{\mu\nu}\begin{pmatrix} 1 & 0 \\ \dfrac{A+C-2}{D} & 1 \end{pmatrix}$$

where the first indicates a proportional increment in the power of the element and a decrement in its effective thickness, the second a proportional change in all constants of the complete system, and the last the subtraction of the change in these constants which would arise if the separation between the surfaces of the component were annihilated without any change in the curvatures of its surfaces. In actual calculations it is probably more convenient to replace the $-D$ in the first part by 0 and the 0 in the last part by $-t$.

In a large number of instruments having a small field of view the only condition to which close attention is paid is the coincidence of the principal focal planes for different colours corresponding to $\delta\left(\dfrac{C}{B}\right) = 0$. When the field is large the condition $\delta B = 0$ has to be closely satisfied also. In the older eyepieces consisting of two separated simple thin lenses (those nearest the objective and the eye being respectively named the field lens and the eye lens), no other chromatic condition was imposed on this part of the instrument. This leads to the definite value

$$\left(\frac{\nu_1}{\kappa_1} + \frac{\nu_2}{\kappa_2}\right) \Big/ (\nu_1 + \nu_2)$$

for the axial separation of the two lenses, and when both lenses are made from the same kind of glass the old rule that the separation should equal the mean of the focal lengths of the two lenses follows. Modern eyepieces have to cover larger fields than are suited to the older forms, and either the field lens, or the eye lens, or both are compound. Attention to all three conditions is comparatively rare, and is only of importance when good correction is desired in widely separated image planes. If the system is symmetrical end for end, $A=C$, and the three conditions fall to two. Since

$$\begin{pmatrix} A & D \\ B & C \end{pmatrix}\begin{pmatrix} C & \frac{D}{p} \\ pB & A \end{pmatrix}=\begin{pmatrix} AC+pBD & \left(1+\frac{1}{p}\right)AD \\ (1+p)BC & AC+\frac{1}{p}BD \end{pmatrix},$$

a complete system made from two similar components, not necessarily of equal focal length, with corresponding parts next to one another, will be achromatised if A/B and D/C remain unaltered as the colour changes, that is to say the separate components, must be corrected for the position in which light parallel to the axis between the components comes to a focus, and for the image of the centre of symmetry.

The discussion of the conditions which should be satisfied when the rays considered do not lie close to the axis does not differ in any essential feature from that just given.

Aberrations for Homogeneous Radiation.—We have seen earlier that a plane image of a plane object will only be secured when $\mathcal{E}$ is expressible as a function of $(\mu M-G\mu' M')$ and $(\mu N-G\mu' N')$ only, where G is the transverse magnification. In general other terms occur, and the characteristic effects due to them are called aberrations. The quadratic terms in $\mathcal{E}$ may be written in the form

$$-\tfrac{1}{2}\left[\sigma_0 A^2-2\sigma_1 AB+\sigma_2 B^2+2\left(\sigma_2+\frac{\omega}{\kappa}\right)AC-2\sigma_3 BC+\sigma_4 C^2\right]$$

where A, B, C denote the quantities previously defined and the σ's are known as the aberrational coefficients; σ_1 is the coefficient for distortion, σ_2 for astigmatism, ω for curvature of the field, σ_3 for coma, and σ_4 for central aberration. Central aberration is so named because the other aberrations disappear on the axis of the system. It must not be supposed that central aberration is not present over the whole field. The significance of these terms will be more fully appreciated if we note that the co-ordinates (Y, Z) of an image point when aberrations are absent are given by

$$Y\kappa=\mu M-G\mu' M',\ Z\kappa=\mu N-G\mu' N'.$$

If then (η, ζ) is the point in which the plane of the stop is met we may substitute

$$A=\frac{(Y^2+Z^2)\kappa^2}{2(S-G)^2},\ B=\frac{(Y\eta+Z\zeta)\kappa^2}{(S-G)^2},\ C=\frac{(\eta^2+\zeta^2)\kappa^2}{2(S-G)^2}$$

in either the expression for $\mathcal{E}$ or in

$$y'-Y=\frac{1}{(S-G)}(Y\mathcal{E}_B+\eta\mathcal{E}_C),\ z'-Z=\frac{1}{S-G}(Z\mathcal{E}_B+\zeta\mathcal{E}_C).$$

From the latter we see that a finite value of σ_1 implies only a fixed displacement of the image point from its ideal position, so that object and image are not geometrically similar; hence the description of this aberration as distortion. At the displaced image point there is no difference of phase. By writing

$$(Y^2+Z^2)(\eta^2+\zeta^2)=(Y\eta+Z\zeta)^2+(Y\zeta-Z\eta)^2$$

we see that the terms in B^2 and AC may be analysed into two components, for one of which the point of intersection with the stop lies in the same axial plane as the object point, and for the other in a perpendicular axial plane. It is easy to show that either of these divergences may be removed for a given object point by moving the image plane along the axis. The terms in fact denote that the primary and secondary image surfaces are curved, the curvatures at the axis being $3\kappa^2\sigma_2+\kappa\omega$ and $\kappa^2\sigma_2+\kappa\omega$ respectively. The common part $\kappa\omega$, which depends only on the Airy-Petzval sum, is known technically as the curvature. A finite value of σ_2 implies that the primary and secondary image surfaces differ in curvature, so that σ_2 measures their separation, *i.e.*, the astigmatism. The coma, which has σ_3 for its coefficient, differs from the others in that $y'-Y$ and $z'-Z$ change in sign with η and ζ. The geometrical trace of the rays is therefore unsymmetrical and the phase variation is also unsymmetrical. No change of focus will remove this defect, but the want of symmetry may be removed, for small apertures, by choosing a proper position for the stop. Such a change however also affects the aberrations we have already mentioned. It may easily be shown that the rays from any object point which pass through one half of a circular zone of the stop concentric with the axis, meet the image plane in a complete circle, touching two straight lines, making an angle of 60° with one another, which meet in the image point for light which has passed through the centre of the stop. The primary focus for rays in the axial plane is three times as far as the secondary focus from the ideal image point. The central aberration measured by σ_4 is symmetrical, the rays through concentric circular zones of the stop meeting the image surface in concentric circular zones of radii proportional to the cube of the radii of the former. The aberration implies that each zone has a separate surface on which the image is formed, owing to want of agreement of phase. The primary foci for light from a point on the axis lie on a semi-cubical paraboloid with the axis of the system for its axis of revolution; the axis itself is the locus of the secondary foci. The former are three times as far as the latter from the paraxial image plane. The coefficient σ_0, with a correction added, is the quantity which corresponds to σ_4 when the reference plane is moved to another position. It is interpreted as the central aberration at the middle of the stop.

We can obtain the addition laws very simply for these aberrations by noting that, since all the paraxial terms when eikonals are added are completely accounted for by substituting for the intermediate direction cosines expressions linear in the external direction cosines, we have only to make the same substitutions for A, B, C in these aberrational terms. The expressions obtained in this way are

$$(\sigma_p)_{1,n}=\Sigma(\sigma_p)_\kappa S_\kappa^{4-p} G_\kappa^p,\ (p=0, 1, 2, 3, 4),$$

where the component parts are n in number, of which κ is a typical member, and S_κ, G_κ are the magnifications which the images of the stop and of the object formed by lens κ undergo in the subsequent parts of the system. The quantity $\frac{\omega}{\kappa}$, where κ is the power of the system, is transformed according to the same law as σ_2, and in this case we are led to an expression which is well known on account of its simplicity. This is the so-called Petzval sum

$$(\omega\kappa)_{1,n}=\Sigma(\omega\kappa)_\kappa$$

where $\omega_\kappa=\frac{1}{\mu_\kappa\mu'_\kappa}$. A more correct name would be the Airy sum, using the name of its first discoverer.

If $\mathcal{E}$ and $\mathcal{E}'$ are the eikonals for the same system when the reference points correspond to two different magnifications G and G', we have

$$\mathcal{E}-\frac{\mu^2 L}{\kappa G}-\frac{\mu'^2 L' G}{\kappa}=\mathcal{E}'-\frac{\mu^2 L}{\kappa G'}-\frac{\mu'^2 L' G'}{\kappa},$$

and if A', B', C' are the effective variables in the latter expression corresponding to the A, B, C of the former, we obtain a linear transformation from the one system to the other, and the aberrational coefficients for any positions of the object and stop can be expressed in terms of those for standard positions. By paying special attention to the factor $4AC-B^2$ which can be separated in a large number of terms, we are enabled to classify the aberrations generally by order and by series, the latter classification deriving its importance from the fact that though the conditions for the disappearance of any given aberration depend on the magnification, the disappearance of all the aberrations of a given order and series for a given pair of object and stop positions involves their disappearance for all positions. To this rule there is only one exception—that of the zero series, comprised of terms

which do not contain $4AC-B^2$ as a factor. In the quadratic terms just considered we may write the terms in B^2 and AC in the form

$$-\frac{1}{6}\left(3\sigma_2+\frac{\omega}{\kappa}\right)(B^2+2AC)-\frac{\omega}{6\kappa}(4AC-B^2)$$

showing that the term involving ω belongs to series 1.

It is no less advantageous when considering aberrations than when dealing with the paraxial constants to take the simple lens rather than the single surface as the effective unit. We proceed to find expressions for the aberrational coefficients of a simple thin lens, taking as the standard conditions the stop in the unit surface and the object in the surface for magnification -1. This choice offers many advantages due to symmetry. If object and image space are interchanged the coefficients with an even suffix are unaltered and those with an odd suffix merely changed in sign.

If the origins are taken at the vertex of a single surface system of power κ_1,

$$\mathcal{E}_1=\frac{\mu_1-\mu_0}{2\kappa_1}\left[\frac{\mathcal{M}_1^2+\mathcal{N}_1^2}{\mathcal{L}_1}-\frac{\epsilon_1(\mathcal{M}_1^2+\mathcal{N}_1^2)^2}{2\mathcal{L}_1^3}+\cdots\right].$$

Adding a similar expression, the condition, $\dfrac{\partial}{\partial M_1}(\mathcal{E}_1+\mathcal{E}_2)=0$ gives $\mu_1M_1\kappa=\mu_0M_0\kappa_2+\mu_2M_2\kappa_1$, where $\kappa=\kappa_1+\kappa_2$.

Hence $$\mu_1M_1=\frac{\mu_0M_0+\mu_2M_2}{2}-\frac{\kappa_1-\kappa_2}{\kappa}\left(\frac{\mu_0M_0-\mu_2M_2}{2}\right),$$

$$\frac{\mathcal{M}_1}{\kappa_1}=\frac{\mathcal{M}_2}{\kappa_2}=-\frac{\mu_0M_0-\mu_2M_2}{\kappa}.$$

To secure reference points at the negative unit surfaces we have to add $2(\mu_2^2L_2+\mu_0^2L_0)/\kappa$ to $\mathcal{E}$. Write 1, μ, 1 for μ_0, μ_1, μ_2 and put $\kappa_1-\kappa_2=2(\mu-1)\rho\kappa$ so that $\rho\kappa$ is the common addition made to the curvature of both surfaces to derive its shape from the symmetrical form. Then on expansion we find

$$\begin{aligned}\mathcal{E}\kappa &=4-4A-2A^2-2B^2-4(1+\omega)AC-8\rho(1+\omega)BC\\ &-2\left[\frac{1}{(1-\omega)^2}+4\rho^2(1+2\omega)+(\epsilon_1+\epsilon_2-1)\left\{\frac{1}{(\mu-1)^2}+12\rho^2\right\}\right.\\ &\left.\qquad+(\epsilon_1-\epsilon_2)2\rho\left\{\frac{3}{\mu-1}+4\rho^2(\mu-1)\right\}\right]C^2+\cdots\end{aligned}$$

where $\omega=1/\mu$. If the surfaces are spherical $\epsilon_1=\epsilon_2=\frac{1}{2}$ and the last two terms disappear from the coefficient of C^2. If they are paraboloidal $\epsilon_1=\epsilon_2=0$ and the coefficient of C^2 becomes

$$-2\left[\frac{1+\omega}{1-\omega}-8\rho^2(1-\omega)\right].$$

Since the refracting surfaces are in contact the coefficient of A^2 must correspond to the absence of stop aberration. The absence of a term in AB indicates that there is no distortion. The coefficients which determine the curvature and astigmatism are not under control. The coma may be removed by giving the lens a symmetrical form—that is by making $\rho=0$. The central aberration can then only be controlled by giving the surfaces a suitable shape—viz., by making $\epsilon_1=\epsilon_2=-\frac{1}{2}(\mu^2-1)$. This fixes the eccentricity of the osculating ellipsoids.

Let us write 4β for the coefficient BC and -2γ for that of C^2. Then with the stop magnification S and the object magnification G, after moving the origins and introducing the appropriate changes in A, B, C, we find the following expression, most of the coefficients in which were first obtained by Airy.

$$\begin{aligned}\mathcal{E}\kappa=&-\frac{(1-G)^2}{G}+\frac{(S-G)^2}{G}A-\frac{(S-G)(S^3-G)}{2G}A^2\cdots\\ &-\tfrac{1}{8}[\gamma-4\mathcal{S}\beta+\mathcal{S}^2(3+2\omega)](1-S)^4A^2\\ &+\tfrac{1}{4}[\gamma-(3\mathcal{S}+\mathcal{G})\beta+3\mathcal{S}^2+\mathcal{S}(\mathcal{S}+\mathcal{G})\omega](1-S)^3(1-G)AB\\ &-\tfrac{1}{8}[\gamma-2(\mathcal{S}+\mathcal{G})\beta+\mathcal{S}(\mathcal{S}+2\mathcal{G})\\ &+\tfrac{1}{3}(\mathcal{S}^2+4\mathcal{S}\mathcal{G}+\mathcal{G}^2)\omega](1-S)^2(1-G)^2(2AC+B^2)\\ &-\frac{\omega}{12}(S-G)^2(4AC-B^2)\\ &+\tfrac{1}{4}[\gamma-(\mathcal{S}+3\mathcal{G})\beta+\mathcal{G}(2\mathcal{S}+\mathcal{G})+\mathcal{G}(\mathcal{S}+\mathcal{G})\omega](1-S)(1-G)^3BC\\ &-\tfrac{1}{8}[\gamma-4\mathcal{G}\beta+\mathcal{G}^2(3+2\omega)](1-G)^4C^2\end{aligned}$$

where $\mathcal{S}=\dfrac{1+S}{1-S}$, $\mathcal{G}=\dfrac{1+G}{1-G}$ and the terms in the first line correspond to the elimination of aberrations. We may now employ the addition formulae for these aberrational coefficients to obtain corresponding expressions for any number of thin lenses in contact. We then find that ω is the Airy-Petzval sum, and if $\rho\kappa$ is a common curvature addition made to all the surfaces from a standard form the preceding formulae apply without alteration except that β and γ take the forms

$$\beta=\beta_0+2\rho(1+\omega),\quad \gamma=\gamma_0+4\rho^2(1+2\omega).$$

These formulae are particularly advantageous in their application to lenses which are to be cemented together, so that the second surface of one lens has the same curvature as the first surface of the next succeeding lens. For example telescope objectives may be advantageously designed in this way, the conditions to be applied being $\sigma_3=\sigma_4=0$, that is $\beta=(2+\omega)\mathcal{G}$, $\gamma=(5+2\omega)\mathcal{G}^2$, where $\mathcal{G}=1$ for an infinitely distant object. The coma is eliminated by giving a suitable degree of "bending" to the lens as a whole, and the central aberration by the choice of suitable glasses, or by departing from the spherical form for the surfaces, or by distributing the lens powers suitably between three or more components. When there are only two component lenses the ratio of their powers is determined by the condition for the removal of the chromatic aberrations. For more complete information on these developments the reader is referred to numerous papers in the *Transactions of the Optical Society*.

When the lens is no longer thin expressions for the aberrations differing very slightly from those just given may be obtained by the same general procedure. As a rule it is unnecessary to repeat the calculations after such thicknesses as are necessary for the construction of an actual lens have been introduced, as it has been shown that over a wide range of constructions the aberrations of this order introduced by separating the surfaces are automatically compensated in the most advantageous way by the aberrations of the next higher order which become significant at the aperture the thickness is introduced to yield.

Formulae may be obtained for these higher order aberrations in a similar manner; the chief complication is due to the necessity for taking into account in the values of M_1 and N_1 terms depending on the lower order aberrations.

Main Types of Optical Instruments.—Optical instruments tend to assume one of a few forms. Telescopes are systems of very great or even infinite focal length; they may invariably be regarded as a combination of two systems of finite focal length placed with their inner principal focal surfaces nearly or exactly in coincidence. The one part, often of large absolute aperture and long focal length, usually conforms to the thin lens type and is corrected for coma and central aberration. In the other part, the eyepiece, attention is chiefly given to the curvature and astigmatism. Telescopes are essentially instruments for increasing the angle an object appears to subtend at an observer's eye, and in most of them the field of view is small. At the opposite extreme are microscopes, also divisible into objective and eyepiece, but the former is of short focal length and small absolute, but large numerical, aperture. In the higher powers (that is shorter focal lengths) the objectives tend to be very complex. As with telescopes the most important objective corrections are those for colour, central aberration and coma. The eyepiece is of simple construction. Only a small part of an object can be viewed at once. Camera lenses form a class in some respects intermediate between telescopes and microscopes. The field is large and the numerical aperture moderate. In general they are not separable into parts having distinct functions, and all aberrations must be considered. The use of lenses at appreciable axial separations is necessary for the attainment of satisfactory

corrections.

Ray Tracing.—The professional optical designer in evolving complex instruments finds it expedient to use formulae for the aberrational coefficients merely as a general qualitative or roughly quantitative guide to indicate the modifications he should make in a partially developed system to reduce as far as possible the remaining aberrations. The outstanding difficulty in the way of using algebraic expansions for the whole of his work is the uncertain value of the terms of the expansion he must neglect. As he aims at taking into consideration lengths as small as a quarter of a wave length or less, that is to say about one ten-thousandth of a millimetre, it will be appreciated that our knowledge of the higher order aberrations must be thorough before reliance can in general be placed on expansions. The method adopted by the designer is to trace step by step through the system a selected set of rays, and to infer from their positions in the image space the aberrations remaining in the system. For tracing these rays many methods have been devised, of which particulars may be obtained from practical treatises. They are usually entirely trigonometrical, and logarithmic tables are generally employed. The calculations for skew rays are necessarily much more troublesome than those for rays in an axial plane, and in practice skew rays are rarely computed. A method of computing rays in an axial plane, suitable for use with a calculating machine, is as follows.

The incident ray is defined by $\flat$, the length of the perpendicular to the ray from the vertex of the surface, and $\sin\psi$, where ψ is the angle between the ray and the axis. The refractive index is denoted by μ, the angle of incidence by ϕ, the curvature of the surface by R, and the separation between the vertices of this and the next surface by t. The same letters, with accents where necessary, are used for the refracted ray, and with the suffix 1 for the following surface.

In the customary methods of calculation ψ_1 is found by the angular relation

$$\psi_1=\psi'=\psi-\phi+\phi'$$

which necessitates references to tables. In the present method the use of these tables is avoided by first finding an approximate value $\sin\theta$ for $\sin\psi'$ given by

$$\sin\theta=\sin\psi-\sin\phi+\sin\phi'.$$

In the absence of aberration this value is correct, and also $\flat'=\flat$. In general aberration is present and corrections of aberrational magnitude are required. The working equations are

$$\begin{aligned}
\sin\phi&=\sin\psi+R\flat,\\
\sin\phi'&=\sin\phi\times\mu/\mu,\\
\sin\theta&=\sin\psi-\sin\phi+\sin\phi',\\
N&=\flat\,(\sin\phi-\sin\phi')\,(\sin\psi+\sin\phi'),\\
D&=\tfrac{1}{4}\{\sin^2\theta+(\cos\psi+\cos\phi+\cos\psi')^2-1\},\\
\flat'-\flat&=N/D,\\
\sin\psi'&=\sin\theta-R(\flat'-\flat),\\
\flat_1&=\flat'+t\sin\psi_1.
\end{aligned}$$

It is to be noted that $\frac{1}{2}N$ and $\frac{1}{2}N\mu\sin\phi$ are the linear first order coma and spherical aberration respectively for the single refraction, D is the ratio of twice the first order aberration to the total aberration, and

$$\frac{(\flat'-\flat)\mu\sin\phi}{\{(1+\cos\psi)\,(1+\cos\phi)\,(1+\cos\phi')\,(1+\cos\psi')\}^{\frac{1}{2}}},$$

which is represented at most refractions with ample accuracy by

$$\tfrac{1}{4}(\flat'-\flat)\mu\sin\phi,$$

is the difference in path between the route along the ray and that along the axis from their first to their second crossing point. Brief tables are used for finding D.

Graphical methods of representing the state of correction of the system are widely used. For example the central aberrations may be shown by taking as ordinate the distance from the axis at which a ray crosses the unit surface and as abscissa the distance of its intersection with the axis from a suitable fixed point. The type of curve thus secured is widely used. The paraxial portion of the curve touches the ordinate axis. A more useful curve is obtained by taking the square of the height at which the unit surface is crossed as ordinate. The inclination of this curve to the ordinate axis for rays near the axis depends on the lowest order central aberration, and the curvature gives higher order aberrations. Moreover if we draw through any point X on the abscissa axis a straight line parallel to the ordinate axis, the areas intercepted between this line and the curve measure the differences of path for light passing through the corresponding zones of the unit surface when the image point is at X. By choosing this ordinate so as to cut off alternately equal areas on opposite sides of the curve we can determine the point for which the differences of phase will be least. Corresponding to each geometrical figure a second curve may be drawn with the same ordinates, and the phase at a given image point as abscissa. When only first order aberration is present the geometrical figure is an inclined straight line, the phase curve is a parabola, and the best focus will be at the mid-point of the projection of the straight line on the abscissa axis. This result is at variance with the geometrical prediction that the best position of focus is three times as far from the position where the paraxial rays come to a focus as from the intersection of a marginal ray with the axis.

Aplanatic Surfaces.—Although some lenses designed in the last few years show marked improvements on any that were produced before the World War, no system has yet been evolved which yields over a wide surface an image entirely free from aberration. Points imaged without differences of phase for monorythmic (often called monochromatic) light have long been named aplanatic points. A more restricted interpretation of the term, now universally adopted, was introduced by Abbe, the change involving the absence of aberrations when the object point makes small excursions in a definite surface. Connected aggregates of object and image points each having this property form a pair of aplanatic surfaces. Until recently our knowledge of the conditions under which such perfect imagery is possible were very limited—they amounted to hardly more than the plane mirror reflection, in which the whole object space is imaged without aberration, the aplanatic spheres discovered by Thomas Young for refraction at a sphere, and the trivial case of any single surface at which refraction occurs. A more general result is obtained by noting that if $\mathcal{E}$ is given explicitly as a function of the direction cosines (L, M, N) and (L', M', N'), the points

$$\left(\frac{\partial\mathcal{E}}{\mu\partial L},\frac{\partial\mathcal{E}}{\mu\partial M},\frac{\partial\mathcal{E}}{\mu\partial N}\right)\text{ and }\left(-\frac{\partial\mathcal{E}}{\mu'\partial L'},-\frac{\partial\mathcal{E}}{\mu'\partial M'},-\frac{\partial\mathcal{E}}{\mu'\partial N'}\right)$$

are on the incident and emergent rays respectively. Let us now suppose that $\mathcal{E}$ is a homogeneous function of the first order of three variables α, β, γ, each of which is a linear function of the six direction cosines, so that

$$\alpha=\alpha_0+\alpha_1\mu L+\alpha_2\mu M+\alpha_3\mu N-\alpha_4\mu' L'-\alpha_5\mu' M'-\alpha_6\mu' N'$$

where α_0, α_1, $\cdots$ are constants, with corresponding expressions for β and γ. Then

$$x=\alpha_1\mathcal{E}_\alpha+\beta_1\mathcal{E}_\beta+\gamma_1\mathcal{E}_\gamma,\qquad x'=\alpha_4\mathcal{E}_\alpha+\beta_4\mathcal{E}_\beta+\gamma_4\mathcal{E}_\gamma$$

with similar equations for y, y' and z, z'. It follows that $\mathcal{E}_\alpha$, $\mathcal{E}_\beta$, $\mathcal{E}_\gamma$ can be found in terms of x, y, z, and thus definite values of x', y', z' obtained. That is to say we obtain a one-one correspondence between these points of the object and image spaces. They will be object and image points if the length of the optical path between them is constant. Now this path is

$$\mathcal{E}+\mu'(L'x'+M'y'+N'z')-\mu(Lx+My+Nz)$$

or substituting from the equations for x, y, z, x', y', z' the path length is

$$\mathcal{E}-(\alpha-\alpha_0)\,\mathcal{E}_\alpha-(\beta-\beta_0)\,\mathcal{E}_\beta-(\gamma-\gamma_0)\,\mathcal{E}_\gamma;$$

that is, since $\mathcal{E}$ is homogeneous of the first order in α, β, γ, the path is

$$\alpha_0\mathcal{E}_\alpha+\beta_0\mathcal{E}_\beta+\gamma_0\mathcal{E}_\gamma$$

which depends only on the object point (x, y, z). There is thus no aberration in the image of this point. Moreover the aggregate of these object points forms a surface. For $\mathcal{E}$ satisfies a homogeneous relation of the form $\theta(\mathcal{E}, \alpha, \beta, \gamma)=0$, to which we can add three homogeneous equations

$$\frac{\theta_\alpha}{\mathcal{E}_\alpha}=\frac{\theta_\beta}{\mathcal{E}_\beta}=\frac{\theta_\gamma}{\mathcal{E}_\gamma}=-\epsilon_g.$$

On eliminating the ratios α, β and γ bear to $\mathcal{E}$ between these four equations we obtain a relation of the form $\phi(\mathcal{E}_\alpha, \mathcal{E}_\beta, \mathcal{E}_\gamma)=0$, and if $\mathcal{E}_\alpha$, $\mathcal{E}_\beta$, $\mathcal{E}_\gamma$ are replaced by their values in terms of x, y, z and of x', y', z' we obtain the equations of the object and image surfaces. From the linear character of α, β, γ it follows that the image surface can at most be a regular deformation of the object surface.

The converse process of constructing the eikonal which will yield given aplanatic surfaces can be carried out. It is merely a slight generalization of the process by which the eikonal was constructed for a given refracting surface.

In general a given optical system can have only one pair of aplanatic surfaces, for $\mathcal{E}$ can only be expressed in one way as a homogeneous function of the direction cosines. Spherically symmetrical systems are exceptional. For example if

$$\mathcal{E}=(\alpha^2+\beta^2+\gamma^2)^{\frac{1}{2}}$$

where $\alpha=pL+qL'$, $\beta=pM+qM'$, $\gamma=pN+qN'$,

we may, in consequence of the identities

$$L^2+M^2+N^2=1=L'^2+M'^2+N'^2,$$

rewrite the equation in the form $\mathcal{E}=(\alpha'^2+\beta'^2+\gamma'^2)^{\frac{1}{2}}$ where

$$\alpha'=qL+pL',\ \beta'=qM+pM',\ \gamma'=qN+pN'.$$

Corresponding to the first form we have the conjugate surfaces

$$\mu^2(x^2+y^2+z^2)=p^2,\ \mu'^2(x'^2+y'^2+z'^2)=q^2,$$

and corresponding to the second the pair

$$\mu^2(x^2+y^2+z^2)=q^2,\ \mu'^2(x'^2+y'^2+z'^2)=p^2.$$

Thus with a sphere, since its surface is self-conjugate, we may put $p=\mu r$, $q=\mu' r$, and the alternative solution shows that the concentric spheres of radii $r\mu'/\mu$ and $r\mu/\mu'$ are respectively aplanatic conjugate object and image surfaces.

Asymmetrical Systems.—We have discussed at some length the properties of symmetrical lens systems because they form by far the most important section of geometrical optics. The expressions that have been given enable all the ordinary problems to be dealt with—for example the paraxial expressions are sufficiently accurate to determine how large any simple lens must be to pass the rays the instrument should transmit. It is also a simple matter to derive a number of well-known conclusions from the general laws that have been given—for example that the use of an optical instrument will not enable a brighter image of an object subtending an appreciable angle to be formed on the retina of an observer's eye. The reader is not likely to encounter any difficulty arising from the use of prisms inserted for the reflection of light at plane surfaces into the system, for they are equivalent to the insertion of a thick plate of glass with plane parallel faces. Methods of designing prisms to produce desired results cannot be considered in detail here. As a rule a trigonometrical procedure is adopted, but algebraic methods employing matrices appear to offer decided advantages.

There remain systems of much importance without axial symmetry. The theory of such systems, though not difficult, is much more involved than that of axially symmetrical systems. Taking systems in which all the surfaces are met normally by some straight line, and yield symmetrical sections when cut by any plane through this line, which may be called the axis, we find that in place of the second degree matrix for the axially symmetrical system we have to adopt a square matrix of the fourth degree, with sixteen constituent elements. Between these sixteen quantities six independent identities subsist, so that at most there are ten degrees of freedom for paraxial rays. For an account of these quantities, their connections with the positions of the rays and with various expressions giving the lengths of paths through the system, reference should be made to the *Transactions of the Optical Society*. When we proceed to higher order terms representing aberrations the complexity of the theory is enhanced. For example corresponding to the six coefficients for the lowest order monorythmic aberrations in axially symmetric systems we have in these unsymmetrical systems no less than thirty-five coefficients.

Experimental Methods.—The marked changes in the way optical instruments have come to be regarded in recent years is reflected in experimental applications of the theory. A good example is afforded by the use of modified types of Michelson interferometers for the testing of optical instruments. This application of interference is due to F. Twyman. An instrument of this type, equipped for varied work, has been constructed by Messrs. Adam Hilger, Ltd., for the National Physical Laboratory, at Teddington, England. Many other interference methods have recently been described. Space will not permit us to discuss many interesting points which arise in the use of these and other methods of investigating the properties of optical instruments experimentally. (*See* LENS.)

BIBLIOGRAPHY.—Nearly all authorities deal with the geometrical theory only, and some are chiefly of value on account of miscellaneous articles.

See for historical interest mainly: H. Coddington, *Treatise on the Reflexion and Refraction of Light;* W. R. Hamilton, "Theory of Systems of Rays" (4 papers from the *Proceedings of the Royal Irish Academy* which serve as a starting point for modern work); R. Smith, *Compleat System of Opticks.*

More modern works are: S. Czapski and O. Eppenstein, *Grundzüge der Theorie der optischen Instrumente;* H. Geiger and K. Scheel, *Handbuch der Physik; XVIII. H. Konen, Geometrische Optik;* R. T. Glazebrook, *Dictionary of Applied Physics; IV. Optics;* R. S. Heath, *Geometrical Optics;* R. A. Herman, *Geometrical Optics;* M. von Rohr (trans. R. Kanthack), *Formation of Images in Optical Instruments;* J. P. C. Southall, *Principles and Methods of Geometrical Optics;* Steinheil and Voit (trans. J. W. French), *Applied Optics;* G. C. Steward: *The Symmetrical Optical System* (Tract); H. D. Taylor, *A System of Applied Optics.*

For the physical principles involved reference may be made to the optical papers of the late Lord Rayleigh. The writings of A. Gullstrand are important for the optics of spectacle lenses.

Most recent work has been described in journals devoted to optics, of which the chief are the *Transactions of the Optical Society, Revue d'Optique, Journal of the Optical Society of America,* and *Rivista d'Ottica.*

Valuable contributions will also be found in *Zeitschrift für Instrumentenkunde, Die Naturwissenschaften, Phil. Trans., Proceedings of the Physical Society,* and many others. An extensive bibliography is given by Czapski and Eppenstein. (T. SM.)

OPTIMISM, in philosophy, is the theory that the world is the best possible, or that life is worth living (to allude to the popular form of the problem).

For a discussion *see* PESSIMISM; PLATO; LEIBNITZ, GOTTFRIED WILHELM; HEGEL, GEORG WILHELM FRIEDRICH; also J. Sully, *Pessimism* (1877).

OPTION, the action of choosing, choice or the opportunity of choosing. In ecclesiastical law option was the right claimed by an archbishop to select one benefice from the diocese of a newly appointed bishop, the next presentation to which would fall to his, the archbishop's, patronage. This right was abolished in the early 19th century.

For the stock exchange options *see* OPTIONS (STOCK). Local option or local veto in politics is the power given to the electorate of a particular district to choose whether licences for the sale of intoxicating liquor shall be granted or not. (*See* LIQUOR LAWS AND LIQUOR CONTROL.)

OPTIONS (STOCK). Essentially, a stock option in security markets is a contract, paid for in advance, in which the holder has the right to buy (in the case of a "call" contract) or sell (in the case of a "put" contract) a specified number of shares of stock (generally 100) at a fixed price (normally the market price at the time the contract is made) at any time within the period covered

by the contract (usually 30, 60 or 90 days, or 6 months).

Consider the speculative possibility first. Let us assume the investor feels that XYZ stock is low priced at $70 a share and that it could advance to $85 a share in three months. To buy 100 shares under 75% margin rules would require a cash investment of $5,250. Unwilling to tie up this amount of cash and take the market risk that such a commitment involves, the investor buys a "call" option for $400, giving him the right to buy 100 shares at 70 within 90 days.

In that period, suppose XYZ climbs to 82. The investor could exercise his right to buy 100 shares at 70 from the endorser of the contract (a member firm of the New York Stock exchange) and immediately sell it in the open market at 82 for a profit of $1,200 less $400, the price of the contract, and usual brokerage commissions and taxes. If his judgment is wrong and XYZ drops to 50, his loss is limited to $400 as the price of the call option whereas an outright owner of the stock would have a paper loss of $2,000 and the possibility of further decline. At no time is the possible loss greater than the cost of the option contract.

To show the use of a put contract for speculation, let us consider the following. The investor feels that XYZ selling at 70 has a good chance of declining to possibly 50 in the next 90 days. He buys a "put" option contract at 70 good for 90 days for $350. If at any time in the 90-day period XYZ should decline to 50, he buys 100 shares in the market at 50 and delivers it to the maker of the put contract at 70, showing a profit of $2,000 less $350, the cost of the option contract less brokerage commissions and taxes.

The protective feature of options may be explained as follows. A person owns 100 shares of XYZ selling at 70; believing that some political or other event might change the course of the stock temporarily, he buys a put option at 70 for 90 days for $350. Now through his put contract, he is guaranteed that regardless of how low the stock should decline in the next 90 days, he can deliver his stock at 70 to the maker of the contract. On the other hand, if the expected decline does not take place and instead the market rises and the stock goes to 85, his profit from the advance in the value of the security has more than offset his cost of $350 for the protection.

The call option serves the same purpose in insuring against unlimited loss in connection with a short sale. For example: a man short 100 shares of stock at 70 with no protection of a call contract has an unlimited liability. But the man who, when he sells short at 70, protects his commitment with a call contract at 70 for 90 days at a cost of $400 knows that even if the stock should sell at 100 in 90 days he can cover his short position by calling for his stock at 70. Thus his loss is limited to $400 plus commissions instead of an actual market loss of $3,000.

A call contract can be useful to an owner of stock who, because of need for cash, desires to sell his security and still would like to have an interest in the stock. As an example, a man owns 100 shares of XYZ which he bought at 70 and is now selling at 85. He sells his stock in the market at 85 and buys a call option contract at 85 good for 90 days for $400. If after selling his stock XYZ continues to rise, he can in the 90 days recapture the stock at 85 through his call option.

If on the other hand, however, the stock should decline again to 70, he is in a position to buy back at 70 the stock which he sold at 85. While the cost of such "recapture protection" was $400, the gain afforded by the ability to buy back the stock 15 points lower than where it was sold made the purchase of the call worth while.

Makers of Options.—The put on XYZ mentioned above was probably sold by an individual or company who would be willing to issue a contract guaranteeing to the holder of the contract that for such $350 premium they would accept 100 shares of XYZ at 70 any time during the life of the contract.

If the stock should decline and the issuer of such a contract has the stock delivered to him at 70, his cost would be 70 less the $350 already received for the contract or a price of 66½. If the stock is not put to him, he has benefited by the $350 premium which he considered an adequate return in 90 days on the $7,000 investment.

The seller of a call on the other hand is probably one who owns XYZ and who for the sum of $400 would "give" someone a call on his stock at the current price of 70 good for 90 days. If the stock is called, the holder of the security loses his 100 shares at 70 plus the $400 already received. In other words, he has sold his stock at a price equivalent to 74. On the other hand, if the call is not exercised, the seller of the call has benefited by the $400 received in premium.

Practically, all of the put and call option business in the United States is handled by about 25 option dealers located in New York who operate through an association. Quotes on put and call option contracts may be obtained through local brokers or directly from a dealer in options. Orders to buy options may be placed in the same way. All of the contracts in which they deal are guaranteed or endorsed by member firms of the New York Stock exchange and this Association of Put and Call Brokers and Dealers, Inc., operates under the supervision of the Securities and Exchange commission. (Ht. F.)

OPTOMETRY is the science of vision care. The term, first adopted by the American Optometric association in 1904, also came into general use in Canada and Australia, and to some extent in England and other countries in designating those who are usually called refracting opticians in those countries.

Optometry performs three out of four ocular examinations in the United States, the remaining being performed by ophthalmologists and oculists who are physicians specializing in eye care.

Optometry emphasizes functional vision. It holds that both the visual examination and the corrective measures applied should take into account the patient's specific requirements. An office worker, for example, requires special attention to near-point vision because most of his critical seeing is within arm's length. A crane operator in industry, by contrast, requires special attention to distant vision because his critical seeing is at a distance of 20 ft. or more.

This functional emphasis led to the development of many examination techniques and corrective measures, going beyond the mechanistic theory that seeing is done solely by a cameralike eye. The common letter chart read at a distance of 20 ft. is only a small part of the comprehensive optometric analysis of a patient's vision. Visual skills tests are made which enable the optometrist to analyze visual performance for long periods of sustained concentration at near distances.

Organized optometry conducts extensive activities for the prevention of visual problems. These are directed toward school vision, occupational vision and highway vision. Stress is laid on the proper seeing environment in schools, factories and offices and more comprehensive examinations are urged for the purpose of discovering visual handicaps before they become serious. Psychological and neurological concepts led optometry to the application of visual training as a corrective measure for many anomalies that could not be corrected by lenses alone.

Scientific visual training, as applied by optometry and also by some medical practitioners, should not be confused with self-taught "eye exercises."

The minimum educational requirement for optometry in the United States is five years of college training. An applicant for state licensing board examination must be a graduate of a school or college of optometry accredited by the individual state board.

The American Optometric association, national organization of the profession in the United States, was formed originally in 1897 by opticians specializing in refraction. The first state to license optometry was Minnesota, which enacted an optometry statute in 1901. The American Academy of Optometry, dedicated to scientific and educational interests, was founded in 1922.

Among the founders of optometry as a specialized profession were Andrew Jay Cross (1855–1925) and Charles F. Prentice (1854–1946). Cross led in the development of education for optometry, and it was largely through his effort that Columbia university inaugurated its first two-year course in 1910 with Cross as an instructor.

Prentice was a leader in the enactment of state legislation to

maintain high standards by licensing optometrists.

(E. M. S.)

OPTOPHONE, an instrument invented by E. E. Fournier d'Albe in 1914 which enables the blind to read ordinary letterpress such as printed books or newspapers. The invention thus places within reach of the blind the entire range of world literature, while previously their only means of reading—by raised letter systems—necessitated special books, both bulky and expensive.

The instrument depends for its action upon the chemical element, selenium, the electrical conductivity of which varies greatly in accordance with the amount of light to which it is exposed. Such a light-sensitive selenium bridge is placed between two separate conducting lines of graphite resting on a porcelain tablet and the whole connected in series with an electric battery to a telephone receiver.

A beam of light is rendered intermittent by the interposition of a revolving siren disk and is then concentrated into a small bright point on the letter to be read. This is reflected back onto the selenium bridge. As the selenium bridge is exposed to the forms of letters in the line traversed, its changes in conductivity produce a succession of varying notes and chords in the telephone receiver, each letter having its characteristic sound. That is its simple form.

Actually in the regular instrument a row of five or six luminous points just filling up the size of the tallest letters to be read is substituted for a single point, and each point is given a different frequency by suitably perforating the disk. A blind reader does not analyze the resulting sounds, but soon comes to recognize the general sound of each letter and in time knows his alphabet of sounds.

Later in his practice the succession of sounds which make up certain words becomes familiar. Controlling apparatus to regulate the speed and position of the tracer is designed with a view to ease of manipulation by blind persons. After 1920 developments in amplification enabled the sounds to be made audible to any number in a room if desired, though individual receivers were retained for silent reading.

(*See* SELENIUM CELLS.)

OPUS ('Ὀποῦς), in ancient Greece, the chief city of the Opuntian Locrians; the walls of the city were built on a hill about 6 mi. S.E. of the modern Atalante and about 1 mi. from the channel which separates the mainland from Euboea.

It was mentioned in the Homeric catalogue among the towns of the Locrians, who were led by Ajax Oileus; there were games called Aiantea and an altar at Opus in honour of Ajax. Opus was also the birthplace of Patroclus.

Pindar's Ninth Olympian ode is mainly devoted to the glory and traditions of Opus.

Its founder was Opus the son of Zeus and Protogeneia, the daughter of an Elian Opus, or, according to another version, of Deucalion and Pyrrha, and the wife of Locros.

The Locrians deserted the Greek side in the Persian wars; they were among the allies of Sparta in the Peloponnesian War. In the struggle between Philip V of Macedon and the Romans, the town went over to the latter in 197 B.C.; however, the Acropolis continued to hold out for Philip until his defeat at Cynoscephalae (Livy xxxii, 32).

The town suffered from earthquakes, such as that which destroyed the neighbouring Atalante in 1894.

OPZOOMER, CORNELIUS WILLIAM (1821–1892), Dutch philosopher, was born in Rotterdam on Sept. 20, 1821. He studied at the University of Leyden, receiving the degree of doctor of law in 1845.

In 1846 Opzoomer was appointed professor of philosophy at the University of Utrecht, which position he held the remainder of his life. His specialty was jurisprudence and many of his numerous writings were in that field, notably *Scheiding van Kerk en Staat* (1875), in which he sustained the primacy of the civil power, and a commentary on the civil code of the Netherlands (11 vol., 1864–87).

His greatest influence, however, was in the field of philosophy. He was an empiricist of the positivistic type. His thought can best be traced in such of his writings as *Der Weg de Wetenschap* (1851), *Wetenschap en Wijsbegeerte* (1857), *Het Wezen der Kennis* (1863), *De Waarheid en hare Kenbronnen* (1863), *De Godsdienst* (1864), *Goethe's Godsdienst* (1868) and *Ein Nieuwe Kritick der Wijsbegeerte* (1871). He advocated expulsion of the unscientific from religion, believing that the latter would be left unimpaired, and that it would lead to the reconciliation of religion and science and bring about a new Reformation. Though vigorously opposed at first his views rapidly gained adherents and he became the leader of the liberals and the founder of modern theology in his country.

Opzoomer was also a widely read man of letters, translated the *Antigone* of Sophocles and the *Julius Caesar* of William Shakespeare into Dutch, and published (1872) a volume of critical studies on the great English dramatist. He died in Osterbeck on Aug. 23, 1892.

ORACH or MOUNTAIN SPINACH (also called sea purslane), known botanically as *Atriplex hortensis* (family, Chenopodiaceae), is a tall-growing hardy annual, whose leaves, though coarsely flavoured, are very often used as a substitute for spinach when young.

The white and the green are the most desirable varieties. The plant should be grown quickly in rich soil. It may be sown in rows two feet apart, and about the same distance in the row, about April, and for succession again in June. If needful, water must be given freely, so as to maintain a rapid growth. A variety, with reddish foliage, is a hardy annual three to four feet high and sometimes grown for ornament.

ORACLE, a special place where a deity is supposed to give a response, by the mouth of an inspired priest, to the inquiries of his votaries, or the actual response. (Lat. *oraculum,* from *orare,* to speak; the corresponding Greek word is μαντεῖον or χρηστήριον.) (*See* DIVINATION; MAGIC.) The whole question of oracles is bound up with that of magic. They are commonly found in the earlier stages of religious culture among different nations. But it is as an ancient Greek institution that they are most interesting historically.

A characteristic feature of Greek religion which distinguishes it from many other systems of advanced cult was the wide prevalence of a ritual of divination and the prominence of certain oracular centres which were supposed to give voice to the will of Providence.

An account of the oracles of Greece is concerned with the historical question about their growth, influence and career. But it is convenient to consider first the anthropologic question concerning the methods of divination practised in ancient Greece, their significance and the original ideas that inspired them.

In the Greek world the methods of divination were of great variety, but nearly all can be traced among other communities, primitive and advanced, ancient and modern. The most obvious and useful classification of them is that of which Plato was the author, distinguishing between: (1) the "sane" form of divination; and (2) the ecstatic, enthusiastic or "insane" form (Phaedrus p. 244). The first method appears to be cool and scientific, the diviner (μάντις) interpreting certain signs according to fixed principles of interpretation. The second is worked by the prophet, shaman or Pythoness, who is possessed and overpowered by the deity, and in temporary frenzy utters mystic speech under divine suggestion. To these we may add another form (3) divination by communion with the spiritual world in dreams or through intercourse with the departed spirit: this resembles class (1) in that it does not necessarily involve ecstasy, and class (2) in that it assumes immediate rapport with some spiritual power.

This article will first give typical examples of these processes of discovering the divine will; then the history of Delphi, the leading centre of divination, will be sketched.

Methods that fall under class (1) may be subdivided according as they deal with the phenomena of the animate or the inanimate world; although this distinction would not be relevant in the period of primitive animistic thought. The Homeric poems attest that auguries from the flight and actions of birds were

commonly observed in the earliest Hellenic period as they occasionally were in the later, but we have little evidence that this method was ever organized as it was at Rome into a regular system of state-divination, still less of state-craft. We can only quote the passage in the *Antigone* where Sophocles describes the method of Teiresias, who keeps an aviary where he studies and interprets the flight and the cries of the birds; it is probable that the poet was aware of some such practice actually in vogue. But normally the Greek augur drew omens from the cries or actions of some bird or beast casually met with (as Hom. *Il.* xiii. 521; Aesch. *Agam.* 109; Serv. Virg. *Aen.* iv. 377; Paus. ii. 19. 3); it is very rare to find such omens habitually consulted in any public system of divination sanctioned by the State. We hear of a shrine of Apollo at Sura in Lycia (Steph. Byz. *s.v.* Σοῦρα; Plutarch, *De sollert. anim.* p. 976 c; Ael. *Nat. anim.* xii. 1) where omens were taken from the movements of the sacred fish that were kept there in a tank; and again of a grove consecrated to this god in Epirus, where tame serpents were kept, and fed by a priestess, who could predict a good or bad harvest according as they ate heartily or came willingly to her or not (Ael. *Nat. anim.* xi. 2).

But the method of animal divination that was most in vogue was the inspection of the inward parts of the victim offered upon the altar, and the interpretation of certain marks found there according to a conventional code. A conspicuous example of an oracle organized on this principle was that of Zeus at Olympia, where soothsayers of the family of the Iamidae prophesied partly by the inspection of entrails, partly by the observation of certain signs in the skin when it was cut or burned (Schol. Pind. *Ol.* 6. 111). Another less familiar procedure that belongs to this subdivision is that which was known as divination διά κληωδόνν, which might sometimes have been the cries of birds, but in an oracle of Hermes at the Achaean city of Pharae were the casual utterances of men. Pausanias (VII. 22. 2) tells us how this was worked. The consultant came in the evening to the statue of Hermes in the market-place that stood by the side of a hearth-altar to which bronze lamps were attached; having kindled the lamps and put a piece of money on the altar, he whispered into the ear of the statue what he wished to know; he then departed, closing his ears with his hands, and whatever human speech he first heard after withdrawing his hands he took for a sign. The same custom seems to have prevailed at Thebes in a shrine of Apollo, and in the Olympian oracle of Zeus (Farnell, *Cults* iv. 221).

Of omens taken from what we call the inanimate world salient examples are those derived from trees and water. Both were in vogue at Dodona, where the ecstatic method of prophecy was never used; we hear of divination there from the bubbling stream, and still more often of the "talking oak"; under its branches may once have slept the Selloi, who interpreted the sounds of the boughs. (Hom. *Il.* xvi. 233, *Od.* xiv. 327; Hesiod, *ap.* Schol. Soph. *Trach.* 1169; Aesch. *Prom. Vinct,* 820). At Corope in Thessaly we hear vaguely of an Apolline divination by means of a branch of the tamarisk tree (Nicander, *Theriaka,* 612, Schol.), and there is a late record that at Daphne near Antioch oracles were obtained by dipping a laurel leaf or branch in a sacred stream (Robertson-Smith *Relig. Sem.* p. 128). We find water divination at Daphne, Taenarum and Patrae. Thunder magic, which was practised in Arcadia, is usually associated with thunder divination; but of this, which was so much in vogue in Etruria (*see* HARUSPICES) and at Rome, the evidence in Greece is singularly slight. Once a year watchers took their stand on the wall at Athens and waited till they saw the lightning flash from Harma, which was accepted as an auspicious omen for the setting out of the sacred procession to Apollo Pythius at Delphi; and the altar of Zeus Σημαλέος, the sender of omens, on Mount Parnes, may have been a religious observatory of meteorological phenomena (Paus. i. 32. 2). No doubt such a rare and portentous event as the fall of a meteor-stone would be regarded as ominous, and the State would be inclined to consult Delphi or Dodona as to its divine import.

We may conclude the examples of this main department of μαντική by mentioning a method that seems to have been much in vogue in the earlier times, that which was called ἡ διά ψήφων μαντική, or divination by the drawing or throwing of lots; these must have been objects, such as small pieces of wood or dice, with certain marks inscribed upon them, drawn casually or thrown down and interpreted according to a certain code. This was practised at Delphi and Dodona by the side of the more solemn procedure; we hear of it also in the oracle of Heracles at Bura in Achaea (Cic. *De div.* i. 76; Suid. *s. v.* πυδώ; Paus. vii. 25. 10). It is this method of "scraping" or "notching" (χράειν) signs on wood that explains probably the origin of the words χρησμός, χρῆσθαι, ἀναιρεῖν for oracular consultation and deliverance. In Italy, oracles by lot (*sortes*) are the only native kind of whose existence we are certain; that of *Fortuna* at Praeneste was the best known.

All these methods are world-wide, and may depend on belief in the *mana* of the bird, spring, lot, etc., or in the controlling influence of a spirit or god. And, again, if we are to understand the most primitive thought, we probably ought to conceive of it as regarding the omen not as a mere sign, but in some confused sense as a cause of that which is to happen. By sympathetic magic the flight of the bird, or the appearance of the entrails, is mysteriously connected, as cause with effect, with the event which is desired or dreaded. When of the three beasts over which three kings swore an oath of alliance, one died prematurely and was supposed thereby to portend the death of one of the kings (Plut. *Vit. Pyrrh.* c. 6), or when in the Lacedaemonian sacrifice the head of the victim mysteriously vanished, and this portended the death of their naval commander (Diod. Sic. xiii. 97), these omens would be merely signs of the future for the comparatively advanced Hellene; but we may discern at the back of this belief one more primitive still, that these things were somehow casually or sympathetically connected with the kindred events that followed.

The other branch of the mantic art, the ecstatic or inspired, has had the greater career among the peoples of the higher religions; it is no doubt of great antiquity, and it is found still existing at a rather low grade of savagery. Therefore it is unsafe to infer from Homer's silence about it that it only became prevalent in Greece in the post-Homeric period. It did not altogether supersede the simpler method of divination by omens; but being far more impressive and awe-inspiring, it was adopted by some of the chief Apolline oracles, though never by Dodona.

The most salient example of it is afforded by Delphi. In the historic period, and perhaps from the earliest times, a woman known as the Pythia was the organ of inspiration, and it was generally believed that she delivered her oracles under the direct afflatus of the god. The divine possession worked like an epileptic seizure, and was exhausting and might be dangerous; nor is there any reason to suppose that it was simulated. This communion with the divinity needed careful preparation. Originally, as it seems, virginity was a condition of the tenure of the office; for the virgin has been often supposed to be the purer vehicle for divine communication; but later the rule was established that a married woman over 50 years of age should be chosen, with the proviso that she should be attired as a maiden. As a preliminary to the divine possession, she appears to have chewed leaves of the sacred laurel, and then to have drunk water from the prophetic stream called Kassotis which flowed underground. But the culminating point of the afflatus was reached when she seated herself upon the tripod; and here, according to the belief of at least the later ages of paganism, she was supposed to be inspired by a mystic vapour that arose from a fissure in the ground. Against the ordinary explanation of this as a real mephitic gas producing convulsions, there seem to be geological and chemical objections (*see* Oppe, "The chasm at Delphi," *Journ. Hell. Stud.*, 1904); nor have the recent French excavations revealed any chasm or gap in the floor of the temple. But the strong testimony of the later writers, especially Plutarch (*De defectu Orac.* c. 43), cannot wholly be set aside; and we can sufficiently reconcile it with the facts if we suppose a small crack in the floor through which a draught of air was felt to ascend. This, combining with the other mantic stimulants used, would be enough to throw a believing medium into the condition, familiar enough nowadays, of a "trance." It is probable that what she uttered were only unintelligible murmurs,

and that these were interpreted into relevance and set in metric or prose sentences by the "prophet" and the "holy ones" or Ὅσιοι as they were called, members of leading Delphic families, who sat round the tripod, who received the questions of the consultant beforehand, probably in writing, and usually had considered the answers that should be given.

Examples of the same enthusiastic method can be found in other oracles of Apollo. At Argos, the prophetess of the Apollo Pythius attained to the divine afflatus by drinking the blood of the lamb that was sacrificed in the night to him (Paus. ii. 24. 1); this is obviously a mantic communion, for the sacrificial victim is full of the spirit of the divinity. And we find the same process at the prophetic shrine of Ge at Aegae in Achaea, where the prophetess drank a draught of bull's blood for the same purpose (Farnell, *op. cit.* iii. 11). In the famous oracle shrines of Apollo across the sea, at Clarus and Branchidae near Miletus (the prophetic fountain at Branchidae is attested by Strabo, p. 814, and in a confused mystic passage of Iamblichus, *De Myst.*, 3, 11), the divination was of the same ecstatic type, but produced by a simple draught of holy water. The Clarian prophet fasted several days and nights in retirement and stimulated his ecstasy by drinking from a subterranean spring which is said by Pliny to have shortened the lives of those who used it (*Nat. Hist.* ii. 232). Then, "on certain fixed nights after many sacrifices had been offered, he delivered his oracles, shrouded from the eyes of the consultants" (Iamb. *loc. cit.*).

The divination by "incubation" was allied to this type, because though lacking the ecstatic character, the consultant received direct communion with the god or departed spirit. He attained it by laying himself down to sleep or to await a vision, usually by night, in some holy place, having prepared himself by a course of ritualistic purification. Such consultation was naturally confined to the underworld divinities or to the departed heroes. It appears to have prevailed at Delphi when Ge gave oracles there before the coming of Apollo, and among the heroes Amphiaraus, Calchas and Trophonius are recorded to have communicated with their worshippers in this fashion. And it was by incubation that the sick and diseased who repaired to the temple of Epidaurus received prescriptions from Asclepius.

Turning now to the history of oracles in Greece, we know that the leading one, Delphi, was a seat of prophecy from the earliest days of Greek tradition. Ge, Themis and perhaps Poseidon had given oracles here before Apollo. But it is clear that he had won it in the days before Homer, who attests the prestige and wealth of his Pythian shrine; and it seems clear that before the Dorian conquest of the Peloponnese a Dryopian migration had already carried the cult of Apollo Pythius to Asine in Argolis. Also the constitution of the Amphictyones, "the dwellers around the temple," reflects the early age when the tribe rather than the city was the political unit, and the Dorians were a small tribe of north Greece. The original function of these Amphictyones was to preserve the sanctity and property of the temple; but this common interest early developed a certain rule of intertribal morality. By the formula of the Amphictyonic oath preserved by Aeschines, which may be of great antiquity, the members bound themselves "not to destroy any city of the league, not to cut any one of them off from spring-water, either in war or peace, and to war against any who violated these rules." We discern here that Greek religion offered the ideal of a federal national union that Greek politics refused to realize.

The next stage in the history of the oracle is presented by the legend of the Dorian migration. For we have no right to reject the strong tradition of the Delphic encouragement of this movement, which well accounts for the devotion shown by Sparta to the Pythian god from the earliest days; and accounts also for the higher position that Delphi occupied at the time when Greek history is supposed to begin.

We have next to consider a valuable record that belongs to the end of the 8th century or beginning of the 7th, the Homeric hymn to Apollo, which describes the coming of the Dolphin-god Δελφίνιος to Pytho, and the organization of the oracle by Cretan ministers. Of this Cretan settlement at Delphi there is no other literary evidence, and the Ὅσιοι who administered the oracle in the historic period claimed to be of aboriginal descent. Yet recent excavation has proved a connection between Crete and Delphi in the Minoan period; and there is reason to believe that in the 8th century some ritual of purification, momentous for the religious career of the oracle, was brought from Crete to Delphi, and that the adoption of this latter name for the place which had formerly been called Πυθώ synchronized with the coming of Apollo Delphinius.

The influence of Delphi was great in various ways. We may first consider its political influence upon the other states. The practice of a community consulting an oracle on important occasions undoubtedly puts a powerful weapon into the hands of the priesthood, and might lead to something like a theocracy. And there are one or two ominous hints in the *Odyssey* that the ruler of the oracle might overthrow the ruler of the land. Yet owing to the healthy temperament of the early Greek, the civic character of the priesthood, the strength of the autonomous feeling, Greece might flock to Delphi without exposing itself to the perils of sacerdotal control. The Delphic priesthood, content with their rich revenues, were probably never tempted to enter upon schemes of far-reaching political ambition, nor were they in any way fitted to be the leaders of a national policy. Once only, when the Spartan State applied to Delphi to sanction their attack on Arcadia, did the oracle speak as if, like the older papacy, it claimed to dispose of territory (Herod. i. 66)—"Thou askest of me Arcadia; I will not give it thee." But here the oracle is on the side of righteousness, and it is the Spartan that is the aggressor. In the various oracles that have come down to us, many of which must have been genuine and preserved in the archives of the State that received them, we cannot discover any marked political policy consistently pursued by the "holy ones" of Delphi. As conservative aristocrats they would probably dislike tyranny; their action against the Peisistratidae was interested, but one oracle contains a spirited rebuke to Cleisthenes, while one or two others, perhaps not genuine, express the spirit of temperate constitutionalism. As exponents of an Amphictyonic system they would be sufficiently sensitive of the moral conscience of Greece to utter nothing in flagrant violation of the "ius gentium." In one department of politics, the legislative sphere, it has been supposed that the influence of Delphi was direct and inspiring. Plato and later writers imagined that the Pythia had dictated the Lycurgan system, and even modern scholars like Bergk have regarded the ῥῆτραι of Sparta as of Delphic origin. But a severer criticism dispels these suppositions. The Delphic priesthood had neither the capacity nor probably the desire to undertake so delicate a task as the drafting of a code. They might make now and again a general suggestion when consulted, and, availing themselves of their unique opportunities of collecting foreign intelligence, they might often recommend a skilful legislator or arbitrator to a state that consulted them at a time of intestine trouble. Finally, a legislator with a code would be well advised, especially at Sparta, in endeavouring to obtain the sanction and the blessing of the Delphic god, that he might appear before his own people as one possessed of a religious mandate. In this sense we can understand the stories about Lycurgus.

There is only one department of the secular history of Greece where Delphi played a predominant and most effective part, the colonial department. The great colonial expansion of Greece, which has left so deep an imprint on the culture of Europe, was in part inspired and directed by the oracle. For the proof of this we have not only the evidence of the χρησμοί preserved by Herodotus and others, such as those concerning the foundation of Cyrene, but also the worship of Apollo Ἀρχηγέτης, "the Founder," prevalent in Sicily and Magna Graecia, and the early custom of the sending of tithes or thanksgiving offerings by the flourishing western states to the oracle that had encouraged their settlements.

Apollo was already a god of ways, Ἀγυιεύς, who led the migration of tribes before he came to Delphi. And those legends are of some value that explain the prehistoric origin of cities such as Magnesia on the Maeander, the Dryopian Asine in the Pelopon-

nese, as due to the colonization of temple-slaves, acquired by the Pythian god as the tithe of conquests, and planted out by him in distant settlements. The success of the oracle in this activity led at last to the establishment of the rule that Herodotus declares to be almost universal in Greece, namely, that no leader of a colony would start without consulting Delphi. Doubtless in many cases the priesthood only gave encouragement to a preconceived project. But they were in a unique position for giving direct advice also, and they appear to have used their opportunities with great intelligence.

Their influence on the state cults can be briefly indicated, for it was not by any means far-reaching. They could have felt conscious of no mission to preach Apollo, for his cult was an ancient heritage of the Hellenic stocks. Only the narrower duty devolved upon them of impressing upon the consultants the religious obligation of sending tithes or other offerings. Nevertheless their opportunity of directing the religious ritual and organization of the public worships was great; for Plato's view (Rep. 427A) that all questions of detail in religion should be left to the decision of the god "who sits on the *omphalos*" was on the whole in accord with the usual practice of Greece. Such consultations would occur when the State was in some trouble, which would be likely to be imputed to some neglect of religion, and the question to the oracle would commonly be put in this way—"to what god or goddess or hero shall we sacrifice?" The oracle would then be inclined to suggest the name of some divine personage hitherto neglected, or of one whose rites had fallen in decay. Again, Apollo would know the wishes of the other divinities, who were not in the habit of directly communicating with their worshippers; therefore questions about the sacred land of the goddesses at Eleusis would be naturally referred to him. From both these points of view we can understand why Delphi appears to have encouraged the tendency towards hero-worship which was becoming rife in Greece from the 7th century onwards. But the only high cult for which we can discover a definite enthusiasm in the Delphic priesthood was that of Dionysus. And his position at Delphi, where he became the brother-deity of Apollo, sufficiently explains this.

As regards the development of religious morality in Greece, we must reckon seriously with the part played by the oracle. The larger number of deliverances that have come down to us bearing on this point are probably spurious, in the sense that the Pythia did not actually utter them, but they have a certain value as showing the ideas entertained by the cultivated Hellene concerning the oracular god. On the whole, we discern that the moral influence of Delphi was beneficent and on the side of righteousness. It did nothing, indeed, to abolish, it may even have encouraged at times, the barbarous practice of human sacrifice, which was becoming abhorrent to the Greek of the 6th and 5th centuries; but a conservative priesthood is always liable to lag behind the moral progress of an age in respect of certain rites, and in other respects it appears that the "Holy Ones" of Delphi kept well abreast of the Hellenic advance in ethical thought. An oracle attributed to the Pythoness by Theopompus (Porph. *De abstinentia,* 2, 16 and 17) expresses the idea contained in the story of "the widow's mite," that the deity prefers the humble offering of the righteous poor to the costly and pompous sacrifice of the rich. Another, of which the authenticity is vouched for by Herodotus (vi. 86), denounces the contemplated perjury and fraud of a certain Glaucus, and declares to the terrified sinner that to tempt God was no less a sin than to commit the actual crime. A later χρησμός, for which Plutarch (*De Pyth. Or.,* p. 404 B) is the authority, embodies the charitable conception of forgiveness for venial faults committed under excessive stress of temptation: "God pardons what man's nature is too weak to resist." And in one most important branch of morality, with which progressive ancient law was intimately concerned, namely, the concept of the sin of homicide, we have reason for believing that the Apolline oracle played a leading part. Perhaps so early as the 8th century, it came to lay stress on the impurity of bloodshed and to organize and impose a ritual of purification; and thus to assist the development and the clearer definition of the concept of murder as a sin and the growth of a theory of equity which recognizes extenuating or justifying circumstances (Farnell, *Cults.* iv. 300). Gradually, as Greek ethics escaped the bondage of ritual and evolved the idea of spiritual purity of conscience, this found eloquent expression in the utterances imputed to the Pythia (Ael. *Var. Hist.* iii. 44; Anth. Pal. xiv. 71 and 74). Many of these are no doubt literary fictions; but even these are of value as showing the popular view about the oracular god, whose temple and tripod were regarded as the shrine and organ of the best wisdom and morality of Greece. The downfall of Greek liberty before Macedon destroyed the political influence of the Delphic oracle; but for some centuries after it still retained a certain value for the individual as a counsellor and director of private conscience. But in the latter days of paganism it was eclipsed by the oracles of Claros and Branchidae.

ORADEA MARE, a town of Transylvania; ceded to Hungary by Rumania in 1940. Pop. (1939) 82,687, mainly Magyar. It is situated in a plain on both banks of the river Crisul Repede, and is the seat of a Roman Catholic and of a Greek Uniate Bishopric (founded 1776). Among its principal buildings are the St. Ladislaus parish church, built in 1723, which contains the remains of the king St. Ladislaus (d. 1095), the Roman Catholic cathedral, built in 1752–1779, the Greek cathedral, the large rococo palace of the Roman Catholic bishop, built in 1778, and the archaeological and historical museum. There is a law academy, a seminary for priests, a modern school, a Roman Catholic and a Calvinistic gymnasium, a commercial academy, a training school for teachers and a secondary school for girls. Oradea Mare is an important railway junction; it possesses extensive manufactures of pottery and large distilleries, and carries on a brisk trade in agricultural produce, cattle, horses, fruit and wine.

Oradea Mare is a very old town; its bishopric was founded by St. Ladislaus in 1080. The town was destroyed by the Tatars in 1241. Peace was concluded here on Feb. 24, 1538 between Ferdinand I. of Austria and his rival John Zápolya, voivode of Transylvania. In 1556 it passed to Transylvania, but afterwards reverted to Austria. In 1598 the Turks besieged the fortress unsuccessfully, but took it in 1660 and held it till 1692. After World War I it was ceded to Rumania and in Aug. 1940 back to Hungary.

ORAKZAI, a Pathan tribe on the Kohat border of the North-West Frontier province of India. The Orakzais inhabit the mountains to the northwest of Kohat district, bounded on the N. and E. by the Afridis, on the S. by the Miranzai valley and on the W. by the Zaimukht country and the Safed Koh mountains. Their name means "lost tribes," and their origin is buried in obscurity; although they resemble the Afghans in language, features and many of their customs, they are rejected by them as brethren. One branch, the Ali Khel, has been traced to Swat, whence they were expelled by the other inhabitants, and it is not improbable that the whole tribe consists of refugee clans of the surrounding races. They are very wiry-looking mountaineers. (*See* Tirah).

ORAN, a city and port of Algeria, capital of the department and military division of the same name, stands at the head of the Gulf of Oran, on the Mediterranean, in 35° 44′ N., 0° 41′ W. The city is 261 mi. by rail W.S.W. of Algiers, 220 mi. E. of Gibraltar and 130 mi. S. of Cartagena, Spain. It is built on the steep slopes of the Jebel Murjajo, which rises to a height of 1,900 ft. The city was originally cut in two by the ravine of Wad Rehhi, now for the most part covered by boulevards and buildings. West of the ravine lies the old port, and above this rises what was the Spanish town, with the ancient citadel looking down on it. Few traces of Spanish occupation remain. The modern quarter rises, like an amphitheatre, to the east of the ravine. A ring of populous

suburbs, Montplaisant, Gambetta, Saint-Eugène, Eckmühl, encircle it from northeast to southwest. The Place d'Armes, built on the plateau above the ravine, contains a fine column commemorative of the battle of Sidi Brahim (1845), between the French and Abd-el-Kader. The Château Neuf, built in 1563 by the Spaniards and formerly the seat of the beys of Oran, is surrounded by the beautiful Promenade de l'Etang, which overlooks the port. The *kasbah* (citadel) or Château Vieux, used for military purposes, lies southwest of the Château Neuf. Behind the *kasbah* are Fort St. Grégoire and Fort Santa Cruz, crowning, at a height of 1,312 ft., the summit of the Aidur. The Grand Mosque (in rue Philippe) was erected with money paid as ransom for Christian slaves at the end of the 18th century, to commemorate the expulsion of the Spaniards.

Oran is the seat of a large trade. There is regular communication with Marseille, Cette, Barcelona, Valencia, Cartagena, Malaga, Gibraltar and the various ports on the Barbary coast. The harbour is sheltered by a large jetty stretching from west to east, parallel to the shore and more than 3,936 ft. long. The different basins which it protects include the old harbour (1868), the Aucour basin (1876), the Morocco basin (1914) and the Poincaré basin (1928). The surface of the water is about 100 ac., the length of the quays 6,879 ft., the extent of the platforms 1,722,240 sq.ft.; there is a dock railway station on the south quay. Oran is the terminus of the standard (4′8½″) gauge railway lines from Algiers and from Ujda via Tlemçen and Sidi-bel-Abbes, and of the 1.055-metre gauge line from Colomb-Bechar-Kenadsa, which penetrates 470 mi. toward the south. The construction of the standard gauge railway from Ujda to Fez, of the lines into eastern Morocco, and of the Trans-Saharan railway may be expected to increase the importance of the port. The tonnage of goods in 1938 totalled 3,046,884 (imports 1,440,447, exports 1,606,437).

The total population of Oran (1936) was 194,746 (46,157 natives and 148,589 Europeans.)

See Augustin Bernard, "Oran, port du Maroc et du Sahara," *Bull. Soc Géogr.* (Oran, 1928).

History.—Andalusian Arabs settled at Oran in the beginning of the 10th century. Important as a seaport, Oran was taken and retaken, pillaged and rebuilt, by the various conquerors of northern Africa. In the latter half of the 15th century under the sultans of Tlemçen it reached the height of its prosperity. Active commerce was maintained with the Venetians, the Pisans, the Genoese, the Marseilleais and the Catalans, who imported the produce of their looms, glasswares, tinwares and iron, and received in return ivory, ostrich feathers, gold-dust, tanned hides, grain and Negro slaves. Admirable woollen cloth and splendid arms were manufactured. The magnificence of its mosques and other public buildings, the number of its schools, and the extent of its warehouses shed lustre on the city; but luxury began to undermine its prosperity and its ruin was hastened by the conduct of the Moslem refugees from Spain, under whose influence the legitimate trade of the town gave place to piracy, Mers-el-Kebir becoming the stronghold of the pirates.

The Spaniards, animated by Cardinal Ximenes, determined to put a stop to the piracy. Mers-el-Kebir fell into their hands on Oct. 23, 1505, and Oran in May 1509. The latter victory, obtained with but trifling loss, was stained by the massacre of a third of the Mohammedan population. Cardinal Ximenes introduced the Inquisition, and also restored and extended the fortifications. The bey of Mascara seized Oran in 1708. The Spaniards recovered it in 1732, but found the maintenance of the place a burden rather than a benefit, the neighbouring tribes having ceased to deal with the Christians. The earthquakes of Oct. 8–Nov. 22, 1790, destroyed much of the town and a third of the garrison. Famine and sickness aggravated the situation when the bey of Mascara appeared before the town with 30,000 men. The Spanish commander held out till Aug. 1791. Bey Mohammed took possession of Oran in March 1792 and made it his residence instead of Mascara. The French army entered the city on Jan. 4, 1831, and took formal possession on Aug. 17.

In June 1940, at the time of the Franco-German armistice, a substantial portion of the French fleet took refuge at Oran and its naval base of Mers-el-Kebir. After fruitless negotiation by the British, with the purpose of preventing the vessels falling into axis hands, a British naval force made an attempt to destroy the ships (July 3, 1940). Several French vessels were sunk and others were severely damaged. Oran, one of the principal objectives in the Allied landings in North Africa, Nov. 8, 1942, was occupied Nov. 10, 1942, after the city had been encircled, against considerable resistance.

See M. D. Stott, *The Real Algeria* (1914). (P. W. I.)

ORANGE, HOUSE OF. The small principality of Orange, a district now included in the French department of Vaucluse, traces back its history as an independent sovereignty to the time of Charlemagne. William, surnamed *le Cornet,* who lived toward the end of the 8th century, is said to have been the first prince of Orange, but the succession is only certainly known after the time of Gerald Adhemar (*fl.* 1086). In 1174 the principality passed by marriage to Bertrand de Baux, and there were nine princes of this line. By the marriage of John of Châlons with Marie de Baux, the house of Châlons succeeded to the sovereignty in 1393. The princes of Orange-Châlons were (1) John I, 1393–1418, (2) Louis I, 1418–1463, (3) William VIII, 1463–1475, (4) John II, 1475–1502, (5) Philibert, 1502–1530. Philibert was a great warrior and statesman, who was held in great esteem by the emperor Charles V. For his services in his campaigns the emperor gave him considerable possessions in the Netherlands in 1522, and Francis I of France, who had occupied Orange, was compelled, when a prisoner in Madrid, to restore it to him. Philibert had no children, and he was succeeded by his nephew Réné of Nassau-Châlons, son of Philibert's sister Claudia and Henry, count of Nassau, the confidential friend and counsellor of Charles V. He too died without an heir in 1544 at the siege of St. Dizier, having devised all his titles and possessions to his first cousin William, the eldest son of William, count of Nassau-Dillenburg, who was the younger brother of Réné's father, and had inherited the German possessions of the family.

William of Orange-Nassau was but 11 years old when he succeeded to the principality. He was brought up at the court of Charles V and became famous in history as William the Silent (*q.v.*), the founder of the Dutch republic. On his assassination in 1584 he was succeeded by his eldest son, Philip William, who had been kidnapped by Philip II of Spain in his boyhood and brought up at Madrid. This prince never married, and on his death in 1618 his next brother, Maurice of Nassau (*q.v.*), stadtholder in the United Netherlands and one of the greatest generals of his time, became prince of Orange. Maurice died in 1625, also unmarried.

Frederick Henry, the son of Louise de Coligny, William's fourth wife, born just before his father's murder, now succeeded to the princedom of Orange and to all his brother s dignities, posts and property in the Netherlands. Frederick Henry was both a great general and statesman. His only son, William II (*q.v.*), was married in 1641 to Mary, princess royal of England, he being 15 and the princess 9 years old at that date, and he succeeded to the title of prince of Orange on his father's death in 1647. At the very outset of a promising career he suddenly succumbed to an attack of smallpox on Nov. 6, 1650, his son William III (*q.v.*) being born a week after his father's death.

A revolution now took place in the system of government in the united provinces, and the offices of stadtholder and captain- and admiral-general, held by four successive princes of Orange, were abolished. However, the counter revolution of 1672 called William III to the head of affairs. At this time Louis XIV conquered the principality of Orange and the territory was incorporated in France, the title alone being recognized by the treaty of Ryswick. For William III's accession to the throne of England, *see* ENGLISH HISTORY. He left no children, and a dispute arose among various claimants to the title of prince of Orange. The king of Prussia claimed it as the descendant of the eldest daughter of Frederick Henry; John William Friso of Nassau-Dietz claimed it as the descendant of John, the brother of William the Silent, and also of the second daughter of Frederick Henry. The result was that at the Peace of Utrecht in 1713, the king of Prussia aban-

doned the principality to the king of France in exchange for compensation elsewhere, and John William Friso gained the barren title and became William IV, prince of Orange. His sons, William V and William VI, succeeded him. William VI in 1815 became William I, king of the Netherlands (*q.v.*).

See Bastet, *Histoire de la ville et de la principauté d'Orange* (Orange, 1856). (G. E.)

ORANGE, a town of France, 18 mi. N. of Avignon on the P.L.M. railway. Pop. (1946) 13,978. Orange (*Arausio*), capital of the Cavari, was in 105 B.C. the scene of the defeat of a Roman army by the Cimbri and Teutones. It became after Caesar an important Roman colony. Its ramparts and fine buildings were partly destroyed by the Alamanni and Visigoths, and partly ruined by the erections of the middle ages. Orange was included in the kingdom of Austrasia, fell into the hands of the Saracens and was recovered by Charlemagne. It became the seat of an independent countship in the 11th century. The town had a university from the 14th century until the Revolution. Orange stands at some distance from the left bank of the Rhône, in the midst of meadows, orchards and mulberry plantations, watered by the Meyne, and overlooked by Mont Ventoux, 22 mi. to the east.

Orange has famous Roman remains. The triumphal arch ranks third in size and importance among those still extant in Europe; 72 ft. in height, 69 ft. in width, and 26 ft. in depth, it is composed of three arches supported by Corinthian columns. On three sides its sculptured decorations are well preserved. The arch seems to have been set up in honour of Tiberius, perhaps to commemorate his victory over the Gallic chieftain Sacrovir in A.D. 21. It was used as a donjon in the middle ages. The theatre, dating from the time of the emporer Hadrian and built against a hill on the summit of which a colossal figure of the Virgin stands, has a façade 121 ft. high, 340 ft. long and 13 ft. thick, which is pierced by three square gates surmounted by a range of blind arches and a double row of projecting corbels, with holes in which the poles of the awning were placed. Of the seats for the spectators, only the lower tiers remain. It was used as an outwork to the fortress built on the hill by Maurice of Nassau in 1622, and destroyed 50 years later by order of Louis XIV, who in 1660 captured the town. At the beginning of the 19th century it was filled with hovels and stables; the building has been cleared and restored, and now serves as a national theatre. Near the theatre traces have been found of a hippodrome; and there are statues, bas-reliefs and ruins of an amphitheatre. Notre Dame, the old cathedral, originally built by the prefect of Gaul, was ruined by the barbarians, rebuilt in the 11th and 12th centuries, and damaged by the Protestants.

There are manufactories of footwear, brooms, jewellery and beet sugar. The town deals largely in fruit, and millet stalks for brooms, as well as in wool, silk, honey and truffles.

ORANGE, a city of Orange county, Calif., U.S.A., 34 mi. S.E. of Los Angeles and 14 mi. from the Pacific ocean; served by the Pacific Electric, Santa Fe and Southern Pacific railways and Pacific Electric motorbuses. Pop. (1950) 10,027; (1940) 7,901 by the federal census. It is surrounded by orange and lemon groves. The average annual crop of citrus has a value of $20,000,000.

The city's industries include citrus and walnut packing houses and insulated copper wire, television antenna, twine, cordage, rope, machinery and gold-leaf manufacturers.

ORANGE, a town of Franklin county, Mass., U.S., on Millers river and the Boston and Maine railroad, 40 mi. N.W. of Worcester. Pop. (1950) 5,894; in 1940 it was 5,611. It has numerous and varied manufacturing industries.

The district of Orange was formed in 1783 from parts of Athol, Royalston and Warwick, and certain common lands, and in 1810 it was made a town.

ORANGE, a city of Essex county, N.J., U.S., 12 mi. W. of New York city, 4 mi. W. of Newark; served by the Erie and the Lackawanna railways, interurban trolleys and motorbus lines.

Pop. (1950) 38,037; (1940) 35,717 by the federal census. The city covers 2.2. sq.mi. at the base of the first Watchung mountain, in the heart of the great suburban residential community known as "the Oranges," completely surrounded by East, South and West Orange. There are approximately 90 manufacturing establishments in the city. The assessed valuation of property at mid-20th century exceeded $45,000,000. In 1914 the city adopted a commission form of government. Settlement began there soon after the founding of Newark in 1666, and the region was generally called Newark Mountain. In 1718 the people of "the mountain" severed connections with the church at Newark and formed an independent congregation. The neighbourhood was referred to as Orange Dale in 1782 and two years later Orange was in use. The township of Orange was set off from Newark and incorporated in 1806. It was incorporated as a town in 1860; the other Oranges were set off from it in 1861, 1862 and 1863; and in 1872 it was chartered as a city.

ORANGE, a city on the eastern boundary of Texas, U.S., at the head of navigation on the Sabine river; the county seat of Orange county. It is on federal highway 90; has an airport of 200 ac. and a 32-ft. channel which joins the city with the Gulf of Mexico; and is served by the Missouri Pacific and the Southern Pacific railways. The population was 21,174 in 1950 and 7,472 in 1940 by the federal census. The city is built around a deep hairpin bend in the river. It is surrounded by major gas and oil fields, huge forests of pine and cypress and a cultivated district devoted chiefly to rice farming, poultry and dairying. The port of Orange has facilities for accommodating all types of ocean-going vessels. Orange is headquarters of the Texas group, Atlantic reserve fleet. Industries include shipbuilding, kraft paper and paper bag manufacturing, creosoting, rice milling, industrial gas manufacturing, canning, lumber milling, woodworking, food processing and steel fabrication, and there are manufactures of nylon salts, methanol, adipic acid, ethylene-polythene plastics and other chemical intermediates. The city was founded as a trading post about 1600, and began expansion with the completion of harbour improvements in 1914 and the discovery of oil in 1920.

ORANGE, the longest river of South Africa, almost traversing the continent from ocean to ocean. It rises in Basutoland, less than 200 mi. from the Indian ocean, and flows west, with wide sweeps south and north, to the Atlantic. It drains, with its tributaries, an area estimated at more than 400,000 sq.mi., passing through more than twelve degrees of longitude or 750 mi. in a straight line from source to mouth. The valley of the river exceeds 1,000 mi., and the stream has a length of not less than 1,300 mi. Its headstreams are in the highest part of the Drakensberg range, the principal source, the Sinqu, rising, at an elevation of more than 10,000 ft., on the Mont aux Sources in 28° 48′ E., 28° 50′ S.

Rising on the inner slopes of the hills these rivulets all join the Sinqu, which receives from the north several streams which rise in the Maluti mountains. Of these the largest are the Semene and Sinqunyane (little Sinqu) and the best known the Maletsunyane, by reason of its magnificent waterfall—an unbroken leap of 630 ft. Increased by the perennial waters of these numerous torrents the Sinqu makes its way southwest across the upland valleys between the Maluti and Drakensberg ranges. After a course of some 200 mi., the Sinqu, already known as the Orange, receives the Makhaleng, or Kornet Spruit (90 mi.), which rises in Machacha mountain. The Orange here enters the great inner plateau of South Africa, which at Aliwal North, the first town of any size on the banks of the river, 80 mi. below the Kornet Spruit confluence, has an elevation of 4,300 ft. Forty miles lower down the Orange is joined by the first of its large tributaries the Caledon (230 mi.), which, rising on the western side of the Mont aux Sources, flows, first west and then south, through a broad and fertile valley. At the confluence the united stream has a width of 350 yd. Thirty miles lower down the Orange reaches, in 25° 40′ E., its southernmost point—30° 40′ S., approaching within 20 mi. of the Zuurberg range. In this part of its course the river receives from the south the streams, often intermittent, which rise on the northern slopes of the Stormberg, Zuurberg and Sneeuwberg ranges. Of these the chief are the Kraai, which joins the Orange near Aliwal North, the Stormberg and the Zeekoe (Sea Cow), the last named having a length of 120 mi.

From its most southern point the Orange turns sharply N.W. for

200 mi., when, having reached 29° 3′ S., 23° 36′ E., it is joined by its second great affluent, the Vaal (*q.v.*). There it bends south again, and with many a zigzag continues its general westerly direction, crossing the arid plains of Bechuana, Bushman and Namaqualands. Flowing between steep banks, considerably below the general level of the country, there about 3,000 ft., it receives, between the Vaal confluence and the Atlantic, a distance of more than 400 mi. in a direct line, no perennial tributary but on the contrary loses a great deal of its water by evaporation. In this region, nevertheless, skeleton river systems cover the country north and south. These usually dry, sandy beds, which on many maps appear rivers of imposing length, are deep and turbulent streams for a few hours or days following rare but violent thunderstorms.

In 28° 35′ S., 20° 20′ E., are the great waterfalls of the Orange, where in cataracts and cascades the river drops 400 ft. in 16 mi. The Aughrabies or Hundred falls, as they are called, are divided by ledges, reefs and islets, the last named often assuming fantastic shapes. Below the falls the river rushes through a rocky gorge, and openings in the cliffs to the water are rare. These openings are usually the sandy beds of dried-up or intermittent affluents, such as the Bak, Ham, Houm, Aub (or Great Fish) rivers of Great Namaqualand. Crossing the narrow coastal plain the river, with a southwesterly sweep, enters the ocean by a single mouth, studded with small islands, in 28° 37′ S., 16° 30′ E. A large sand bar obstructs the entrance to the river, which is not quite 1 mi. wide. The river when in flood, at which time it has a depth of 40 ft., scours a channel through the bar, but the Orange is at all times inaccessible to seagoing vessels. Above the bar it is navigable by small vessels for 30 or 40 mi.

Capt. Henry Hop first crossed the Orange in Sept. 1761, but shortly afterward returned. In 1777 Capt. (afterward Col.) R. J. Gordon, a Dutch officer of Scottish extraction, who commanded the garrison at Cape Town, reached the river in its middle course and named it the Orange in honour of the prince of Orange. Next year Lieut. W. Paterson, an English traveller, reached the river in its lower course, and in 1779 Paterson and Gordon journeyed along the west coast of the colony and explored the mouth of the river. F. Le Vaillant also visited the Orange near its mouth in 1784. Mission stations north of the Orange were established a few days later, and in 1813 the Rev. John Campbell, after visiting Griqualand West for the London Missionary society, traced the Harts river, and from its junction with the Vaal followed the latter stream to its confluence with the Orange, journeying thence by the banks of the Orange as far as Pella, in Little Namaqualand, discovering the great falls. These falls were in 1885 visited and described by G. A. Farini, from whom they received the name of the Hundred falls. The source of the Orange was first reached by the French Protestant missionaries T. Arbousset and F. Daumas in 1836.

The story of Hop's expedition is told in the *Nouvelle description du Cap de Bonne Espérance* (Amsterdam, 1778). Lieutenant Paterson gave his experiences in *A Narrative of Four Journeys into the Country of the Hottentots and Caffraria in the Years 1777–1778–1779* (London, 1789). *See* also Campbell, *Travels in South Africa* (London, 1815); Arbousset and Daumas, *Relation d'un voyage d'exploration au nord-est de la colonie du Cap de Bonne Espérance en 1836* (Paris, 1842); Farini, *Through the Kalahari Desert* (London, 1886).

ORANGE, several species of *Citrus* (family Rutaceae, subfamily Aurantioideae), the genus to which the lemon, grapefruit and lime also belong. The orange tree has shining broad evergreen leaves, fragrant white blossoms and nearly globose orange-coloured edible fruit. The species of orange most important commercially are the sweet or common orange (*C. sinensis*), the mandarin orange (*C. reticulata*), and the sour orange (*C. aurantium*). The species differ chiefly in shape, size, texture and flavour of fruit, and in tree characteristics.

The tree of the sweet orange (*Citrus sinensis*), which is also called the common or China orange, sometimes attains a height of 35 ft. Leaves are medium sized, ovate; petioles are less broadly winged than those of the sour orange. The pulp of the sweet orange is agreeably acidulous and sweet, the peel is comparatively smooth and the oil glands are convex. The usual shape of the sweet-orange fruit is round; certain varieties are greatly elongated; others are much flattened; several, *e.g.*, the Washington Navel, have a conical protuberance, the navel, at the apex.

The mandarin orange (*Citrus reticulata*), some varieties of which are called tangerines, was formerly classified as *C. nobilis*. Trees are smaller than those of sweet or sour orange; the twigs are slender and the leaves lanceolate. The fruits are depressed subglobose, with very thin loose peel easily separated from the segments and bright orange colour when ripe. Some varieties, especially the tangerines, are decidedly reddish tinted; the segments are readily separated from each other. The flavour is mild and pleasing. Some varieties, such as the Satsuma, are seedless.

The sour orange, also called the Seville, bigarade or bitter orange (*Citrus aurantium*), is a rather small tree, rarely exceeding 25 ft. in height. The green shoots bear sharp axillary thorns; leaves alternate, ovate, pointed at the tip, with margins entire or very slightly serrated; colour a glossy dark green; petioles more broadly winged than those of the sweet orange, articulated with the leaf. Fruits are subglobose, slightly depressed at both ends, sometimes nippled at apex; fruit surface is rough, dotted closely with concave oil glands; colour at maturity is brilliant orange with slight reddish tint; the pulp is only moderately juicy, relatively low in sugar and thus decidedly acid-flavoured (3.5% to 4.5% acid); seeds are numerous.

These three species of orange reproduce themselves true to type, in most cases, by seed; and, where hybridizing is prevented, the seedlings of the sweet, mandarin and sour oranges retain the more distinctive features of their respective parent plants.

History.—There is some doubt as to the place of origin of the orange. Though the orange is now the most widely cultivated of *Citrus* species and is grown in most of the warmer parts of the world, its diffusion has taken place in comparatively recent historical periods. To ancient Mediterranean agriculture the orange was unknown, although the later Greeks and Romans were familiar with the citron (*Citrus medica*) as an exotic fruit. The careful research of G. Gallesio indicated that India was the country from which the orange spread to western Asia and eventually to Europe. Oranges are found apparently wild in the jungles along the lower mountain slopes of parts of northern India. This fact, however, is only a partial proof that they originated there. Oranges and other citrus species have escaped from cultivation in several parts of the world, such as Florida, South Africa and Argentina; having thrived in the wild state, they have sometimes been erroneously considered indigenous. The wild plants are generally thorny, and present the other characters of the sour orange, but occasionally wild oranges occur with sweet fruit; it is, however, doubtful whether either the sweet or the sour species is really indigenous to Hindustan, and Alphonse de Candolle is probably correct in regarding south China and the Indochinese peninsula as the original home of the orange. Cultivated from a remote period in southeastern Asia, the orange was carried to southwestern Asia by the Arabs, probably before the 9th century, toward the close of which the sour orange (*C. aurantium*) seems to have been well known to that people; though, according to Masudi, it was not cultivated in Arabia until the beginning of the 10th century, when it was first planted in Oman, and afterward carried to Mesopotamia and Syria. It spread ultimately, through the agency of the same race, to Africa and Spain, and perhaps to Sicily, following everywhere the tide of Mohammedan conquest and civilization. In the 12th century the sour orange was abundantly cultivated in all the eastern Mediterranean countries, and the returning crusaders brought it from Palestine to Italy and southeastern France.

In Florida the sour orange has grown from an unknown period, in a wild state; but it seems certain that this orange was brought by the Spanish colonists to the West Indies and was transplanted to Florida soon after the first settlement, in 1565. The chief use of the sour orange in the western hemisphere is for rootstocks on which to graft sweet orange and other *Citrus* species.

There is no allusion to the sweet orange in European literature contemporary with the crusades, and the introduction of this fruit into Europe took place at a considerably later period, though

the exact time is unknown. The sweet orange was commonly cultivated in Italy early in the 16th century, and seems to have been known there previous to the expedition of Vasco da Gama (1497), as a Florentine narrator of that voyage appears to have been familiar with the fruit. The importation of this tree into Europe is usually attributed to the Portuguese, who first circumnavigated Africa and found the way to India and China, although Gallesio suspects that Genoese merchants of the 15th century, who must have found it growing abundantly then in the eastern Mediterranean region, may have introduced it.

The mandarin orange (*Citrus reticulata*), a native of southern China, was not introduced into Europe until after mediaeval times, even though it was known and extensively planted in China and Japan as early as the 12th century. Throughout China and in Japan, oranges have been grown from very ancient times, and they were found diffused widely when the East Indian archipelago was first visited by Europeans.

Cultivation.—Oranges are not strictly tropical plants and they thrive best where the trees are chilled somewhat by occasional slight night frosts in winter. The trees are semidormant at that season, and temperatures as low as 30° to 28° F. will not harm trees or fruits unless frost occurs early, before the trees have finished their annual growth. On the coldest sites, some means of heating the orchards is resorted to in California, and, to a lesser degree, in Florida. In such cases the critical temperature is 26° F. In California, the usual practice is to burn petroleum oil in small 5- to 8-gal.-capacity heaters (40 to 50 per acre); in Florida, pine or oak wood is the most widely used fuel.

The orange thrives in a wide range of soil conditions, from extremely sandy soils to rather heavy clay loams; it grows especially well in the intermediate types of soil. Orange orchards are generally planted in relatively deep soil where drainage is good. The orange trees are usually budded on stocks grown from the seed of selected trees of mandarin, sour or sweet orange, or the so-called Rough lemon. The seeds are sown in well-prepared soil in a lath house; after about 12 months' growth there, the seedlings are removed to a nursery. After 12 to 16 months in the nursery, the trees, then about ⅜ in. in diameter at a distance 6 in. above the ground, are usually large enough to bud. When the budded tops are one to two years old, the trees are large enough to plant in the orchard. The number of trees planted per acre in the United States ranges from 80 to 110, depending upon vigour and variety and upon the method of culture to be followed.

The ground between the young, newly planted trees is often used for vegetable crops such as beans, tomatoes or melons, the choice depending upon the market demand for such annual crops. The culture of intercrops helps to provide favourable conditions for the young orange trees for the first five or six years, until they reach the age of profitable production; after this, the entire land is usually devoted to the orchard. The growth of cover crops during the winter months in California, and during the summer months in Florida, prevents erosion damage and makes use of the seasonal rainfall for the production of organic matter to be incorporated into the soil. In addition to this organic material, it is essential to use relatively large amounts of fertilizers, such as various nitrogenous materials; in Florida, applications of phosphate and potash are essential. Some of the minor nutritional elements, especially zinc, copper, manganese and magnesium, are frequently lacking in citrus soils, and small applications are then necessary. In many areas where oranges are grown, it is necessary to supplement the rainfall with irrigation; this is generally the practice in California, Texas, Palestine, Spain, Morocco and in parts of South Africa. In the 18th century the orange tree became a favourite object of conservatory growth in England; in the open air, in protected locations, it has often stood the cold of many seasons in the southern counties and has occasionally borne abundant fruit. The orange has usually been cultivated in England for the beauty of the plant and the fragrance of the blossoms, however, rather than for the supply of edible fruit.

In garden culture in southern Europe, the orange is sometimes trained as an espalier, and with careful attention yields fruit in great profusion when thus grown. Orange trees will continue to bear abundantly from 50 to 80 years or even more, and some old orange trees, whose age must be reckoned by centuries, still produce crops; these very ancient trees are generally of the sour orange, and have probably been frozen back and then rejuvenated by sprouts from near the ground. Sweet-orange trees growing under orchard conditions occasionally acquire a considerable size; a 67-year-old sweet-orange tree near Pasadena, Calif., had a spread of 36½ ft.; its height was 33 ft.; its circumference, 1 ft. above ground, was 5 ft. 7 in.

Harvesting and Packing.—Oranges are picked when fully ripe for, unlike some deciduous fruits, they do not ripen or improve in quality after being picked. In the United States it is unlawful to sell oranges until they have reached a certain state of maturity, determined by the ratio of total soluble solids to acids in the fruit juice. In California, the fruit must attain a maturity ratio of soluble solids to acids of 8:1 before it may be lawfully sold. As 80% to 85% of the soluble materials are sugars, and citric acid is the principle which gives oranges the typical mildly acid flavour, this ratio is often erroneously spoken of as the sugar-to-acid ratio. In some sections oranges can be left on the trees for 5 to 6 months after they become mature enough to eat; during this period the sugars increase and the acids decrease, so that the ratio of soluble solids to acids at the end of the picking season is sometimes as high as 17:1. The vitamin content of oranges declines as the fruit becomes overmature.

Oranges are carefully handled during the picking and packing operations to prevent them from being punctured, scratched, bruised or scarred by abrasions. This care is necessary to prevent losses from decay caused by various moulds, such as blue mould and other fungus organisms, which are widely distributed. The normal unbroken surface of the peel of the orange is very resistant to such diseases, but they readily gain entrance to the very susceptible inner portion of the peel and to the pulp of the fruit if the surface of the peel is injured even in the most minute way. To prevent such injury, and to prevent scarring of the fruit by the fingernails, oranges are picked by well-trained workmen wearing cloth gloves. The orange is removed from the twig by clipping the stem as close to the fruit as is practicable. By this care in handling, which is somewhat comparable to the handling of eggs, millions of dollars worth of fruit is saved which would otherwise be lost by decay.

As the oranges pass through the packing house, they are handled largely by machinery, from the time the field boxes are dumped until the fruit is finally ready for packing in the shipping boxes. The following is an example of the usual processes through which the fruit goes in the packing house. It is (1) doused in hot soapy water (115° F.); (2) cleaned as it passes under revolving brushes; (3) rinsed in clear water and brushed simultaneously; (4) rinsed in water and borax solution; (5) rinsed in clear water; (6) dried by passing on a belt conveyor through a tunnel through which air is forced at a high velocity; (7) culled by hand as it passes over a belt conveyor; (8) graded for size; and (9) wrapped in tissue paper and packed by hand. In California many packing houses use supplementary aids, such as nitrogen trichloride gas or other fungicides or disinfectants, to prevent decay. A very thin layer of wax is applied to most oranges to prevent undue drying in transit or in the market. In the United States, oranges are packed in wooden boxes for shipment, California boxes holding approximately 77 lb. of fruit, and Florida boxes holding approximately 90 lb. Each box is packed with the same sized fruit throughout. A medium-sized orange is 2¾ in. in diameter and packs 176 to a California box.

Varieties.—In 1943 H. J. Webber described 97 varieties of sweet and mandarin oranges, which had been grown in the various subtropical parts of the world. Of the sweet oranges, the Washington Navel is the principal winter variety grown in California and Arizona, and the Valencia is the principal summer variety grown in these areas. The principal sweet varieties grown in Florida are: Hamlin, Pineapple, Parson Brown, Homosassa and Valencia. In Texas, the cultivation of the Valencia and Hamlin varieties increased greatly in the decade 1940–50. Blood oranges form another group of sweet oranges. They are char-

acterized by the deep-red tint of the pulp, and comprise some of the best varieties; they are grown extensively in the Mediterranean region, but have not become popular in the U.S.

The mandarin oranges, which include the tangerines, are grown more extensively in Florida than elsewhere in the United States; the variety most widely grown is the Dancy tangerine. The Temple, a loose-, thin-skinned fruit, especially desirable at one time in Florida, appears to be a hybrid between the mandarin and the sweet orange. Another loose-skinned type of orange, of the mandarin group, is the Satsuma, which was introduced into the United States in 1876 from Japan, where it is widely grown. The Satsumas ripen earlier in the fall and are more resistant to frost than other commercially grown citrus fruit. They have been rather extensively grown in certain areas bordering the Gulf of Mexico, where it is too cold for the production of sweet oranges; but freezes during the two decades 1922–42 greatly reduced the acreage. Mandarin oranges are highly prized as dessert fruits because of their attractive appearance and because their loose skin and easily separable segments make them easy to handle. The mandarins are lower in vitamin C content than are sweet oranges, lemons or grapefruit.

The sour orange is grown to some extent in all citrus-producing sections, but its production on a commercial scale has been mainly limited to southern Spain, where it was first planted years ago by the Moorish conquerors. The most important commercial use of the fruit is in the manufacture of marmalade. The sour orange in general is too acid and bitter for use as a fresh fruit; the juice, however, has a distinctive flavour which makes it a pleasing addition to certain beverages. The fruits are also used in making confections, liqueurs (curaçao) and other drinks. The fruit and leaves are used in making a number of medicinal preparations, and the flowers, leaves and fruits yield volatile oils (bigarade oils) of characteristic odour, much prized for perfumes. The oranges of the bergamot group (subspecies *Citrus bergamia*) are largely grown in southern Italy and Sicily for the essential oil which is expressed from the peel for making perfume. The bergamot group is thought to be of hybrid origin, with the sour orange as one of the parent species.

Diseases and Insect Pests.—Several diseases, of fungus or virus origin, are generally distributed over most of the subtropical areas where oranges are grown. One of the most troublesome of these diseases, brown-rot gummosis or foot rot, is caused by several species of fungi (*Phytophthora* species). This disease affects the lower trunk and the crown roots of the tree, and also produces a brown rot on the fruit, while it is still on the trees, in those years when weather is especially damp during the picking season. *Phytophthora* decays also cause loss of picked fruit. Spray mixtures in which copper is the lethal element are commonly used to spray the lower part of the tree, as the splashing of the rain spreads the fungus spores most readily to the low-hanging fruits. When the disease is present on the crown roots and trunk, the tree has a devitalized appearance characterized by poor growth, pale small leaves and more than the normal amount of dead twigs. The affected crown has dark-coloured areas from which gum exudes; beneath these areas the cambium is dead and discoloured. If not cut out and disinfected, the diseased areas continue to enlarge and finally girdle the tree. Preventive measures consist in avoiding both too deep planting and excessive water next to the trunk. The most devastating virus disease is quick decline, also known as *tristeza* in South America. It is spread by propagating from diseased trees and also by two species of aphids. As the name implies trees are killed suddenly by this disease. Another virus disease of oranges is psorosis, formerly called scaly bark in California. Seriously affected trees become valueless. The disease is spread largely by propagating from diseased trees, and may be avoided by care in selecting healthy trees from which to take buds.

Loss of fruit in storage and transit is caused by rots produced by *Phytophthora* species, green mould (*Penicillium digitatum*), blue mould (*P. italicum*), black rot (*Alternaria citri*) and others. Loss from these diseases is greatly reduced by the care exercised in handling the fruit during picking and packing.

The insect pests most commonly troublesome to oranges in California are five species of scale: black scale (*Saissetia oleae*), yellow scale (*Aonidiella citrina*), purple scale (*Lepidosaphes beckii*), red scale (*Aonidiella aurantii*) and citricola scale (*Coccus pseudomagnoliarum*). Several species of mealy bugs cause damage in particular cases and during some seasons, but, because of their insect parasites, they are not so generally harmful as the scale insects. In some districts in California, the citrus thrips (*Scirtothrips citri*) is a serious pest.

The citrus red mite or red spider (*Paratetranychus citri*), as well as aphids and other insects, causes damage in the coastal and intermediate areas if not controlled by insecticides. Other pests which are especially important are the Mexican fruit fly (*Anastrepha ludens*) in Texas and the citrus rust mite (*Phyllocoptes oleivorus*), citrus white fly (*Dialeurodes citri*), Florida red scale (*Chrysomphalus aonidum*) and also purple scale (*Lepidosaphes beckii*) in Florida. The control of insect pests in all citrus-producing areas is one of the most difficult and expensive factors in the commercial production of oranges.

One of the serious pests of oranges is the Mediterranean fruit fly (*Ceratitis capitata*), wherever it occurs in subtropical areas of the world. The fly lays its eggs in the peel of the fruit, and the larvae develop in the pulp. An infestation was found in Florida in the spring of 1929, but by late fall of 1930 it had been successfully exterminated, at an immense cost to the state and federal governments. With the exception of the mealy bugs, most of the insect pests, as well as the various mites, are usually controlled satisfactorily by spraying or dusting. These very effective operations are highly mechanized. The spray and dusting rigs are mounted on trucks or hauled by tractors. Dusting or mist spraying may also be done from an aeroplane. In one of the spray materials most commonly used, petroleum oil is the principal toxic agent. Highly refined, light-medium or medium oil emulsions applied at concentrations of $1\frac{1}{2}\%$ to 2%, mixed with water, are most in use. To the mixture an additional toxic material, such as rotenone or pyrethrum, is often added to increase the effectiveness of the spray. Lime-sulphur sprays, as well as sulphur applied as a dust, are important insecticides, especially for thrips and red mites. Other dust materials used as insecticides are some of the organic compounds, such as dinitro-o-cyclohexylphenol, which are especially toxic to red mites. Nicotine sulphate as a spray or a dust is used for aphid control (*The Citrus Industry*, vol. 2, 1948).

Production and Consumption.—The sweet orange and the mandarin orange are the principal species produced commercially in the following countries, listed in approximate order of importance: in 1951–52, the United States, Spain, Brazil, Italy, Argentina, Japan, Mexico, Algeria and Egypt. The world production of oranges, of these and other countries, ranges from the equivalent of 250,000,000 to 329,000,000 boxes (70 lb. net each) annually. This enormous production of oranges, in comparison with that of other citrus fruits, is evidence of their world-wide popularity. Florida, California, Texas and Arizona are the principal producing states in that order. The mandarin oranges are produced more extensively in Florida than in any other area of the U.S.

Prior to 1920 the orange was considered principally as a dessert fruit for winter use. The drinking of orange juice, in contrast with the eating of the fresh fruit, was a major factor in the increase in per capita consumption. Another important factor was the increase in knowledge, gained in this period throughout the whole world, of the dietary value of all citrus fruit. One of the primary reasons for the important dietary value of oranges is their high vitamin C content, which averages 54 mg. per 100 g. of juice. Of the other fruits and of the vegetables commonly constituting a part of the human diet, only the lemon exceeds the orange in vitamin C content.

The most important product made from oranges is concentrated juice. During 1952–53, frozen concentrated juice required 30.1% of the crop to produce 51,815,000 gal. of concentrate. Essential oils, pectin, candied peel and orange marmalade are among the important by-products. Stock feed is made from the waste material left from the processing of some of the aforemen-

tioned articles. This dried residue, known as orange meal, compares favourably with beet pulp and other semiconcentrates used as stock feeds and conditioners in preparing cattle for market. The wood of the orange tree is of a fine yellow tint; it is hard and close grained and is valued by the turner and the cabinetmaker for the manufacture of small articles.

ORANGE, COUNCILS OF: *see* COUNCILS OF ORANGE.

ORANGEBURG, a city of South Carolina, U.S., the county seat of Orangeburg county; on the North Edisto river and federal highways 21, 178 and 301, at an altitude of 259 ft., 45 mi. S.E. of Columbia. It is served by the Atlantic Coast Line and the Southern railways. The population in 1950 was 15,322; in 1940 it was 10,521 by the federal census.

Orangeburg is the financial, commercial and industrial centre of a rich section of the Atlantic coastal plain, and is the seat of Claflin university (1869; Negro) and South Carolina State Agricultural and Mechanical college (1896; Negro). Cotton, grain, livestock, poultry, tobacco and pecans are leading products of the county, and the city has manufacturing industries. It operates under a commission form of government. In 1704 a trader and trapper built his cabin there, and in 1735 a colony of Germans and Swiss established a settlement, naming it in honour of William, prince of Orange. The town was incorporated in 1851 and was chartered as a city in 1883.

ORANGE FREE STATE, an inland province of the Union of South Africa. It is divided from Natal by the Drakensberg, from Basutoland by the Caledon river, from the Transvaal by the Vaal river and from the Cape Province by the Orange river and, in the west, by a line drawn across the veld from the Orange to the Vaal. It lies between latitudes 26° 30′ and 30° 40′ S. and between longitudes 24° 10′ and 29° 40′ E. Area, 49,647 sq.mi.

The country forms part of the inner plateau of South Africa, and most of it lies between 4,000 and 5,000 ft. above sea level. From the mountainous eastern districts it slopes gradually westward, no natural boundary marking its western frontier. The aspect of the country is that of vast, undulating, treeless plains, with a certain number of willows and thorn trees along the streams. The latter were formerly more widely spread but have nearly all been cut down for fuel. The Australian black wattle, gums and the pepper tree have been successfully introduced and are grown along the streets of the towns and in plantations on farms, especially in the eastern districts, to provide shelter, poles and firewood.

The general level of the surface is broken by low ridges and isolated table mountains, the latter attaining considerable elevation above the plain. They are particularly numerous and well developed in the east and are caused by the outcrop of beds of sandstones and dolerites. The rivers, except the Orange, Vaal and Caledon, are dry or nearly dry for three or four months during the dry winter season; but after rain even the small spruits may become raging torrents. (For geology, climate, flora and fauna, *see* SOUTH AFRICA, UNION OF.) (R. U. S.)

HISTORY

At the beginning of the 19th century the great plateau between the Vaal, the Orange and the Drakensberg mountains was a no man's land, and the passes over the Drakensberg the haunt of cannibals and assassins. The indigenous tribal structure, mainly Bechuana, had been broken by refugee Zulu impis that attacked and despoiled one another in the wilderness that they created. Matiwane between 1818 and 1829 ravaged the whole of the territory, annihilated Mpanazita at Mekwatleng (20 mi. N. of Ladybrand) and scattered the remnants of his tribe from the Vaal to Queenstown. Pursued by Shaka's impis, he fled across the Orange. His forces harried Pondoland but, mistaken for Shaka's, were dispersed by an expedition from the Cape. Equally formidable was the young Sikonyela and his mother Mantatisi, the amazon and witch who guided the last stand of the Batlokua.

There seem to have been only two stable focal points in the area. Immediately north of the Orange river, on both sides of the Vaal (in the Campbell lands; in the modern Griqualand West; and round Philippolis between the Orange and the Riet) there were contiguous Griqua settlements, protected by the formidable John Philip and encouraged by the government at the Cape as a buffer against incursions from the north. The Griqua frontiers fluctuated with their power, which, as they were the only people north of the Orange armed with rifles and as they were used to commando tactics, was greater than their numbers (*see* GRIQUALAND EAST AND GRIQUALAND WEST). The second nebular state was to the east, where, on the rocky slopes of the Drakensberg, Moshesh (Msheshwe) had rallied shattered groups of Bechuana and was forging the Basuto nation. Within his fortress kraal at Thaba Bosigo he had an impregnable refuge from which he defied Sikonyela and even the great Zulu Mzilikazi (Mosilikatze). Patron of missionaries, chiefly French, gifted not only with military skill but also with Machiavellian astuteness, Moshesh held out between Mzilikazi and a horde of lesser chiefs on the west and Dingaan across the mountains to the east. When times were favourable, his family with their followers diffused over the fertile Caledon plains and peacefully surrounded the territories of minor rivals. Moshesh used tribal structure as the basis of a new diplomacy at a time when the whole political geography of the Transorangia was fluid and chaotic.

In the 1830s systematic penetration of the lands across the Orange river began from the south. Missionaries, mainly Wesleyan in the west and Paris evangelicals in the east, embarked on a double and often rival program of conversion and settlement for displaced tribal groups. But even earlier than the Griqua settlement (1803) and the missionary penetration, a new kind of infiltration had begun, also from the south. Hunters and explorers had reported that there were great uninhabited plains north of the Orange river and fertile soil in the Caledon area. The Trek-Boers, ever questing after new pastures and new land to farm, began seasonal grazing across the Orange and then, by what they defined as grant and purchase (though often there was no written deed), procured lands from the Griquas or squatted in the Caledon area. Thus, while the Cape government strove to make a stable frontier at the Fish river, the frontier became increasingly an administrative myth. Then, in 1835, Lord Glenelg advised Sir Benjamin d'Urban to abandon the newly annexed province of Queen Adelaide, and the retraction of the frontier was the signal for the Great Trek (*see* CAPE PROVINCE). North of the Orange river the cautious probing of the Trek-Boers was engulfed in the exodus of about 2,000 frontier folk, mainly Boers, lured by the prospect of more land and impelled by resentment against British colonial policy in the Cape. It was the beginning of an invasion and revolution that altered the structure and to a great extent determined the future development of Transorangia.

The trekkers were assisted by the Barolong chief Moroka at Thaba Nchu, and it is said that, until his death, A. H. Potgieter was the friend of the Barolong. After initial reverses the trekkers mapped out and planned a republic, but dissensions led to a forking of their enterprise. While a core remained in the Winburg region, one branch pushed north across the Vaal and another, under Potgieter and Piet Retief, crossed the Drakensberg into Zululand and Natal (*qq.v.*). After the massacre of Retief's party, the Natal trekkers made a treaty with Panda, who overthrew his brother Dingaan and rewarded them with the cession of most of Natal, then denuded of inhabitants by the flight of the victims of the Zulu wars. There the trekkers organized a republic with its capital at Pietermaritzburg. Exiled tribes flocking back perturbed the trekkers, whose proposal to resettle them south of Natal in territory flanking Pondoland threatened a shunting movement that would have reacted on the frontier structure of the Eastern province. Though a philanthropic native policy was one of their objectives, it was probably this threat and, above all, commercial interests that induced the British to annex Natal in 1843. This, coupled with the announcement that there would be no colour bar in Natal and with the British attempt to resettle displaced Zulus there, determined many trekkers to abandon Natal

as they had abandoned the Cape. The Boers recrossed the Drakensberg and concentrated, some across the Vaal and some at Winburg. Thus Winburg in 1843 as in 1837 was the axis of Boer republicanism. In the same way, for different reasons, Transorangia became the axial point of British colonial policy.

Legally the attitude of the British government was based on the Cape of Good Hope Punishment act, passed in 1836 to extend criminal jurisdiction to all British subjects as far north as latitude 25° S. In political terms, this meant that the emigrants were not considered to have shed their allegiance by shaking the dust of the colony off their feet. Such, however, was the sole object of a resolute body of the trekkers; and men like Andries Pretorius, who abandoned ten farms in Natal to struggle back across the Drakensberg, made desperate sacrifices for their ideals. But British policy also had ideals, namely the controlled sale of crown lands so that some were held in trusteeship, the protection and civilization of native peoples and the extension of democratic institutions in areas of consolidated white settlement. The principles of British policy, especially in the "hungry forties," were crippled by lack of financial resources and by the interplay of crosscurrents of opinion on a disintegrated party structure in Great Britain. Ill-informed but sincere and powerful missionary interests in England demanded ever more protection for natives, while the equal eloquence of the Manchester school of economists demanded retrenchment and reform. In the swirl a policy coherent in principle was often impotent, sometimes mischievous in practice. Logically the annexation of Natal should have been preceded by the annexation of Transorangia. Instead the period 1837–48 was a disastrous interregnum which helped to jeopardize the experimental annexation between 1848 and 1854.

Between 1837 and 1848 the British fumbled to find means of enforcing the Punishment act and stabilizing native territories without incurring the responsibilities of sovereignty. In 1843 the Napier treaties with Adam Kok III (allied since 1838 to Waterboer) and with Moshesh tried to fix frontiers and tenures which in fact ignored Boer claims as well as the claims of minor chieftains in the centre. The signatories were to enforce the Punishment act. This led to armed protest from the Boers and almost consolidated a Boer front against Great Britain, until armed clash was followed in June 1845 by the Maitland treaties at Touwfontein. These planned to divide native lands into two: an inalienable tribal block; and lands which could be leased, the quitrents from which were to be divided between the chief and the expenses of a British resident to be established in the territory. This was a step forward; but many Boers had already purchased land outright, the frontiers claimed by Adam Kok were dubious, and Moshesh, who claimed inalienable sovereignty over lands wherever his people had fought or planted, was systematically surrounding the lesser chiefs between the Basutos and the Griquas with Basuto settlers. Inevitably the treaties failed to give stability or security. Though H. D. Warden was installed as resident at Bloemfontein, he had no white garrison in the whole of the area. More and more Boers relied on private enterprise, indifferently co-ordinated by Winburg.

When in Dec. 1847 Sir Henry Smith was made governor of the Cape and high commissioner for South Africa, it seemed as if the problem of South Africa was to be treated as a whole and no longer in segments. He had vigour and popularity and, up to the limits allowed by the colonial office, the courage of his convictions. He rounded off the seventh Kaffir war by annexing the Stormberg area and Kaffraria to the Cape; he speeded up the land commission in Natal with consideration for Boer demands there; and, after a tour that included an interview with Andries Pretorius at the Tugela Drifts, he annexed Transorangia to the crown and in Feb. 1848 proclaimed the Orange River sovereignty.

The Orange River Sovereignty, 1848–54.—Between 1848 and 1854 Great Britain sought to evolve an effective policy that would satisfy all groups at home and give firm ground to all in the quicksands of the new sovereignty. On frontier policy, all settlers on the fringes tended to think alike, whether Boer, Scots or English, so that a local patriotism independent of racial or political theory tended to crystallize at Bloemfontein as it had done in the Eastern province. When the annexation was proclaimed, because it seemed to promise security it was on the whole welcome to the majority of the white settlers. The Boer settlers seem to have fallen into two groups (apart from an indeterminate and scattered number of pioneers, who were not politicians) the pre-Great Trek settlers and loyalists; and the minority of irreconcilables, concentrated mainly in the Winburg area, who were moved by almost religious conviction that the theory of British policy was wrong and that their spiritual freedom lay in their political extrication from its clutches. It was this Winburg section that summoned Pretorius from Magaliesburg to lead revolt. To make that revolt successful, negotiations were conducted not only with Moshesh but with Panda, their former ally.

Such a tactic, if successful, would have exposed the whole of the sovereignty to the ravages of Zulu impis. The means could neither have justified nor served the end. More, extremists like Willelm Jacobs and Gert Kruger resolved at Winburg (Feb. 1848) to punish with fine, confiscation and death Boers who refused to cooperate. Many who joined the revolt did so because of compulsion; others claimed that they had thought an armed remonstrance was all that was intended; Potgieter sent no assistance from Ohrigstad across the Vaal. Pretorius and his party, having evicted British officials from Winburg, drove the embryo administration out of Bloemfontein and across the Orange, while loyalist Boers went into laager. When troops were available, Smith made a leisurely crossing of the Orange and advanced until attacked by Pretorius at Boomplaats (Aug. 1848). A vigorous skirmish of three hours culminated with the withdrawal of Pretorius across the Vaal with a price on his head. Two rebels taken in arms were shot and fines were levied, but there was no wholesale policy of total eviction. In the Cape, the children of Pretorius kept their extensive farms. Boomplaats, which was later to assume a distorted significance, cleared the air at the time; and when in Jan. 1852 the Sand River convention with Pretorius secured the Klip river and Harrismith to the sovereignty, it was possible for the latter to develop as a distinct geographical and political entity.

The Orange River sovereignty was divided into four administrative districts, Bloemfontein, Smithfield (Caledon River), Winburg and Harrismith. Each was equipped with a minimum official staff, but only Bloemfontein maintained a garrison. The colonists were responsible under their field cornets for their own defense. Quitrents and traders' licences were the main source of the sovereignty's revenue. There was a central legislative council, nominated but two-thirds burgher. There was, however, no burgher representation on the executive until July 1853. Thus the official government tended to get out of touch with burgher sentiment when it sought to tackle the land question. In the 20th century the plan of administration would be described as one of reciprocal *apartheid:* the native chiefs were to remain undisturbed within surveyed frontiers, while their "foreign relations" one with another were subject to British control; they were otherwise to be "self-governing" through tribal structure, which, however, it was hoped would be modified by missionary guidance. But this ambitious policy could not be enforced by an understaffed administration. Moroka and Sikonyela and other minor chiefs, supported in some cases by their several missionaries, contested the frontiers claimed by Moshesh and his missionaries. No less than six frontiers were proposed to edge the Basuto lands off, and the Warden line (1849) satisfied no one—least of all the white settlers, because it cut through the fertile Caledon farming area. Bickering led to a series of local wars in the course of which Moshesh smashed his rivals (including Sikonyela). The administration was helpless, as the burghers were reluctant in disturbed times to abandon their farms for commando duty to enforce a policy of delimitation that, though it gave them full legal title to their farms, ran contrary to their traditions.

Given time, resources and sympathy, a solution was, though difficult, not inconceivable in the sovereignty. Warden laid the foundation stone of the Dutch Reformed church in Bloemfontein in 1849 and that of St. Andrew's cathedral in 1850. Settlers both Boer and British were trickling in, together with a sprinkling of foreign immigrants. The *Friend of the Sovereignty* was be-

ing printed in both Dutch and English. Special Commissioners W. S. Hogge and Mostyn Owen, who had sponsored Transvaal independence, could urge that the case of the sovereignty was different and that its evacuation would be a betrayal of responsibility. But like Earl Grey, his counterpart at the colonial office, Sir George Cathcart, who became high commissioner on Sir Henry Smith's recall in March 1852, was bent on withdrawal after an abortive attack on and defeat by Moshesh at the Berea (Dec. 1852). In Sept. 1853 Sir George Clerk arrived with special powers to "settle and adjust the affairs of the Sovereignty." This was a euphemism for abandonment, a decision which the spectacle of Moshesh's private wars served to harden. A convention, elected on universal manhood suffrage, refused to vote itself into a republic. A public subscription raised enough to send the Rev. Andrew Murray and A. J. Fraser to England to protest against abandonment. Before they arrived in England, the die was cast. Clerk began importing supporters from the Transvaal to cabal for the negation of British policy in the sovereignty. A contrived assembly accepted the convention of Bloemfontein, which thrust independence on what was now the Free State, in Feb. 1854. Ten months later, Sir George Grey arrived in South Africa as high commissioner, a year too late to save the sovereignty. Great Britain abandoned not only the sovereignty but also all existing treaties with native states north of the Orange river, save only those with Adam Kok. Clerk undertook to "establish affairs in Griqualand," but neither then nor in 1861 (when Kok sold the remnants of his land to the Free State) were the Griqua lands defined.

The Orange Free State to 1900.—The constitution devised by the burghers in April 1854 was a blend of traditional Boer institutions with U.S. and Dutch constitutional theory. The unicameral *volksraad* had parliamentary sovereignty with control over taxation and over legislation and the right to ratify treaties and to declare war. No constitutional change could be made without a three-quarter majority in favour in each of two succeeding annual sessions (in 1885 the high court was given power to decide whether a law was against the constitution). Franchise depended on the possession of burgher rights, which were limited to adult male Europeans, qualified either by birth or by property or by residence. Executive power was vested in a president and an executive council. The president was elected by direct vote of qualified burghers for five years and was eligible for re-election. Roman Dutch law was declared the law of the land, Dutch the official language. Equality before the law, freedom of association and freedom of the press were among the rights secured to burghers. The Dutch Reformed Church was to be promoted by the *volksraad*. Local government and defense turned on the traditional election of field cornets and all burghers were liable for commando duty. The judicial structure, central and local, and the provision of municipal boards followed the Cape pattern. The constitution was liberal and worked well. The small quorum of 12, however, tended at times to let power slip into the hands of an inner circle; but as new districts were created and controversial issues were raised, burghers in the outlying areas, who had at first regarded the constitution as a superfluous addition to the Ten Commandments, took a more active part in politics (since, moreover, the representative structure of single-member constituencies was related not to population but to districts, a small town like Hoopstad with 30 voters came by the end of the century to have as much weight as a large city like Bloemfontein).

Until 1871, and to a certain extent throughout its existence, the Free State had the same problems that the sovereignty had had. The southern area looked to the Cape for its commerce and was influenced by Cape traditions, while the eastern and northern parts were dependent on the Harrismith route to Natal and had even closer links with the Transvaal—a cleavage corresponding to that between the Winburg and the sovereignty men. But wise leadership and the facing of common dangers welded the Free State for a time into what James Bryce defined with confidence as a model state.

The first president was J. H. Hoffman (1854–55), chosen for his reputed ability to cope with Moshesh; but his diplomatic present of a keg of gunpowder to the chief raised the outcry that forced him to resign. He was followed by the *voortrekker* J. N. Boshoff, formerly secretary to the Natal *raad*. M. W. Pretorius, of Potchefstroom, heir to the Winburg policy of his father Andries, tried by a coup at Rhenoster river (1857) to force the alignment of the Free State with Potchefstroom (Transvaal), but force was met by force and in June peace was made between the two republics, through whose histories, however, the idea of fusion was to run like a theme. Peace was timely, for Moshesh had seized the opportunity to pounce again. A bold Free State move against Thaba Bosigo failed so completely that Boshoff appealed both to Pretorius and to Grey, and the *volksraad* passed a resolution in favour of confederation with the Cape. Grey, convinced that the conventions had been a blunder because it was bad strategy to handle the native question piecemeal, responded by arbitrating the first treaty of Aliwal North (Sept. 1858) on the basis of adjusting the Warden line to give the Basuto more land in the Caledon area. This made explicit what the convention of Bloemfontein had evaded, namely that the western frontier of Basutoland marched with the eastern frontier of the Free State, and neither state had jurisdiction over the lands of the other.

Thereafter constant encroachments on both sides led to outrages, murder and undeclared war. The issues were complicated by Basuto family and tribal politics. Moshesh's sons Molapo and Masupha favoured a forward policy that Moshesh professed, perhaps insincerely (*cf.* his proven intrigues with native chiefs in the northern Cape and Pondoland), to eschew. Not the least subtle part of Moshesh's propaganda was the insinuation that the Boers in the Free State were the common enemy of the Basuto and the British. With the Cape government in difficulties in the Transkei and the Transvaal disunited and menaced on two fronts, Moshesh awaited the attack that he had provoked.

The third president of the Free State, M. W. Pretorius (1859–63), who for a short time combined the presidencies of the Free State and of the Transvaal, achieved a brilliant coup when, in 1861, he purchased the lands of Adam Kok III, the Griqua, for £4,000, albeit on ambiguous terms (*see* below). But Pretorius found that he could not keep his grip on the Free State without forfeiting his position in the Transvaal and resigned the presidency of the Free State in 1863, to be succeeded by J. H. Brand.

President Brand (1864–88) declared war on Moshesh in 1865. When the Free State forces were victorious (a belated Transvaal commando did little more than rescue for itself the lion's share of the booty), Moshesh played his last card and bestowed Basutoland as a Greek gift on Queen Victoria; but meanwhile he had accepted the treaty of Thaba Bosigo, which gave the Free State half his land. The Free State, however, was too weak to enforce the treaty, and guerrilla war was resumed. In March 1868 Sir Philip Wodehouse annexed Basutoland. Brand protested vigorously, but farmers who tried to move in on their allotted farms were often unable to hold them against Basuto raiders; and in safer zones those who had no share of the spoils protested that speculators in the new lands depressed land values in the old. Moreover, in the southwest of the Free State, the frontier resulting from Pretorius' Griqua purchase still needed definition. In 1869, then, Brand signed the second treaty of Aliwal North, which reiterated the convention of 1854 and drew a final frontier between the Free State and Basutoland, by which a substantial portion of the conquered territories remained to the Free State. The *volksraad* ratified the treaty with one dissentient, even though it cut off a possible outlet to the sea via Pondoland.

On the whole, by 1868, though coin was short and credit low, the Free State had made remarkable progress. The Grey college, nucleus of the future university, had been founded, churches were established and municipal boards created. The resources of the state were greater than its assets, for it had steadily extended its land. The new Basutoland frontier left the bulk of the wheatlands to the Free State. Most of the native enclaves were in the process of disintegration, partly because of the early wars of Moshesh, partly because of European purchase and diplomacy. In marked contrast to practice in the Cape and Natal, native ownership was forbidden, while only two substantial reserves, at Thaba

Nchu and at Witzieshoek, were destined to survive under Free State protection.

Even before he had resolved the Basutoland crisis Brand found himself involved in the ambiguities of Pretorius' Griqualand purchase. Adam Kok denied from the first that the purchase included the Campbell lands which Cornelis Kok had bequeathed to him. More vociferously, Waterboer, in Griqualand West, claimed that, whatever his intentions, Adam Kok had had no power to sell them or Cornelis any right to bequeath them, since he, Cornelis, held the lands merely as vassal of Waterboer. The Campbell lands sprawled across both sides of the Vaal river, the eastern portion having in practice been administered by Warden from Bloemfontein and by the Free State from Jacobsdal. Quite apart from the claims of Waterboer, the British high commissioner was anxious to secure either for Great Britain or for the Cape the missionary-merchant road to the north; the Transvaal coveted most of the land west of the Vaal between the Langeberg mountains and the Molopo river; and the Free State could advance a common-sense claim to land in the angle of the Vaal and Orange rivers to reinforce its interpretation of the purchase of 1861.

The discovery of diamonds, first on both sides of the Vaal river and then in the dry diggings (1870), sharpened the conflict and made a leisurely solution impossible. There was the immediate problem of jurisdiction over the congested cosmopolitan diggings; there was the problem of controlling native and coloured vagrants and labourers, who flocked from every quarter; there was the question of trade and transport development; and there was the question of the ownership of the diggings, which was now tossed like an apple of discord by Waterboer to Great Britain. The British government made two separate but not unrelated decisions: to enforce the Keate award (1871) against the Transvaal (*q.v.*); and to annex Griqualand West. To the Free State this could only seem peremptory and, as evidence which was not brought forward until after the annexation suggested, unjust.

In 1876 Brand visited London on the invitation of the secretary of state for the colonies, the earl of Carnarvon. Understandably, the Free State was at that point averse to schemes of federation, and Brand took no part in the discussions of them. He did, however, secure £90,000 in compensation; and the Free State was promised a further £15,000 if a railway linked either with the growing Cape system or with the Natal line were completed in five years. The compensation had the present advantage of liquidating the public debts of the Free State. The blow was further softened by the discovery of diamonds at Koffiefontein (1875) and at Jagersfontein (1878), well within the state boundaries. The Free State was no longer terra incognita, but a busy highway to the diamond fields and a transport riders' paradise. Frontier security as well as the leaven of relative prosperity stimulated farming. It was during this diamond decade that, as a result of the work of J. Brebner, the first inspector general of education, the sound foundations of a general system of primary education were laid.

Brand saw more clearly than most of his contemporaries the importance of railways; he also perceived the sound strategic position of his state in the economic development of the hinterland, especially when the Rand gold rush succeeded the Lydenburg (*see* TRANSVAAL throughout). But he also understood the temper of the Free State and how to make haste slowly. His first Railway bill was introduced in 1876. Thereafter, for 12 years it was a hardy annual. Brand's patience, imperturbability and concern for his people, which won and held their confidence, stood him in good stead during the sustained crisis of the first British annexation of the Transvaal (1877–81) and the climax at Majuba, where he mediated between the belligerents. He was troubled during the last decade of his presidency by the renaissance of old cleavages in a new guise. The pressure of the Afrikander Bond emphasized the divergences of the two white races. The political strategy of Paulus Kruger in the Transvaal was a more formidable version of the policy of Pretorius and aimed at building an exclusive republican axis against both the Cape and Natal. A growing minority in the Free State favoured the Delagoa bay railway policy of Kruger, whereas Brand had to consider not merely the unity of his state as a political entity but also the geographical, economic and cultural links with the Cape. Brand worked unceasingly for the closer co-operation of the four white communities but was not prepared to make the Free State the footstool of any one of them. For him the immediate problem was that of railway construction, to which the whole question of transit rates and of customs duties at the ports was allied. An understanding in clause viii of the convention of Bloemfontein that the Cape would allow a customs rebate on goods in transit to the Free State had, for reasons of Cape finance and parochial politics, not been fulfilled. Brand therefore prepared the ground for a customs agreement with the Cape, from which in the next decade the Free State was to reap substantial rebates. One week before his death, he secured the belated approval of the *volksraad* for the extension of the Cape railway system to Bloemfontein. Even then it was only secured because the chairman, Sir John Fraser, used his casting vote. Opinion in the Free State, never well-informed on economic issues but instinctively averse to the cosmopolitan commercialism of the new era, was falling back on the trekker tradition of occlusiveness. Old antagonisms revived, nourished on inbred misunderstandings now made manifest in the conflict between the South Africa of Kruger's dreams and the South Africa of Cecil Rhodes' calculations.

During the presidencies of F. W. Reitz (1889–95) and of M. T. Steyn (1896–1900) a metamorphosis took place in Free State politics and opinion. From one point of view this was but a local example of tendencies current in contemporary Europe, namely the basing of political loyalties on racial ties. From the Free State point of view, it was the revival of old traditions to meet new challenges. Frontier security, increased profits and greater literacy tended to give farmers in the outlying districts leisure for politics and to revel in the propaganda of the Bond with its program of an Afrikander renaissance. Conflict between Transvaal and Cape economic interests, even earlier than conflict between the Transvaal and Great Britain, tended to split Free State opinion. The determinant, though, was the policy of Kruger in the Transvaal. His object was to secure an alliance or, if necessary, a federal as distinct from an incorporating union with the Free State. The alliance was concluded by Reitz in March 1889 and ratified by the *volksraad*. At first the implications which Fraser and Barlow had foreseen were not apparent. The customs union with the Cape was fulfilled. In 1892 the Natal-Harrismith line was completed. In 1893 the first train from Cape Town to Pretoria crossed the Free State, while the line from Kimberley to Mafeking and the north skirted the Free State on the west. For the first time the economic integration of southern Africa was possible. But the drifts crisis and then the Jameson raid (Dec. 1895) inflamed public opinion, and the year 1896 opened with Free State commandos manning the frontiers, prepared and even anxious to assist President Kruger in the Transvaal.

For the Free State, the raid was a psychological shock and a political blunder. M. T. Steyn was elected president in Feb. 1896 on the crest of a wave of pro-Transvaal sentiment, though the opposition candidate, Fraser, knew that even before the raid his chances had been slender. Thenceforward, as the crisis in the Transvaal mounted, while still counselling moderation almost to the end, Steyn, with a clear majority behind him, kept both lines open in theory but so strengthened the links with the Transvaal that the legal obligations of the Free State government reflected the instinct and opinion of the majority. Steyn's move to introduce a referendum with its connotation of popular sovereignty failed; but the qualifications for obtaining burgher rights were stiffened, the arming of commandos was brought into line with Transvaal practice and equipment and a commission was appointed to study federal union with a view to bringing the legal structure of both states to move on parallel lines. Several Free Staters, among them Gregorowski and former President Reitz, entered the service of the Transvaal. Steyn urged Kruger to accept any compromise that would avert war without actually injuring the Transvaal and strove for peace at the Bloemfontein conference of May-June 1899 and for conciliation even after the ultimatum of October; but the Free State's refusal to accept the

British offer of neutrality turned not on diplomacy but on the conviction that, once the issue was joined, moral obligation determined conduct. (For the events of the war *see* SOUTH AFRICAN WAR and SOUTH AFRICA, UNION OF.)

The Orange River Colony (May 1900–May 1910).—Lord Roberts occupied Bloemfontein in March 1900; and on May 28 the Free State was annexed by Great Britain as the Orange River colony. For two more years Generals Christian de Wet and J. B. M. Hertzog blazed the commando trail in the Cape until definitive peace was concluded at Vereeniging on May 31, 1902, when British sovereignty was acknowledged. In June that year a nominated legislative council was set up and on this prominent burghers served as unofficial members. "It would take the pen of a Joshua and a Jeremiah," wrote Jan Christiaan Smuts, "to picture the condition of the Free State": it was a picture the more shocking in that, in spite of native wars, South Africa had never before experienced total war between equal contestants. Farms were denuded of crop and stock, fences were down, houses in ruin. It is true that by grant and loan much was done to accelerate recovery and to lay new foundations. For Bloemfontein an extension to the power station and new waterworks at Mazelspoort made civic development possible; but even as late as 1904 the yield of wheat and of wool and the number of cattle were strikingly less than they had been before the war. A reconstruction loan in 1903 led to the establishing of 556 new settlers, but even Viscount Milner's administrative genius could not with the stroke of a pen restore the ravaged veld.

By 1904 two groups, the nationalist Orangia Unie and the so-called Constitutional group led by Fraser and Barlow, were agitating for constitutional government. The latter group had the ear of the British Liberal party, which was returned to office at the end of 1905. The change in government in Great Britain meant a fresh approach to South African affairs.

Lord Selborne, who had already replaced Milner as high commissioner and governor of the Transvaal and of the Orange River colony, was retained, and the intercolonial conferences, begun with those on native affairs and education, were continued; but the granting of the promised self-government was expedited. In July 1907 royal letters patent conferred full responsible government on the Orange River colony, and the first postwar election was held in Nov. 1907.

Sir H. J. Goold-Adams, hitherto lieutenant governor of the colony, now became governor; his relationship to the new parliament was defined by well-established conventions such as had been observed, in the Cape for instance, since 1872. Of 38 seats in the new parliament, the Orangia Unie won 29. A. Fischer was prime minister, General Hertzog attorney general and minister of education, Cornelius Wessels commissioner of public works and General de Wet minister of agriculture. It was an able if somewhat uneasy team, whose task had been greatly simplified by five years' postwar economic rehabilitation. But the British administration was to reap where it had sown. In 1902 men like Brebner and Ryk de Villiers had been purged from the state service; in 1908 the new anglophile bureaucracy was in its turn winnowed.

Under Milner's administration education had been made free, compulsory and nonsectarian and the whole structure of the schools had been altered; but administration had been ruthlessly centralized, and English had become the medium of instruction, while the reliance in the main on English-speaking teachers meant that little use could be made of the five hours allocated to the teaching of the Dutch language, since the teachers did not understand it. It was to meet this situation that voluntary Christian National schools were founded.

When the colony was granted self-government, the pendulum swung back. While denouncing the Dutch Reformed Church, which he accused of "setting up a papacy in every village," Hertzog allowed dogmatic instruction in the schools; and while theoretically allowing for parallel dual medium instruction where numbers warranted, in practice he made Dutch increasingly the medium of instruction, so that by 1910 English children were being withdrawn into private schools. For Hertzog was a passionate devotee of Afrikander culture and claimed, understandably if inaccurately, that it had made the Free State.

The chief constructive work of the cabinet was continued participation in intercolonial consultation, notably the customs and railway conference of 1908 and full and constructive participation in the national convention (*see* SOUTH AFRICA, UNION OF) which began in Oct. 1908. The outstanding personality from the Orange River colony was former President Steyn, who was conspicuously successful as a mediator and who secured that the future appeal court of the Union should sit at Bloemfontein, which was to become the judicial capital of the proposed Union. The bill for union was passed simultaneously by the parliaments of each of the four colonies and was enacted, in the form then submitted, by the imperial parliament in 1910, and the colony entered the Union under the style of Orange Free State province.

The Province of the Orange Free State.—The new Free State, like the other provinces, preserved historical continuity by retaining its entity as a province. Like Natal, it was to send 25 members to the house of assembly in Cape Town; and from the time when Fischer and Hertzog entered the first Union cabinet, Free State members, conspicuously Hertzog and N. J. van der Merwe (1880–1940), played an important role as leaders of a compact phalanx.

It was from the Free State that the revolt of De Wet in 1914 drew its main strength; and the province followed two successive leaders of Afrikander nationalism, namely Hertzog and D. F. Malan. In the election of 1953, all 25 seats, including for the first time Bloemfontein city, were won by the Nationalist party. In some ways the Redistribution act of 1952 accentuated certain anomalies, since 81,329 votes were sufficient to return 25 Nationalists, whereas the 31,647 votes cast for the United party (25% of the total poll) were swamped. (W. A. ML.)

POPULATION, ADMINISTRATION AND ECONOMY

Population.—The population of the Orange Free State amounted to 1,018,207 according to the census of 1951. The total comprised 775,702 Africans, 227,587 Europeans and 14,069 others (mainly persons of mixed blood but including 16 Asians) and constituted 12.4% of the total population of the Union of South Africa. The average density was 20.5 per square mile. The major concentrations are in the eastern and better-watered districts. The towns are mostly small administrative and provisioning centres for their surrounding districts. Bloemfontein (the capital of the province and the axis of the Union's road, rail and air communications), Kroonstad, Ladybrand, Harrismith and Ficksburg are described in separate articles. Bethlehem is a prosperous centre in the northeast. Parys (population 8,103, including 3,906 Europeans, in 1951), on the Vaal river, is a pleasure resort.

The largest element of the African population is constituted by the southern Sotho (Basuto), who are scattered widely over the province. A considerable number of Tswana (Bechuana) live in the district of Thaba Nchu; the Zulu are well represented, chiefly in the northeastern area adjoining Zululand; and the Xosa are numerous in the southern and western districts. As a result mainly of the historical development of the Free State and of the trekkers' policy of defeat and dispersal of the African populations, only about 26,000 of the total number of Africans in the province live in the reserves of Witzieshoek and of Thaba Nchu (the latter was impressively rehabilitated by the Union native affairs department); the rest are either in urban locations or squatters on European farms. Little has been done to purchase more land in terms of the Native Land Trust act; and surveys such as the Fagan report (1948) make it clear that to provide land in the Free State for Africans more than 25 times as numerous as those already in reserves is impossible. Nor is land available in adjacent Basutoland, where the movement of migration is outward, not inward, and where the direction of labour, because of working conditions and wages, is from agriculture to industry.

Administration.—The provincial council of 25 elected members meets under the presidency of the administrator who is nominated by the governor general. Members hold office for five years. A provincial ordinance has effect so long as it is not re-

pugnant to an act of parliament, and it must have the assent of the governor general in council (since the governor general acts constitutionally on the advice of his ministry this may lead to oblique control of the provinces by the ministry of the day). Provincial powers are mainly defined by sections 85–91 of the South Africa act together with the Financial Relations Consolidation act of 1945. Provincial ordinances deal mainly with local affairs, such as hospitals, roads, etc.

Education, other than higher, has been the main field of provincial initiative. The South Africa act secured equal rights for both Dutch and English languages. An act of the Union parliament in 1912 stipulated that in the lower standards the medium of instruction should be in the home language of the pupils; but provinces differ in their administrative definition of home language, and the Free State still bears the impress of Hertzog's educational policy. In 1920 the Free State was the first province to sponsor the substitution of Afrikaans for Dutch, anticipating Union policy by six years.

The province is divided into 57 school districts, in each of which is an advisory board consisting of elected members and having certain powers of supervision. In 1950 there were 375 primary and secondary schools for Europeans (with 45,902 pupils) and 569 primary and secondary schools for non-Europeans (with 74,000 pupils). In 1953 the Eiselen report proposed that, since provincial finance was inadequate to meet the cost of native education, native education should be extricated, as was native policy, from provincial control and put under the administrative as well as the financial control of the Union.

Agriculture and Stock Raising.—The most fertile part of the country lies in the valley of the Caledon river. There a considerable quantity of wheat is grown, especially in the districts of Ladybrand, Ficksburg, Bethlehem and Rouxville. The same districts and Harrismith also produce oathay. There, too, are extensive apple and plum orchards, the apples being among the best grown in South Africa. Potatoes, tobacco, pumpkins, etc., are also grown. The province's most important crop, however, is maize, the districts of Heilbron and Frankfort, in the north, forming part of the South African maize belt (toward the west the area sown with maize varies greatly from year to year, according to the incidence of the rains). The Free State produces more than one-third of the Union's maize crop and might even treble its yield through a better use of fertilizers.

The country is also healthy for livestock. It is little affected by horse sickness and the number of horses in 1950 was 217,578. Cattle, numbering 1,981,518 in 1950, are most numerous in the eastern districts, especially about Ficksburg. Woolled sheep, totalling 6,594,060 in 1951, are most abundant in the Rouxville, Wepener and Smithfield districts, while goats (34,035) are either kept by natives or concentrated in the dry southwestern area about Philippolis.

Mining and Industry.—The discovery of gold fields in the Odendaalsrust area, where the Welkom and St. Helena mines began production in 1952, seemed likely to transform the industrial structure of the province. In all of the seven developing mines, moreover, the production of uranium oxide from residue ore after gold extraction was authorized. The proximity of the field to the power station at Viljoensdrift suggested that the Free State might indeed be on the edge of an industrial revolution.

The province's output of diamonds amounted to 140,357.75 carats in 1951. Diamonds are found around Jagersfontein (the chief mine) and Koffiefontein in the southwest, around Boshof in the west, around Theunissen toward the centre of the province and around Kroonstad; and alluvial diamonds of great purity occur in the gravels of the Vaal and some of its tributaries. About 3,370,000 tons of coal were produced in 1951, the chief collieries being the Cornelia on the Vaal opposite Vereeniging and the Clydesdale 15 mi. S.; but the coal is not of the best quality. Salt is obtained from the waters of certain "pans" in the western districts, evaporated in most cases by solar heat.

The construction of grain elevators and the opening of mills and of creameries fostered subsidiary industrial enterprises. The census of industrial undertakings for 1946 (published in 1949), while confirming that the Free State was the least industrialized of the four provinces, showed an increasing variety of such undertakings on an increasing scale. (R. U. S.; W. A. Ml.)

ORANGEMEN. In 1795, after a violent conflict between Protestants and Roman Catholics in County Armagh, Ireland, known as the battle of the Diamond, a Protestant Orange society, called after William of Orange, was formed "to maintain the laws and peace of the country and the Protestant constitution." The Orange society spread its branches, called lodges, and by 1797 it had about 200,000 members. It was joined by many of the gentry and it counteracted the influence of the United Irishmen, particularly in Ulster. During the early and middle years of the 19th century the movement fell into some obscurity and disrepute; but when Gladstone declared in favour of Irish home rule in 1885, the Orange order, as it came to be called, provided a core of resistance. The order had a great influx of new members, especially in Ulster. Through the controversies which followed, it provided both a means of expression and a restraining discipline for many Unionists. The membership in Ulster at mid-20th century contained a large proportion of farmers and skilled workers and a good many professional men, and there were lodges for women. The ethical obligations of membership are high. The movement is also active in Glasgow, Liverpool, Toronto, Ont., and many other places, but the social background and ethos of the movement are somewhat different outside Ulster. July 12, the anniversary of the battle of the Boyne, is celebrated by Orangemen each year. (Hu. S.)

ORANGUTAN ("man of the woods"), the giant red manlike ape of Borneo and Sumatra (*Pongo pygmaeus*). The reddish colour of the long, coarse hair distinguishes the mias, as the Dyaks call it, from African apes; the arms are such that the animal in the upright posture can rest on its bent knuckles. In some races, in the old males, which may stand 5½ ft. high, there is a large expansion of the cheeks, caused by growth of fibrous tissue and producing a broad and flattened type of face. Another peculiarity of the males is the presence of a huge throat sac on the front of the throat and chest, which may extend even to the armpits; although present in females, it does not reach nearly the same dimensions in that sex. More than half a dozen separate races of orangutan are recognized in Borneo where the red ape inhabits the swampy forest tract at the foot of the mountains. These apes are comparatively slow and deliberate in their movements; they construct platforms of boughs in the trees, which are used as sleeping places, apparently occupied for several nights in succession. Durian, the tough spiny hide of which is torn open with their strong fingers, forms their chief food. They also eat the mangustin and other fruits. (*See* Primates.)

ORANIENBAUM, renamed Lomonosov after World War II, a city of the Russian S.F.S.R. in the Leningrad oblast, in 59° 54′ N., 29° 48′ E., lying 100 ft. above the sea on the south coast of the Gulf of Finland, opposite Kronstadt. Pop. (1926) 7,061. It was formerly a summer residence of the imperial family. The site was given to Menshikov in 1714 by Peter the Great, and the palace he erected still stands. Confiscated in 1727, it became an imperial residence. In 1743 the empress Elizabeth presented Oranienbaum to the future Tsar Peter III, who built there a castle, now destroyed, for his Holstein soldiers. The palace became a hospital during World War I, and was later made a rest home for workers. A school of forestry was established in one of the wings. A railway was built to link the town with the fort of Krasnaya Gorka, standing guard at the entrance to Kronstadt bay. There were established flour mills and brickworks, the sawmilling industry also being important.

ORAON, an aboriginal tribe of the Chota Nagpur plateau, India, also known as Dhangars. They call themselves *Kurukh,* but being divided into various groups are apt to be designated by

group names (*e.g.*, Modi, "navvy," Kisan, "cultivator") when they emigrate. A short, sturdy race of Dravidian type, they are in demand as labourers. As Oraon mothers shape their babies' heads their dolichocephaly may be to some extent artificial. The village organization is advanced. Their speech is akin to Kanarese. Their religion is a mixture of nature worship and magic, thinly overlaid with Hinduism, Dharmes being the supreme god.

A religious movement, influenced by Christianity as well as by Brahmanism, known as the Tana Bhagat movement and manifesting itself in ghost hunting and the addition of German Baba to the pantheon, caused some excitement in 1915. It had begun with a crusade against belief in ghosts and was largely a revolt against social degradation and economic depression.

See Sarat Chandra Roy, *The Oraons of Chota Nagpur Ranchi* (1915), for a full history and valuable information; *Man in India,* I (1921).

ORATOR, one who speaks in public, especially an eloquent public speaker. *See* RHETORIC and separate articles on eminent orators, such as DEMOSTHENES; ISOCRATES; etc.

A statesman of modern times, Sir Winston Churchill, won international acclaim for his effective oratory. His skill and power as an orator were recognized by the Swedish academy, which announced on Oct. 15, 1953, that Churchill had received the Nobel prize for literature not only for his historical and biographical works but also for "the scintillating oratory in which he has stood forth as a defender of eternal human value." It was the first time that oratory had been cited as the partial basis for the Nobel award in literature.

The term also refers to an officer of the universities of Cambridge and Oxford, the orator speaking in the name of, as well as on behalf of, the university on various public and special occasions.

ORATORIO, the name given to a form of religious music with chorus, solo voices and orchestra, independent of, or at least separable from the liturgy, and on a larger scale than the cantata (*q.v.*). Its history is involved in that of opera (*see* ARIA and OPERA), but its antecedents are more definite. The term is almost certainly (but *see* Schütz's "stilo Oratorio" on p. 844) derived from the fact that St. Filippo Neri's Oratory was the place for which Animuccia's settings of the *Laudi Spirituali* were written; and the custom of interspersing these hymns among liturgical or other forms of the recitation of a Biblical story is one of several origins of modern oratorio. A more ancient source is the use of incidental music in miracle plays and in such dramatic processions as the 12th century *Prose de l'Âne,* which on Jan. 1, celebrated at Beauvais the Flight into Egypt. But the most ancient origin of all is the Roman Catholic rite of reciting, during Holy Week, the story of the Passion according to the Four Gospels, assigning the words of the Evangelist to a tenor, distributing all *ipsissima verba* among appropriate voices, and giving the *responsa turbae,* or utterances of the whole body of disciples (*e.g.*, "Lord, is it I?") and of crowds, to a chorus. The only portion of this scheme that concerned composers was the *responsa turbae,* to which it was permitted to add polyphonic settings of the Seven Last Words or the eucharistic utterances of the Saviour. The narrative and the parts of single speakers were sung in the Gregorian tones appointed in the liturgy. Thus the settings of the Passion by Victoria and Soriano represent a perfect solution of the art-problem of oratorio. "Very tame Jews" is Mendelssohn's comment on the 16th century settings of "Crucify Him"; and it has been argued that Soriano's and Victoria's aim was not to imitate the infuriated Jews, but to express the contrition of devout Christians telling the story. On the other hand, ancient tradition ordained a noisy scraping of feet on the stone floor to indicate the departure from the place of the judgment seat! And so we owe the central forms of Bach's Lutheran Passion-oratorios to the Roman Catholic ritual for Holy Week.

With the monodic revolution at the outset of the 17th century the history of oratorio as an art-form wholly controlled by composers begins. There is nothing but its religious subject to distinguish the first oratorio, Emilio del Cavalieri's *Rappresentazione di anima e di corpo* from the first opera, Peri's *Euridice,* both produced in 1600. Differentiation was brought about primarily by the fact that oratorios without stage-presentation gave opportunity for a revival of choral music. And oratorios on the stage discouraged, by reason of their sacred subjects, whatever vestiges of dramatic realism could survive the ascendancy of the aria (*q.v.*). For lesser composers than Bach and Handel this ubiquitous form represented almost the only possibility of keeping music alive, or at least embalmed, until the advent of the dramatic and sonata styles. The efforts of Carissimi (d. 1674) in oratorio clearly show how limited a divergence from the method of opera was possible when music was first emancipated from the stage. Yet his art shows the corruption of Church music by a secular style rather than the rise of Biblical music-drama to the dignity of Church music. Normal Italian oratorio remains indistinguishable from serious Italian opera as late as *La Betulia liberata,* which Mozart wrote at the age of 15. Handel's *La Resurrezzione* and *Il Trionfo del Tempo* contain many pieces simultaneously used in his operas, and they contain no chorus beyond a perfunctory operatic final tune. *Il Trionfo del Tempo* was a typical morality play, and it became a masque, like *Acis and Galatea* and *Semele,* when Handel at the close of his life adapted it to an English translation with several choral and solo interpolations from other works. Yet between these two versions of the same work lies half the history of classical oratorio. The rest lies in the German Passion-oratorios that culminate in Bach; after which the greatest music avoids every form of oratorio until the two main streams, sadly silted up, and never afterwards quite pure, unite in Mendelssohn.

Luther was so musical that while the German Reformation was far from conservative of ancient liturgy, it retained almost everything which makes for musical coherence in a Church service; unlike the English Church, which with all its insistence on historic continuity, so rearranged the liturgy that no possible music for an English Church service can ever form a coherent whole. The four *Passions* and the *Historia der Auferstehung Christi* of H. Schütz (who was born in 1585, exactly a century before Bach) are as truly the descendants of Victoria's Passions as they are the ancestors of Bach's. They are Protestant in their use of the vulgar tongue, and narrative and dialogue are set to free composition instead of Gregorian chant, although written in Gregorian notation. The *Marcus Passion* is in a weaker and more modern style and stereotyped in its recitative. It may be spurious. But in the other Passions, and most of all in the *Auferstehung,* the recitative is a unique and wonderful language. It may have been accompanied by the organ, though the Passions contain no hint of accompaniment at all. In the *Auferstehung* the Evangelist is accompanied by four viole da gamba in preference to the organ. The players are requested to "execute appropriate runs or passages" during the sustained chords. A final non-scriptural short chorus on a chorale-tune is Schütz's only foreshadowing of the contemplative and hymnal element of later Passion oratorios.

The *Auferstehung,* the richest and most advanced of all Schütz's works, has one strange convention, in that single persons, other than the Evangelist, are frequently represented by more than one voice. If this were confined to the part of the Saviour, it would have shown a reverent avoidance of impersonation, as in Roman Catholic polyphonic settings of the Seven Words. But Schütz writes thus only in *Die Auferstehung* and there on no particular plan. While the three holy women and the two angels in the scene at the tomb are represented naturally by three and two imitative voices, Mary Magdalene is elsewhere always represented by two sopranos.

Shortly before Bach, Passion oratorios were represented by several remarkable works of art, most notably by R. Keiser (1673–1739). Chorale-tunes, mostly in plain harmony, were freely interspersed in order that the congregation might take part in what was, after all, a church service for Holy Week. The meditations of Christendom on each incident of the story were expressed in accompanied recitatives (*arioso*) leading to arias or choruses, and the scriptural narrative was sung to dramatic recitative and ejaculatory chorus on the ancient Roman plan. On slightly different lines was Graun's beautiful *Tod Jesu,* which was famous when the contemporary works of Bach were ignored.

The difference between Bach's Passions and all others is simply the measure of his greatness. Where his chorus represents the

whole body of Christendom it has as peculiar an epic power as it is dramatic where it represents tersely the *responsa turbae* of the narrative.

In the Matthew Passion the part of Christ has a special accompaniment of sustained strings, generally at a high pitch, though deepening at the most solemn moments. And at the words "Eli, Eli, lama sabacthani" this musical halo has vanished. In power of declamation Bach was anticipated by Keiser; but no one approached him in sustained inspiration and architectonic greatness. The forms of Passion music may be found in many of Bach's Church cantatas; a favourite type being the *Dialogue*; as, for instance, a dispute between a fearing and a trusting soul with, perhaps, the voice of the Saviour heard from a distance; or a dialogue between Christ and the Church, on the lines of the Song of Solomon. The Christmas Oratorio, a set of six Church cantatas for performance on separate days, treats the Bible story in the same way as the Passions, with a larger proportion of non-dramatic numbers. Many of the single Church cantatas are called oratorios, a term which by Bach's time seems definitely to have implied dialogue, possibly on the strength of a false etymology. Thus Schütz inscribes a monodic sacred piece "in stilo Oratorio," meaning "in the style of recitative." The further history of oratorio radiates from the heterogeneous works of Handel.

There are various types and several mixtures of style in Handelian oratorio. The German forms of Passion music evidently interested Handel, and it was after he came to England, and before his first English oratorio, that he set to music the famous poetic version of the Passion by Brockes, which had been adopted by all the German composers of the time, and which, with very necessary improvements of taste, was largely drawn upon by Bach for the text of his Johannes-Passion. Handel's Brockes Passion does not appear ever to have been performed, though Bach found access to it and made a careful copy; so Handel must have composed it for his own edification. He soon discovered that many kinds of oratorio were possible. The emancipation from the stage admitted of subjects ranging from semi-dramatic histories, like those of *Saul, Esther* and *Belshazzar,* to cosmic schemes expressed entirely in the words of the Bible, such as *Israel in Egypt* and *The Messiah.* Between these types there is every gradation of form and subject; besides an abrupt contrast of literary merit between the mutilated Milton of *Samson* and the amazing absurdities of *Susannah.*

The very name of Handel's first English oratorio, *Esther,* and the facts of its primary purpose as a masque and the origin of its libretto in Racine, show the transition from the stage to the Church; and, on the other hand, Haman's lamentation on his downfall is scandalously adapted from the most sacred part of the Brockes Passion.

We may roughly distinguish three main types of Handelian oratorio, not always maintained singly in whole works, but always available as methods. First, there is the operatic method, in which the arias and recitatives are the utterances of characters in the story, while the chorus is a crowd of Israelites, Babylonians or Romans (*e.g., Athalia, Belshazzar, Saul,* etc.). The second method retains the dramatic rôles both in solos and in choruses, but (as, for instance, in "Envy, eldest born of Hell," in *Saul*) also uses the chorus as the voice of universal Christendom. Handel's audience demanded plenty of arias, most of which are accounted for by futile, when not apocryphal, love affairs. The haughty Merab and the gentle Michal are characterized with fatal ease, and make parts of *Saul* almost as impossible as most of *Susannah.* The third Handelian method is a series of choruses and numbers on a subject altogether beyond the scope of drama, as, for instance, the greater part of *Solomon* and, in the case of *The Messiah* and *Israel in Egypt,* treated entirely in the words of Scripture, and those not in narrative but in prophecy and psalm.

After Bach and Handel, oratorio fell upon evil days. The rise of the sonata style, which brought life to opera, was bad for oratorio; since not only did it accentuate the fashionable dislike of that polyphony which is essential even to mere euphony in choral writing, but its dramatic power became more and more disturbing to the epic treatment that oratorio naturally demands.

Philip Emanuel Bach's oratorios, though cloying in their softness and sweetness, achieved a true balance of style in the earlier days of the conflict; indeed, a judicious selection from *Die Israeliten in Wüste* (1769) would perhaps bear revival almost as well as Haydn's *Tobias* (1774).

The Creation (*Die Schöpfung*) and *The Seasons* (*Die Jahreszeiten*) will always convey to unspoilt music-lovers the profound message of the veteran Haydn, who could not help "worshipping God with a cheerful heart." This spirit was well known to Bach, the composer of *"Mein glaübiges Herze,"* and it is compatible with the romantic sound-pictures and Handelian sublimity of the opening Representation of Chaos and the great chord of C major at the words "and there was light." The childlike gaiety of much of the rest ought not to blind us to its fundamental greatness, which brings the naïvely realistic birds and beasts of *The Creation* into line with even the wine-chorus in the mainly secular *Seasons,* and removes Haydn from the influence of the vile taste which henceforth pervaded oratorios, until Mendelssohn effected a partial improvement. Haydn strenuously resisted the persuasion to undertake *The Seasons* which had a close connection with Thomson's poem, as *The Creation* had a distant connection with *Paradise Lost.* He thought the whole scheme "Philistine" (his own word) and, both before he yielded to persuasion and after he had finished the work, said all the hard things about it that have ever been said since.

Roman Catholic oratorio was under the disadvantage that it was not permitted to take Biblical texts except in the Latin language. Jomelli's *Passione* for once had the benefit of a meditative text with some distinction of style; and in closing the first part with a dominant seventh on the word *"pensaci"* he achieved a stroke of genius which at the present day would still startle the listener and leave his mind in the desired frame of meditative astonishment.

But words fail to characterize the libretto of Beethoven's unfortunate *Christus am Oelberge* (*c.* 1800). The texts of Lutheran church-music had often been grotesque and even disgusting; but their barbarity was pathetic in comparison with the sleek vulgarity of a libretto in which not only is the agony of the garden of Gethsemane represented by an aria (as in Handel's lamentation of Haman), but Christ sings a brilliant duet with the ministering angel. In after years Beethoven had not a good word for this work, which, nevertheless, contains some beautiful music exquisitely scored. And justice demands praise for the idea of making a Hallelujah chorus conclude the work as soon as the betrayal of Christ has been accomplished, thus compensating for the irreverent opening by avoiding all temptation to treat the rest of the passion-story with the same crassness. A well-meant effort was made to provide the *Mount of Olives* with an inoffensive subject in English, but the stupidity of *Engedi: or David in the Wilderness* passes belief.

Schubert's interesting fragment *Lazarus* is strangely prophetic of Wagnerian continuity and has a morbid beauty that transcends its sickly text. There are signs that the despair of the Sadducee was going to be treated with some power. The result might have been a masterpiece; but fate ruled that the next advance should again be Protestant.

Bach's Passions were rediscovered by the boy Mendelssohn after a century of ignorance of their very existence; and in *St. Paul* (*Paulus*) and *Elijah* (*Elias*) rose upon the early middle 19th century like the sunrise of a new Handel.

To-day *St. Paul* has almost sunk below the horizon; and *Elijah,* which still shares with *The Messiah* the Christmas repertoire of every British urban choral society, is in many points an easy target for criticism. Yet the ascendancy of Mendelssohn is the one redeeming feature in the history of oratorio during the first three quarters of the 19th century. Let us admit the defects of *Elijah;* the all too lifelike tiresomeness of the widow (achieved after strenuous revision), the parochial softness of the double quartet, the Jewishness of the Jews (but is this a defect?), and the snorts of the trombones whose third summons causes the Almighty to capitulate: when all these unconscious profanities are discounted, there remains a vivid and coherent oratorio that, musically and

dramatically, towers above later works by many accomplished composers who despise it. (*See* MENDELSSOHN-BARTHOLDY, JAKOB LUDWIG FELIX.) Spohr is the only contemporary of Mendelssohn whose sacred music is still known. So tremendous a subject as that of *The Last Judgment* ought, indeed, to be treated with reserve; but the softness and slowness which pervades nine-tenths of Spohr's work is not reserve but self-indulgence. Spohr has moments of vision; but an almost random glance at the pages of *St. Paul* shows that even in eclipse Mendelssohn has characterization, movement and the capacity for dramatic moments.

In England, the influence of Mendelssohn completed the devastation begun by our inveterate habit of praising the inspired literary skill of the sacred narrative, as a preface to our restatement of it in 40 times as many words of our own. Deans and chapters listened in graceful official pride and imperfectly secret glee to the strains in which the cathedral organist celebrated with equal realism the destruction of Sennacherib's hosts and his own octuply-contrapuntal doctorate of music. Before 1880 our composers had, as Dr. Walker says, "set with almost complete indiscrimination well-nigh every word of the Bible." Had they confined themselves to the second chapter of Ezra they would have escaped dangers of unconscious humour that lurk in the opportunities for "naturalness" in declaiming the dialogues and illustrating the wonders of scriptural narrative.

Neither Sterndale Bennet nor Macfarren improved matters; but Parry and Stanford, towards the end of the century, completely changed the situation. Stanford's *Eden* has a libretto by Robert Bridges. The disgruntled professional librettists, who were also musical critics, had the effrontery to say that this magnificent poem would be the better for extensive cuts. The real truth is that Stanford's music, especially in its orchestral introductions, is diffuse. But it has many beautiful features, and achieves a coherent scheme on exactly such lines of Wagnerian continuity as can be applied to oratorio. Parry preferred to be his own librettist, and by this means he achieved more significant results. The lapses of the amateur poet are less distressing than the *clichés* of the ordinary professional librettist; and the works of Parry and Stanford permanently raised English oratorio from squalor and made it once more an art-form which educated people could enjoy. Some of Parry's architectonic and dramatic ideas will never lose the power to thrill, if only the works as wholes can live in spite of a certain dryness of melody and heaviness of texture. For example, the exploit of Judith is shown with a total avoidance of the cheap and salacious opportunity for a scene between her and Holofernes. Instead, we listen to the watchmen anxiously making their circuit of the city walls in darkness. The music of their march is at a low pitch. It is reaching a normal close when, high above the tonic chord, the cry of Judith bids the watchmen open the gates to her. If this moment cannot thrill, there is no meaning in art. In *King Saul* Parry made a significant discovery as to the emancipation of dramatic oratorio from the stage conditions of time and space. The Witch of Endor prophesies the battle of Gilboa. Her tale becomes real in the telling and is immediately followed by the final dirge.

As with opera, so, but more easily, with oratorio, the method of Wagnerian continuity at last enabled composers to take extant poems and set them to music in their entirety. Thus the fragrant mysticism of Roman Catholic oratorio, dimly adumbrated in Schubert's *Lazarus,* at last came to fruition in Elgar's wonderful setting of Newman's *Dream of Gerontius,* while the old miracle play *Everyman* was very successfully composed by Walford Davies. In his later works, *The Apostles* and *The Kingdom,* Elgar pursues a comprehensive religious design on texts arranged by himself. Oratorio on the basis of Wagnerian continuity and *Leit-motif* is unquestionably a living art-form. Its greatest difficulty is its fatal facility. The oratorio-composer is lost who omits to transcend the limits of the stage; yet when these are transcended only the stedfastness of genius can prevent the composer from sinking to the fashion-storming eclecticism of Honegger's *Le Roi David* which, with the aid of a reciter to read the Bible, takes up the arts of all periods from Handel on and drops each of them before anything like an art-problem arises.

Why not follow more often the method of *The Messiah* and of *Israel in Egypt;* and deal with religious subjects in terms of prophecy and psalm? Brahms's *Deutsches Requiem* is really an oratorio; and since its production (all but one later movement) in 1866 it continues year by year to tower over all other choral music since Beethoven's Mass in D. Form, disciplined form, is not the only thing needed to save future oratorios from the limbo of vanity; but it is their first need. (D. F. T.)

ORATORY, the art of speaking eloquently or in accordance with the rules of rhetoric (*q.v.*).

ORATORY OF ST. PHILIP NERI, CONGREGATION OF THE, or ORATORIANS, a religious order consisting of a number of independent houses, first organized in 1575 by the Florentine priest, Philip Neri (*see* NERI, PHILIP.)

ORBIGNY, ALCIDE DESSALINES D' (1802–1857), French palaeontologist, was born at Couërzon, Loire Inférieure, on Sept. 6, 1802, and was educated at La Rochelle. His first appointment was as travelling naturalist for the Museum of Natural History at Paris. He went in 1826 to South America, and gathered much information on the natural history and ethnology, embodying the results in his great work *Voyage dans l'Amérique Méridionale* (1839–1842). Then, in 1840 he began to publish his *Paléontologie Française, ou description des fossiles de la France,* a monumental work, accompanied by figures of the species. Eight volumes were published by him dealing with Jurassic and Cretaceous invertebrata, and since his death many later volumes have been issued. In 1853 he was appointed professor of palaeontology at the Museum of Natural History in Paris, but died on June 30, 1857, at Pierresitte, near St. Denis.

His works include *Cours élémentaire de paléontologie et de géologie stratigraphiques* (3 vols., 1849–52), and *Prodrome de paléontologie stratigraphique* (3 vols., 1850–52).

ORBIT, in astronomy, is the path of a heavenly body revolving around an attracting centre (from Lat. *orbita,* a track, *orbis,* a wheel); in particular, it denotes the path of a planet or comet around the sun, or of a satellite around its controlling planet.

Kepler's Laws.—In 1609 Johann Kepler announced two laws of planetary motion, and by 1619 he added a third. Kepler's first law is as follows:—A planet moves around the sun in an elliptic orbit, the sun being situated in one focus of the ellipse. If the straight line joining any two points S and T is produced equal distances beyond S and T to A and B, and if P is any point such that the sum of the distances P S and P T is equal to the distance A B, then the aggregate of all such points as P is the curve known as the ellipse. The points S and T are the foci. The curve passes through A and B and A B is called the major axis of the ellipse. If C is the mid-point of A B, the ratio

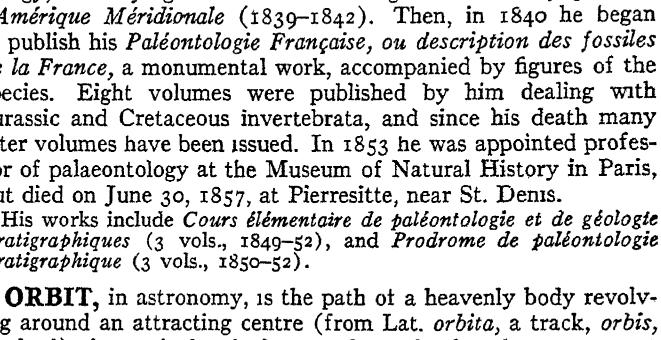

FIG. 1.—DIAGRAM ILLUSTRATING KEPLER'S LAWS OF PLANETARY MOTION

of the length of C S to the length of C A is called the eccentricity. The ellipse then is specified by means of (i) the semi-major axis and (ii) the eccentricity. If the eccentricity happens to be zero, the two foci must coincide at the centre C and the resulting curve is simply a circle; if the eccentricity is precisely unity, then the curve is known as a parabola. Kepler's first law simply states that if the sun is supposed situated at the focus S, the planet's path around the sun—in other words, its orbit—is an ellipse such as is represented in the diagram above. The time required for a complete revolution in the ellipse is the planet's

revolution period; for example, the earth's period of revolution is a little over 365 days; Mercury describes its orbit in 88 days, and Neptune requires 165 years. At A—the point of the ellipse nearest S—the planet is said to be in *perihelion*, and when it reaches B, the most remote point of the ellipse from S, it is said to be in *aphelion*.

Kepler's second law states that the straight line joining the sun to the planet (the radius vector) sweeps out equal areas in equal times. In the preceding figure let D be the position of the planet in its elliptic orbit a month after it reached perihelion (A); similarly let E F be two positions of the planet separated by an interval of a month; the pair of points X, Y are defined in the same way. The shaded area S D A, for example, is the area swept out by the radius vector in one month and by the second law the three shaded areas are equal. Now it is clear from the figure that the arc A D is greater than the arc X Y, for the areas S D A and S X Y are equal and S A and S D are less than S X and S Y; consequently, the velocity of the planet in its orbit must be greater between A and D than between X and Y. More definitely, the velocity of the planet is greatest at perihelion, decreasing gradually until aphelion is reached and thereafter increasing to a maximum again at perihelion.

The figure also shows that the angles described in equal intervals of time by the radius vector vary throughout the orbit; for example the angle D S A is clearly greater than the angle X S Y. The angular velocity is greatest at perihelion and least at aphelion. In one complete revolution around the sun, the radius vector sweeps out 360° and as the period of revolution is accurately known, the average angular velocity is easily deduced. This is known as the "mean motion" and is expressed as so many degrees (or seconds of arc) per day.

Kepler's third law is a relation connecting the semi-major axes of the several planets with their periods of revolution. In Kepler's time, the mean distance of any one planet from the sun was not known in miles but it was known fairly accurately in terms of the earth's mean distance from the sun regarded as the unit of the distance; in other words, the planetary system had been fairly correctly mapped out but the scale of the map was lacking. Also, the periods of the several planets were known with considerable accuracy. The third law expressed in words is: the cube of the semi-major axis of any planetary orbit divided by the square of the period of revolution is the same whatever planet is considered. If the year is regarded as the unit of time and the earth's mean distance from the sun as the unit of distance (this is known as the astronomical unit of distance) the quotient above for the earth is plainly unity and consequently by the third law the cube of the semi-major axis of any other planet (expressed in terms of the astronomical unit) must be equal to the square of the planet's period (expressed in years).

The Orbit in Space.—We have seen that the elliptic orbit of a planet is specified by the eccentricity and the semi-major axis. To apply Kepler's first and second laws to predict the positions of the planet in its orbit at any time it is necessary to know in addition the time when it occupied any definite position in the orbit or the time when it passed through perihelion. The eccentricity, the length of the semi-major axis and the time of perihelion passage constitute three elements of the planet's orbit.

The planetary motions do not all take place in the same plane and consequently the plane of the orbit of a particular planet must be specified with reference to some fundamental plane: the plane chosen is that of the earth's orbit and is called the plane of the ecliptic. Imagine a sphere drawn with the sun at the centre. The plane of the earth's orbit will cut the sphere in a circle (the ecliptic) and the orbital plane of any other planet will cut the sphere in another circle inclined at some definite angle to the plane of the ecliptic. The two circles intersect at two points N and M—called the Nodes. Let V denote a definite reference point on the ecliptic—the direction S V may be thought of as the direction of a particular star as seen from the sun. The point V is known as the "vernal equinox" or "First point of Aries"; it is not necessary here to specify it more particularly. The plane of the planet's orbit is completely specified—with reference to the ecliptic and the point V—by (i) the inclination of the planet's plane to the plane of the ecliptic and (ii) the position of the node N with respect to the point V. The latter is evidently given by the angle subtended at the sun by the radii S V and S N, and this angle is known as the longitude of the node. One thing more requires to be done and that is to specify the orientation of the orbital ellipse in its plane; this is accomplished by specifying the direction of perihelion—in the figure this is indicated by the direction S A. The sum of the angles subtended at S by the arcs V N and N A is called the longitude of perihelion. It should be noticed that there is an ambiguity as to the meaning of the expression "longitude of the node" for there are two nodes N and M. If the upper hemisphere in the figure contains the north pole of the heavens, the radius vector of the earth's orbit moves in the direction S V towards S N as indicated by the arrow; and if the radius vector of the planet moves in the direction S N towards S A, as indicated by the arrow, then N is called the ascending node and M the descending node and (ii) above more precisely should be "the longitude of the ascending node." The ambiguity consequently disappears.

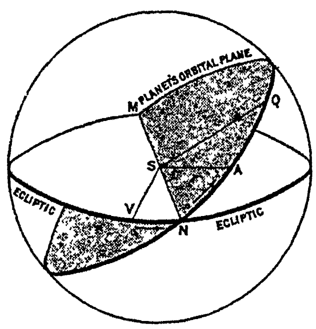

FIG. 2.—PLANET'S ORBITAL PLANE IN RELATION TO THE ECLIPTIC

To summarize; a planet's orbit in space is completely specified by the six elements: (i) the semi-major axis, (ii) the eccentricity, (iii) the time of perihelion passage, (iv) the longitude of the ascending node, (v) the longitude of perihelion, (vi) the inclination of the orbital plane to the plane of the ecliptic.

When the six elements of a planet's orbit are known the position of the planet (the effects of the attractions of the other planets not being taken into account) with reference to the sun and the fundamental plane (the ecliptic) can be calculated for any future date by principles essentially contained in Kepler's laws. The earth's orbit also being known, the position of the planet in the heavens, as seen from the earth, can then be deduced.

The Orbit from Observations.—The reverse problem is to determine the elements of the orbit from actual observations of position made from the earth. When a minor planet or comet is discovered it is important to determine the six elements of its orbit, thus enabling the astronomer to follow subsequently its wanderings even without the aid of observational appliances. A single complete observation of a planet consists in determining its right ascension and declination; three such complete observations at intervals, say, of a month are sufficient to allow the calculation of the six orbital elements.

Boston, U.S.A. 1926), for the non-specialist reader. (W. M. S.)

ORCAGNA (*c.* 1308–*c.* 1368), Italian painter, sculptor, worker in mosaic and architect, whose full name was ANDREA DI CIONE, called ARCAGNUOLO, was the son of a Florentine goldsmith, Maestro Cione, said to have been one of the principal artists who worked on the magnificent silver frontal of the high altar of San Giovanni, the Florentine Baptistery. The result of Orcagna's early training in the use of the precious metals may be traced in the extreme delicacy and refined detail of his principal works in sculpture. His brothers, Lionardo or Nardo, the eldest, a painter; Matteo, a sculptor and mosaicist, and Jacopo, also a painter, were often associated with Orcagna in his varied labours.

From the time of Giotto to the end of the 14th century Orcagna stands pre-eminent among the many excellent artists of that time.

1. *Orcagna as a Painter.*—He was admitted to the guild of the Medici and Speziali, where his name first occurs in the documents of 1344. His chief works in fresco were at Florence, in the church of Sta. Maria Novella. He covered the walls of the retro-choir

with scenes from the life of the Virgin. These, unfortunately, were much injured by damp very soon after their completion, and towards the end of the following century were replaced by other frescoes of the same subjects by Ghirlandaio, who, according to Vasari, made much use of Orcagna's motives and invention. Vasari says that Orcagna also painted the Strozzi chapel in the same church in company with his brother. But Ghiberti attributes these works to his brother Nardo alone. These frescoes still exist though much restored; modern criticism is inclined to attribute them to Nardo. The finest composition is that on the west wall, unbroken by any window. It represents paradise, with Christ and the Virgin enthroned in majesty among rows of brilliantly coloured cherubim and seraphim tinged with rainbow-like rays of light. Here Andrea Orcagna may have had a share in the execution.

In 1357 Orcagna painted one of his finest panel pictures, as a retable for the altar of the same chapel, where it still remains. In the centre is Christ in majesty between kneeling figures of St. Peter and St. Thomas Aquinas, attended by angel musicians; on each side are standing figures of three other saints. It is painted with extreme miniature-like delicacy, and is on the whole very well preserved. This retable is signed, "An. dni. mccclvii. Andreas Cionis de Florentia me pinxit." It is the only certified painting by Orcagna in existence. According to Vasari, he also painted some very fine frescoes in Sta. Croce. Of these only a small fragment remains. Orcagna's figures are plastically conceived, and clearly defined by a firmly drawn contour. They stand out against the background like statues.

2. *Orcagna as a Sculptor and Architect.*—Orcagna was admitted as a member of the Sculptors' Gild in 1352. His name occurs in the roll as "Andreas Cionis vocatus Arcagnolus, pictor." According to Vasari, Orcagna worked under Andrea Pisano as a pupil in sculpture. His style, however, constitutes an advance on Andrea's art and prepares the way for the coming Renaissance. In 1359 he completed the great marble tabernacle for the chapel of Or San Michele. This, in its combined splendour of architectural design, sculptured reliefs and statuettes, and mosaic enrichments, is one of the most important and beautiful works of art which even rich Italy possesses.

ORCHARDSON, SIR WILLIAM QUILLER (1832–1910), British painter, was born in Edinburgh on March 27, 1832. At 13½ he went to the Trustees' academy. At 20, Orchardson had mastered the essentials of his art, and for seven years after this he worked in Edinburgh, devoting himself partially to "black and white." In 1862 he came to London, and established himself in 37, Fitzroy square, where his friend John Pettie joined him.

The English public was not immediately attracted by Orchardson's work, which was too quiet to compel attention at the Royal Academy, and Pettie, Orchardson's junior by seven years, at first outshone him. Orchardson confined himself to the simplest themes and designs and the most reticent schemes of colour. In 1865 Pettie married, and the Fitzroy square *ménage* was broken up. Orchardson married Miss Helen Moxon in 1873. In 1868 he was elected A.R.A. and in 1877 R.A. He died on April 13, 1910.

Orchardson's first great success was gained in 1881, when he exhibited "On Board the 'Bellerophon'" (now at the Tate gallery) at the Royal Academy, and for the next ten or twelve years his exhibits enjoyed unfailing popularity. "The Voltaire" (1883) (now in the Kunsthalle, Hamburg) is perhaps his finest composition. The "Mariage de convenance" (1884) and "A Tender Chord" (1886) were two of his most famous paintings, and about this time he exhibited a series of period pictures.

Among his portraits are "Master Baby," "The Provost of Aberdeen" and "Sir Walter Gilbey, Bart." Other paintings are "After" (sequel to "Mariage de convenance"), and "The Young Duke."

ORCHESTRA. In ancient Greece the ὀρχήστρα was the space between the auditorium and the proscenium or stage, in which were stationed the chorus and the instrumentalists. In its modern acceptation the word means either that portion of a theatre or concert-hall provided for the accommodation of the instrumentalists or the body of instrumentalists itself; by extension in the U.S.A. it means the main floor of the theatre.

The modern orchestra is composed of (1) a basis of strings—first and second violins, violas, violoncellos and double basses; (2) flutes, sometimes including a piccolo; (3) the reed contingent, consisting of two complete families, (*a*) the oboes with their tenors and basses (the cor anglais, the fagotto or bassoon and the contrafagotto or double bassoon), (*b*) the clarinets with their tenor and basses (the basset horn and the bass and pedal clarinets), with the addition sometimes of saxophones; (4) the brass wind, consisting of the horns, a group sometimes completed by the tenor and tenor-bass Wagner tubas, the trumpet or cornet, the trombones (tenor, bass and contrabass), the tubas (tenor, bass and contrabass); (5) a harp or harps; (6) the percussion instruments, including the kettledrums, bells, Glockenspiel, cymbals, triangle, etc.; to which are sometimes added a celesta and a pianoforte, to say nothing of such "extras" as the rattle employed by Richard Strauss in *Till Eulenspiegel,* the wind machine required by the same composer in *Don Quixote,* the iron chains introduced by Schönberg in his *Gurrelieder,* and so on.

Although most of the instruments from the older civilizations of Egypt, Chaldea, Persia, Phoenicia and of the Semitic races were known to the ancient Greeks, they did not share in any way their neighbours' love of orchestral effects, obtained by combining harps, lyres, guitars, tanburs, flutes, trumpets, bagpipes, cymbals, drums, etc., playing in unison or in octaves. The Greeks only cultivated to any extent the various kinds of citharas, lyres and auloi, and these were seldom used in concert. To the predilection of the Romans for wind instruments of all kinds we owe nearly all the wind instruments of the modern orchestra, each of which had its prototype among the instruments of the Roman empire: the flute, oboe and clarinet, in the tibia; the trombone and trumpet in the buccina; the tubas in the tuba; and the French horn in the cornu and buccina.

The 4th century A.D. witnessed the downfall of the Roman drama and the debasement of instrumental music, which was placed under a ban by the Church. During the convulsions which the migrations of Goths, Vandals and Huns caused in Europe after the fall of Rome instrumental music was preserved from absolute extinction by wandering actors and musicians.

The earliest instrumental compositions extant are certain 15th century dances and pieces in contrapuntal style preserved in the libraries of Berlin and Munich. The late development of notation, which long remained exclusively in the hands of monks and troubadours, personally more concerned with vocal than with instrumental music, ensured the preservation of the former, while the latter was left unrecorded. But indications are not wanting of an independent energy and vitality which must surely have existed in unrecorded mediaeval instrumental music, since there is such evidence of this in the instruments themselves. It is, for example, significant of the attitude of the 10th century instrumentalists towards musical progress that they at once assimilated Hucbald's innovation of the *organum,* a parallel succession of fourths and fifths, accompanied sometimes by the octave, for two or three voices respectively, and that they produced in the same century the *organistrum,* named after Hucbald's *organum.*

At the time of the revival of the drama with music, afterwards modified and known as opera, at the end of the 16th century, there was as yet no orchestra in our sense of the word, but merely an abundance of instruments used in concert for special effects, without balance or grouping; small positive organs, regals, harpsichords, lutes, theorbos, archlutes, chittarone (bass and contrabass lutes), guitars, viols, lyras *da braccio* and *da gamba,* psalteries, citterns, harps, flutes, recorders, cornets, trumpets and trombones, drums and cymbals.

Monteverde was the first to see that a preponderance of strings is necessary to ensure a proper balance of tone. With the perfected models of the Cremona violins at his disposal, a quartet of strings was established and all other stringed instruments not played with the bow were ejected from the orchestra, with the exception of the harp. Under the influence of Monteverde and his

successors, Cavalli and Cesti, the orchestra won for itself a separate existence with music and laws of its own. As instruments were improved, new ones introduced, and old ones abandoned instrumentation became a new and favourite study in Italy and in Germany, and musicians began to find out the capabilities of the various families of instruments and their individual value.

At first the orchestra was an aristocratic luxury, performing privately at the courts of the princes and nobles of Italy; but in the 17th century performances were given in theatres, and Germany eagerly followed. Dresden, Munich and Hamburg successively built opera houses, while in England opera began with the masque, and in France Lully, with the collaboration of Molière, also greatly raised the status of the entertainments known as *ballets,* interspersed with instrumental and vocal music.

The revival of the drama seems to have exhausted the enthusiasm of Italy for instrumental music and the field of action was shifted to Germany, where the perfecting of the orchestra was continued. Most German princes had at the beginning of the 18th century good private orchestras or *Kapelle,* and they always endeavoured to secure the services of the best available instrumentalists. Kaiser, Telemann, Graun, Mattheson and Handel contributed greatly to the development of German opera and of the orchestra in Hamburg during the first quarter of the century. Gluck, the reformer of opera, and Mozart; Haydn, the father of the modern orchestra and the first to treat it independently as a power opposed to the solo and chorus, by scoring for the instruments in well-defined groups; Beethoven, who individualized the instruments, writing solo passages for them; Weber, who brought the horn and clarinet into prominence; Schubert, who inaugurated the conversations between members of the wood wind—all left their mark on the orchestra, leading the way up to Wagner, Strauss and their successors.

ORCHESTRATION: *see* INSTRUMENTATION.

ORCHESTRION, a name applied to three different kinds of musical instruments: (1) a chamber organ, designed by Abt Vogler at the end of the 18th century; (2) a pianoforte with organ pipes attached, invented by T. A. Kunz of Prague in 1791; (3) a mechanical wind orchestra, automatically played by means of revolving cylinders, invented in 1851 by F. T. Kaufmann of Dresden.

ORCHHA (also called *Tehri* or *Tikamgarh*), an Indian state in the Bundelkhand agency of Central India. It is the oldest and highest in rank of all the Bundela principalities, and was the only one not held in subjection by the peshwa. Area, 1,999 sq.mi., pop. (1941) 363,405. The maharaja, Shri Vir Singh Deo, K.C.S.I. (born in 1899, succeeded in 1930), bears the hereditary title of "First of the Princes of Bundelkhand." The state exports grain, *ghi,* and cotton cloth, but trade suffers from imperfect communications.

The town of Orchha, the former capital, is on the river Betwa, not far from Jhansi. It possesses an imposing fort, dating mainly from the early 17th century, with two magnificent palaces—the Rajmandir, a massive square erection of which the exterior is almost absolutely plain, and the Jahangirmahal, a singularly beautiful specimen of Hindu domestic architecture. Elsewhere about the town are fine temples and tombs, among which may be noticed the Chaturbhuj temple on its vast platform of stone. The town of Tehri or Tikamgarh, where the chief now resides, is about 40 mi. S. of Orchha; population 14.096. The maharaja has a salute of 15 guns.

ORCHIDS, the name given to members of the orchid family (Orchidaceae), one of the most numerous and interesting groups of flowering plants, usually with beautiful and often with exceedingly handsome and highly fragrant flowers. Orchids are found in most climates throughout the world, except in the polar regions, but they occur in by far their greatest diversity and abundance in humid tropical forests. The orchids are all perennial herbs or vines, as in *Vanilla,* and are comprised in two groups: (1) terrestrial orchids, which grow in the ground, and (2) epiphytic orchids, epiphytes, which grow perched upon trees, found in the tropics, where they form an important feature of the vegetation. Most orchids of the temperate zone are terrestrial.

Floral Structure.—The flowers of orchids, though extremely diverse within certain limits, are all formed upon one common plan, which is only a modification of that observable in such flowers as those of the narcissus. Such flowers consist essentially in the presence of a six-parted perianth, the three outer segments of which correspond to a calyx, the three inner ones to a corolla. These segments spring from the top of the ovary which is inferior instead of superior as in the lily. Within the perianth, and springing from its sides, or apparently from the top of the ovary, are six much modified or suppressed stamens. These stamens encircle a style which is the upward continuation of the ovary and which shows at its free end traces of the three originally separate but now blended carpels of which the ovary consists.

An orchid flower has an inferior ovary, but with the ovules on the walls of the cavity (not in its axis or centre), a six-parted perianth, a stamen or stamens and stigmas. The main distinguishing features consist in the fact that one of the inner pieces of the perianth becomes in course of its growth much larger than the rest, and usually different in colour, texture and form. So different is it that it receives a distinct name, that of the "lip" or "labellum." In place of the six stamens we commonly find but one (two in *Cypripedium*), and that one is raised together with the stigmatic surfaces on an elongation of the floral axis known as the "column." Moreover, the pollen, instead of consisting of separate cells or grains, consists of cells aggregated into usually sticky "pollen masses," the number varying in different genera, but very generally two, four or eight. In *Cypripedium* all three stigmas are functional, but in most orchids only the lateral pair form receptive surfaces, the third being sterile and forming the rostellum, which plays an important part in the process of pollination, often forming a peculiar pouch-like process in which the viscid disk of the pollen masses is concealed.

It would appear, then, that the orchid flower differs from the more general monocotyledonous type in the irregularity of the perianth, in the suppression of five out of six stamens, and in the union of the one stamen and the stigmas. In addition to these modifications, which are common to nearly all orchids, there are others generally but not so universally met with; among them is the displacement of the flower arising from the twisting of the inferior ovary, in consequence of which the flower is so completely turned round that the "lip," which originates in that part of the flower conventionally called posterior, or that nearest to the supporting stem, becomes in course of growth turned to the anterior part of the flower nearest to the bract. Other common modifications arise from the union of certain parts of the perianth to each other, and from the varied and often very remarkable outgrowths from the lip. These modifications are associated with the structure and habits of insects and their visits to the flowers.

Cross-Pollination by Insects.—In the common orchids of British meadows, *Orchis maculata, O. mascula* (Shakespeare's long purples), etc., the general structure of the flower is as described. In addition there is in this particular genus, as indeed in many others, a long tubular spur or horn projecting downwards from the back of the lip, whose office it is to secrete and store a honeyed juice; the forepart of the lip forms an expanded plate, usually larger and more brightly coloured than the other parts of the flower, and with hairs or ridges and spots of various kinds according to the species. The remaining parts of the perianth are much smaller, and commonly are so arranged as to form a hood overarching the "column." This column stands up from the base of the flower, almost at right angles to the lip, and it bears at the top an anther, in the two hollow lobes of which are concealed the two pollen-masses, each with its caudicle terminating below in a roundish gland, concealed at first in the pouch-like rostellum at the front of the column. Below the anther the surface of the column in front is hollowed out into a greenish depression covered with viscid fluid—this is the two united stigmas.

In the process of pollination a bee alights on the lip. There, guided by the hairs or ridges, it is led to the orifice of the spur with its store of honeyed juice. The position of this orifice, as we have seen, is at the base of the lip and of the column, so that the in-

PAINTED FOR THE ENCYCLOPÆDIA BRITANNICA BY ISABEL COOPER AFTER SPECIMENS GROWN BY JOSEPH MANDA

EIGHT VARIETIES OF CULTIVATED ORCHIDS

The orchid family, one of the most interesting groups of flowering plants, comprises upwards of 7,000 species, found most abundantly in the Tropics. Several hundred species are grown in greenhouses; from these, gardeners have developed many varieties and an immense number of hybrid forms

1. Thwaites' Dendrobium (*Dendrobium Thwaitesiae*). 2 Venus Dendrobium (*D. Falconeri* x *nobile*). 3. Moth orchid (*Phalaenopsis Lueddemanniana*) 4. Alexander's Cymbidium (*Cymbidium Alexanderi*). 5. Argus lady slipper (*Cypripedium Argus*). 6. Sander's lady slipper (*Cypripedium insigne Sanderae*). 7. Queen Cattleya (*Cattleya Dowiana aurea*). 8. Triana Cattleya (*Cattleya Trianae*)

sect, if of sufficient size, while bending its head to insert the proboscis into the spur, almost of necessity displaces the pollen-masses. Liberated from the anthers, these adhere to the head or back of the insect by means of the sticky gland at the bottom of the caudicle. Having sipped the nectar the insect withdraws, taking the pollen-masses with it, and visits another flower. The two anther-cases in an orchis are erect and nearly parallel to each other; the pollen-masses within them are of course in the like position. Immediately, however, the pollen-masses are removed, movements take place at the base of the caudicle so as to effect the bending of this stalk, bringing the pollen-mass in a more or less horizontal position, or, as in the case of *O. pyramidalis,* the two pollen-masses originally placed parallel diverge from the base like the letter V. The movements of the pollen-masses may readily be seen with the naked eye by thrusting the point of a needle into the base of the anther, when the disks adhere to the needle as they would to the antenna of an insect, and may be withdrawn. Sometimes the lip is mobile and even sensitive to touch, as are also certain processes of the column. In such cases the contact of an insect or other body with those processes is sufficient to liberate the pollen often with elastic force, even when the anther itself is not touched.

In other orchids movements take place in different ways and in other directions. The object of these movements will be appreciated when it is remembered that if the pollen-masses retained the original direction they had in the anther in which they were formed, they would, when transported by the insect to another flower, merely come in contact with the anther of that flower, where of course they would be of no use; but owing to the divergences and flexions above alluded to, the pollen-masses come to be so placed that, when transplanted to another flower of the same species, they come in contact with the stigma and so effect the pollination of that flower. The adaptions of orchid flowers to fertilization by insects are very numerous and often remarkably complicated. Darwin devoted two volumes to the subject.

Propagation and Growth.—The fruit of orchids is a capsule which usually splits by three lengthwise slits, forming valves that remain united above and below. The seeds, minute and innumerable, are well-adapted to wind dissemination. In many species the seeds lose their viability after a few months and often are slow and difficult to germinate after planting, some requiring from three months to two years. The roots of terrestrial orchids are often bulbous and still more frequently more or less tuberous, the tubers being partly radical and partly budlike, so that propagation of new individuals by division from the parent takes place. Often there is a marked alternation in the production of vegetative and flowering shoots; sometimes the flowering shoots are not produced for several years in succession. This accounts for the profusion with which various orchids are found in flower in some seasons and for their scarcity in others.

Tropical orchids are mostly epiphytal—that is, they grow upon trees without deriving nourishment from them. They are frequently provided with pseudobulbs, large solid swellings of the stem in the tissues of which water and nutritive materials are stored. They derive this moisture from the air by means of aerial roots developed from the stem and bearing an outer spongy structure, or *velamen,* consisting of empty cells kept open by spiral thickenings in the wall; this sponge-like tissue absorbs dew and rain and passes it on to the internal tissues.

Classification.—In number of species the orchid family is exceeded by only two or three other families of flowering plants. Conservatively stated, it contains at least 7,500 species comprised in 450 genera; some authorities place the number of species as high as 15,000.

The family is divided into two main groups based on the number of the stamens and stigmas. The first, Pleonandrae, has two or rarely three fertile stamens and three functional stigmas. It contains two small genera of tropical Asia and Africa with almost regular flowers, and the large genus *Cypripedium,* containing about 350 species in the north temperate zone and tropical Asia and America. In *Cypripedium* two stamens are present, one on each side of the column, instead of one only at the top, as in the group Monandrae, to which belong the remaining genera in which also only two stigmas are fertile.

The Monandrae have been subdivided into 20 tribes, the characters of which are based on the structure of the anther and pollinia, the nature of the inflorescence, whether terminal or lateral, the vernation of the leaf and the presence or absence of a joint between blade and sheath, and the nature of the stem. The most important are the following:

Ophrydeae, terrestrial orchids, mainly north temperate, including the genera *Orchis, Aceras, Ophrys, Herminium, Gymnadenia* and *Habenaria.*

Neottieae, also terrestrial, contains 13 more or less widely distributed tropical or subtropical subtribes; one, *Cephalanthereae,* which includes the genera *Cephalanthera* and *Epipactis,* is chiefly north temperate. The genera *Spiranthes, Listera* and *Neottia* are also included in this tribe, as is also *Vanilla,* the elongated stem of which climbs by means of tendril-like aerial roots.

Coelogyneae, mostly epiphytes, and inhabitants of tropical Asia. A single internode of each shoot is swollen to form a pseudobulb.

Liparideae, terrestrial, two, *Malaxis* and *Corallorhiza,* are Eurasian and North American. *Liparis* is a large genus widely distributed in the tropics.

Pleurothallidieae, natives of tropical America, one of which, *Pleurothallis,* contains about 500 species. *Masdevallia* is common in cultivation and has often brilliant scarlet, crimson or orange flowers.

Laelieae, natives of the warmer parts of America, including three of those best known in cultivation, *Epidendrum, Cattleya* and *Laelia.*

Phajeae, chiefly tropical Asiatic, some—*Phajus* and *Calanthe*—spreading northward into China and Japan.

Cyrtopodieae, tropical, but extending into north temperate Asia and South Africa; *Eulophia* and *Lissochilus* are important African genera.

Cataseteae, with tropical American genera, two of which, *Cataselum* and *Cycnoches,* have di- or tri-morphic flowers.

Dendrobieae, in the warmer parts of the old world; the chief genus is *Dendrobium,* with 750 species, often with showy flowers.

Cymbidieae, in the tropics of the old world. The leaves are generally long and narrow. *Cymbidium* is well known in cultivation.

Oncidieae, in the warmer parts of America. *Odontoglossum* and *Oncidium* include some of the best-known cultivated orchids.

Sarcantheae, in the tropics. *Vanda* (Asia) and *Angraecum* (Africa and Madagascar) are known in cultivation. The flower of *Angraecum sesquipedale* has a spur about 1 ft. in length.

British Orchids.—The family is well represented in Great Britain by nearly 40 species representative of 18 genera; among these are several species of *Orchis, Gymnadenia* (fragrant orchis), *Habenaria* (butterfly and frog orchis), *Aceras* (man orchis), *Herminium* (musk orchis), *Ophrys* (bee, spider and fly orchis), *Epipactis* (helleborine), *Cephalanthera, Neottia* (bird's-nest orchis), one of the few saprophytic genera, which have no green leaves but derive their nourishment from decaying organic matter in the soil, *Listera* (tway blade), *Spiranthes* (lady's tresses), *Malaxis* (bog-orchis), *Liparis* (fen-orchis), *Corallorhiza* (coral root), also a saprophyte, and *Cypripedium* (lady's slipper), represented by a single species, now very rare, in limestone districts in the north of England.

North American Orchids.—In North America north of Mexico about 140 species of orchids are found, representing some 40 genera (*see* O. Ames, *An Enumeration of the Orchids of the United States and Canada,* 1925). Many are widely distributed across the continent, some extending to Alaska and even to Greenland, but they occur most numerously in the eastern and especially the southeastern states. The generic groups having the largest number of species are the rein-orchises (*Habenaria*), 40 species; lady's-tresses (*Spiranthes*), 15 species; lady's-slippers (*Cypripedium*), 14 species; and bog-orchises (*Malaxis*), 8 species. The tropical epiphytes are represented by *Epidendrum,* 9 species, and *Oncidium,* 6 species, found in Florida. Among the many attractive

orchids native to the eastern states and provinces are the showy lady's-slipper (*C. reginae*), the yellow lady's-slipper (*C. parviflorum*), the moccasin-flower (*C. acaule*), the showy orchis (*Orchis spectabilis*), the shin plasters (*O. rotundifolia*), the white-fringed orchis (*H. blephariglottis*), the yellow-fringed orchis (*H. ciliaris*), the small purple-fringed orchis (*H. psycodes*), the rose-pogonia or snake-mouth (*Pogonia ophioglossoides*), the dragon's-mouth (*Arethusa bulbosa*) and the grass-pink (*Calopogon pulchellus*).

In the Rocky mountain region and adjacent plains some 40 species of orchids occur; fully half of these are found also in the eastern states and a dozen or more extend northward to Alaska. Among them are the mountain lady's-slipper (*Cypripedium montanum*), the oval-leaved orchis (*Habenaria Menziesii*). About 35 species of orchids occur in the Pacific states; among these are the California lady's-slipper (*Cypripedium californicum*), the Sierra rein-orchis (*Habenaria leucostachys*), the giant helleborine (*Epipactis gigantea*) and the rare phantom orchis (*Cephalanthera Austinae*).

Cultivation.—The only orchid of substantial economic importance, furnishing a staple article of extensive use, is vanilla (*q.v.*). But the number of tropical orchids grown in greenhouses in Europe and North America for the flower markets, and as objects of horticultural and scientific interest, is immense. More than 3,000 species, many of them epiphytes, are in cultivation, as well as many thousand hybrid forms derived from them. Among the genera thus represented in orchid culture are *Cattleya, Cypripedium, Dendrobium, Epidendrum, Laelia, Odontoglossum* and *Phalaenopsis*. Many bi-generic hybrids have been developed by orchid fanciers. Propagation of these cultivated forms is by division, cuttings and growth from seed. Many terrestrial orchids practically defy all efforts at cultivation, due to lack of knowledge regarding soil conditions, to saprophytic habits, and to their growth in association with special fungi (*see* MYCORRHIZA).

ORCHOMENUS (on coins and inscriptions, *Erchomenos*), the name borne by two cities of ancient Greece.

1. A Boeotian city, between the Cephissus river and its tributary, the Melas, on a long, narrow hill projecting south from Mt. Acontium, on every side admirably situated to be the stronghold of an early kingdom. The acropolis is situated at the north end of the ridge.

In prehistoric times Orchomenus is revealed alike by archaeological finds and by legends, as one of the most prosperous towns of Greece, once a continental and a maritime power. It controlled the greater part of Boeotia, especially the fertile lowlands of Lake Copaïs, upon the drainage of which its early kings bestowed great care. Its original inhabitants, the Minyae, were a seafaring people, and Orchomenus remained a member of the Calaurian League of naval States till historical times. Then, however, Orchomenus no longer figures as a great commercial State, and its political supremacy in Boeotia has passed to the people of Thebes. Nevertheless, it long exercised some overlordship over towns of northern Boeotia, and an independent policy within the Boeotian League. In 447 it was the headquarters of the oligarchic exiles who freed Boeotia from Athenian control. In the 4th century Orchomenus was actuated throughout by an anti-Theban policy, partly a recrudescence of old rivalry, but chiefly inspired by aversion to the new democracy at Thebes. In the Corinthian war the city supported Lysander and Agesilaus in their attacks upon Thebes, and Orchomenus again sided with the Spartans in 379. After the battle of Leuctra the Thebans, first, on Epaminondas's advice, readmitted it into the Boeotian League, but in 368 destroyed the town. By 353 it had been rebuilt, probably by the Phocians, as a bulwark against Thebes. After the subjection of the Phocians in 346 it was again razed by the Thebans, but was restored by Philip of Macedon as a check upon Thebes (338). In 85 B.C. Orchomenus provided the battle-field on which the Roman general Sulla destroyed an army of Mithridates VI. of Pontus. But its later history is obscure, and its decadence is attested by the encroachments of Lake Copaïs. Since mediaeval times the site has been occupied by a village named Skripou. Since 1867 drainage operations have been resumed, and an English company has reclaimed much fertile land. The so-called "treasury of Minyas," outside the ancient city at Mycenae (*see* MYCENAE), is almost exactly the same size as the "treasury of Atreus." The admiration of Pausanias is justified by the beautiful ornamentation of the roof of the inner chamber brought to light by Schliemann. Excavation by Doctors Furtwängler and Bulle revealed three prehistoric settlements, superposed. The first represents the Neolithic "painted-ware" culture of Thessaly and other parts of north-east Greece; in the second, oval huts replace the earlier round ones, and dull smeared pottery ("Urfirniss") the painted ware; the third has rectangular houses and characteristic grey "Minyan" pottery, finely modelled but without ornament. All these cultures precede the "Late Minoan" occupation, to which the great "Treasury" tomb belongs.

The worship of the Charites (*see* GRACES) was the great cult of Orchomenus, and the site of the temple is now occupied by a chapel of the Virgin (Κοίμηδις τῆς Παναγίας). The Charites were worshipped under the form of rude stones, which had fallen from heaven during the reign of Eteocles; and it was not till the time of Pausanias that statues of the goddesses were placed in the temple. Near this was another temple, dedicated to Dionysus, in whose festival, the *Agrionia* (*q.v.*), are apparent the traces of early human sacrifice.

2. An Arcadian city north of Mantineia and west of Stymphalus. Its district was mountainous, but had two valleys—the northern containing a lake drained by a *katavothron;* the southern below the city, separated from Mantineia by the ridge Anchisia. The old city, in a strong situation, was a ruin in Strabo's time. Till the late 7th century the kings of Orchomenus held some sort of sovereignty over all Arcadia. In the 5th century it was overshadowed by Mantineia, and in 418 B.C. Orchomenus fell for a time into its power; in 370 it held aloof from the new Arcadian League which Mantineia was organizing. About this time it also lost some possessions on the east to the new Arcadian capital, Megalopolis. In the 3rd century it belonged in turn to the Aetolian League, to the Lacedaemonians, and, since 222, to the Achaean League. Its history after it passed under the Roman rule is quite obscure.

ORCINOL, a homologne of resorcinol (*q.v.*), found in many lichens, e.g., *Rocella tinctoria, Lecanora,* and formed by fusing extract of aloes with caustic potash. It is 3:5-dihydroxy-1-methylbenzene ($C_6H_3(CH_3)(OH)_2$). It may be synthesized from toluene; or from acetonedicarboxylic ester by condensation with the aid of sodium. It crystallizes in colourless prisms with one molecule of water, which redden on exposure. Ferric chloride gives a bluish-violet coloration with the aqueous solution. Unlike resorcinol it does not give a fluorescein with phthalic anhydride. Oxidation of the ammoniacal solution gives *orcein*, $C_{28}H_{24}N_2O_7$, the chief constituent of the natural dye archil (*q.v.*). Homopyrocatechol is an isomeride ($CH_3:OH:OH=1:3:4$), found as its methyl ether (creosol) in beech-wood tar.

ORDEAL, a term of varying meaning but bearing the special sense of the mediaeval Lat. *Dei iudicium,* a miraculous decision as to the truth of an accusation or claim. The ordeal in principle, and often in the very forms used, belongs to ancient culture. Some ordeals, which possibly represent early stages of the practice, are simply magical, being processes of divination turned to legal purpose. Thus in Burma suits are sometimes still determined by plaintiff and defendant being each furnished with a candle, equal in size and both lighted at once—he whose candle outlasts the other being adjudged to have won his cause (Shway Yoe, *The*

Burman, ii. 254). In Borneo, the two parties are represented by two shell-fish on a plate, which are irritated by pouring on some lime-juice, and the one first moving settles the guilt or innocence (as has been before arranged) of its owner (St. John, *Forests of the Far East*, i. 89). The administration of ordeals has been much in the hands of priests, the intervention of a deity being invoked and assumed to take place even when the process is in its nature one of symbolic magic. The ordeal is related to divination (*q.v.*). *Coscinomancy* (the use of a sieve for divination) served anciently to discover a thief when, with prayer to the gods for direction, the names of the suspected persons were called over it (Potter, *Greek Antiquities*, i. 352). When a suspended hatchet was used in the same way to turn to the guilty, the process was called *axinomancy*. The sieve-ordeal is mentioned in Hudibras (ii. 3):

> . . . th' oracle of sieve and shears
> That turns as certain as the spheres.

In the modern Christian form of the key and bible, a psalter or bible is suspended by a key tied in at Psalm l. 18: "When thou sawest a thief, then thou consentedst with him"; the bow of the key being balanced on the fingers, and the names of those suspected being called over, he or she at whose name the book turns or falls is the culprit (*see* Brand, *Popular Antiquities*).

One form of divination passing into ordeals is the appeal to the corpse itself for discovery of its murderer. Thus the natives of Australia will ask the dead man carried on his bier of boughs, who bewitched him; if he has died by witchcraft he will make the bier move round, and if the sorcerer who killed him be present a bough will touch him (Eyre, *Australia*, ii. 344). Among the negroes of Ashanti, the corpse causes its bearers to dash against the guilty party (R. S. Rattray, *Religion and Art in Ashanti* [1927] p. 167, *see* also B. Malinowski, *Crime and Custom in Savage Society*, H. V. Russell, *Tribes and Castes of the Central Provinces*, [1916] iii. p. 90). The well-known ordeal of the bier in Europe in the middle ages seems founded on a different principle, the imagination that a sympathetic action of the blood causes it to flow at the touch or neighbourhood of the murderer. Apparently the liquefaction of the blood which in certain cases takes place after death may have furnished the ground for this belief. On Teutonic ground, this ordeal appears in the *Nibelungenlied*, where the murdered Siegfried is laid on his bier, and Hagen is called on to prove his innocence by going to the corpse, but at his approach the dead chief's wounds bleed afresh. In Shakespeare (*Rich. III.*, act 1, sc. 2):

> O gentlemen, see, see! dead Henry's wounds
> Open their congeal'd mouths, and bleed afresh!

Certain ordeals are closely related to oaths, so that the two shade into one another. Let the curse which is to fall on the oath-breaker take effect at once, it then becomes a sign condemning the swearer—in fact, an ordeal. Thus the drinking of water on which a curse or magical penalty has been laid is a mere oath so long as the time of fulfilment is unfixed (*see* OATH). But it becomes an ordeal when, as in Brahmanic India, the accused drinks three handfuls of water in which a sacred image has been dipped; if he is innocent nothing happens, but if he is guilty sickness or misfortune will fall on him within one to three weeks (for accounts of these and other Hindu ordeals *see* Ali Ibrahim Khan in *Asiatic Researches*, i. 389, and Stenzler's summary in *Z. D. M. G.*, vol. ix.). Numbers v. describes the mode of administering to a woman charged with unfaithfulness the bitter water mixed with the dust of the tabernacle floor, with the curse laid on it to cause her belly to swell and her thigh to fall if guilty. The term "bitter" is applied to the water before it has been cursed, which suggests that it already contained some drug, as in the poison-water ordeal still in constant use over a great part of Africa. The result of the ordeal depends partly on the patient's constitution, but more on the sorcerer who can prepare the proper dose to prove either guilt or innocence, and thereby acquires boundless influence. The poison-ordeal is also known to Brahmanic law, decoction of aconite root being one of the poisons given, and the accused if not sickening being declared free (Stenzler, *l.c.*). Theoretically connected with the ordeal by cursed drink is that by cursed food. The ordeal by bread and cheese, practised in Alexandria about the 2nd century, was practically the same as that known to English law five to ten centuries later as the *corsnaed* or "trial slice" of consecrated bread and cheese which was administered from the altar, with the curse that if the accused were guilty God would send the angel Gabriel to stop his throat, that he might not be able to swallow that bread and cheese. In fact, if guilty and not a hardened offender he was apt to fail, dry-mouthed and choking through terror, to get it down.

The passing through the fire is described in the Hindu codes of Yâjnavalkya and others, and in the *Râmâyana* the virtuous Sitâ thus proves her innocence to her jealous husband Râma (Stenzler, p. 669; Pictet, *Origines Indo-Européennes*, part ii. p. 457). In European law and chronicle, Richardis, wife of Charles the Fat, proves her innocence by going into a fire clothed in a waxed shift, and is unhurt by the fire (Grimm, *Deutsche Rechtsalterthümer*, p. 912). Yet more minutely prescribed in the Hindu ordeal-books is the rite of carrying the glowing hot iron seven steps, into the seven or nine circles traced on the ground, the examination of the hands to see if they show traces of burning, and the binding them up in leaves. In a Scandinavian law it is prescri[illegible] hot iron shall be carried nine steps (Grimm, *op. cit.*, p. 91[illegible] Anglo-Saxon laws the iron to be carried was at first only one pound weight, but Athelstan's law (in *Ancient Laws and Institutes of England*, iv. 6) increased it to three pounds. Another form well known in old Germany and England was the walking barefoot over glowing ploughshares, generally nine. The law-codes of the early middle ages show this as an ordinary criminal procedure (*see* the two works last referred to). Queen Emma, mother of Edward the Confessor, accused of familiarity with Alwyn bishop of Winchester, triumphantly purged herself and him by the help of St. Swithin—each of the two thus acquitted giving nine manors to the church of Winchester, in memory of the nine ploughshares, and the king being corrected with stripes (John Bromton, *see* Freeman's *Norm. Conq.*, vol. ii. App.). To dip the hand in boiling water or oil or melted lead and take out a stone or ring is another ordeal of this class. Some of these fiery trials are still in use, in regions of Africa or further Asia—the negro plunging his arm into the caldron of boiling oil, the Burman doing feats with melted lead, while the Bedouin will settle a conflict of evidence by the opposing witnesses licking a glowing hot iron spoon (Kennett, *Arabian justice*). This latter feat may be done with safety, provided the iron be clean and thoroughly white hot, while if only red-hot it would touch and burn the tongue. Probably the administerers of the ordeal know this, and the possibility of dipping the hand in melted metal; and there are stories of arts of protecting the skin (*see* the recipe in Albertus Magnus, *De Mirabilibus*), though it is not known what can be really done beyond making it horny like a smith's, which would serve as a defence in stepping on hot coals, but not in serious trials like that of carrying a heavy red-hot iron. The fire-ordeals are still performed by mountebanks. Fire walking is still practised by Hindus and was performed in Natal in the autumn of 1925. The Hindu code of Manu (viii. 115) avers that "He whom the flame does not burn, whom the water does not cast up, or whom no harm soon befalls, is to be taken as truthful in his oath." This water-ordeal is well known in Europe, where the accused is thrown bound into the water, which receives him if innocent, but rejects him if guilty. The directions given by Archbishop Hincmar in the 9th century provide that he who is let down into the water for trial is to be fastened by a rope, that he may not be in danger if the water receives him as innocent, but may be pulled out. In the later middle ages this ordeal by "swimming" or "fleeting" became the most approved means of trying a suspected witch: she was stripped naked and cross bound, the right thumb to the left toe, and the left thumb to the right toe. In this state she was cast into a pond or river, in which it was thought impossible for her to sink (Brand iii. 21). Cases of "ducking" witches which used to occur in England were remains of the ancient ordeal.

When in the warfare of Greeks and Trojans, of Jews and Philistines, of Vandals and Alamans, heroes come out from the two sides and their combat decides the victory, then we have the ordeal by battle. A passage from old German law shows the single

combat accepted as a regular legal procedure: "If there be dispute concerning fields, vineyards, or money, that they avoid perjury let two be chosen to fight, and decide the cause by duel" (Grimm, *Rechtsaltert.*, p. 928). In England, after the Conquest, trial by combat superseded other legal ordeals, which were abolished in the time of Henry III. A lord often sent his man in his stead to such combats, and priests and women were ordinarily represented by champions. The wager of battle died out so quietly in England without being legally abolished that in the court of king's bench in 1818 it was claimed by a person charged with murder, which led to its formal abolition (*Ashford* v. *Thornton* in Barnewall and Alderson 457; *see* details in H. C. Lea, *Superstition and Force*, ii.). A distinct connection may, however, be traced between the legal duel and the illegal private duel. (*See* DUEL.)

(E. B. T.; X.)

ORDER, a row or series, hence grade, class or rank, sequence or orderly arrangement (Lat. *ordo*, rank, arrangement). For its various meanings *see* MINISTRY, THE CHRISTIAN; MONASTICISM; KNIGHTHOOD AND CHIVALRY; ORDER IN COUNCIL; BILL OF EXCHANGE.

For technical mathematical uses of "order" *see* NUMBER; CURVE; SURFACE; DIFFERENTIAL EQUATION.

ORDER, (1.) in classic architecture, a column or pilaster, with its base, shaft and capital, and the entablature (*q.v.*) above it (sometimes called epistyle), consisting of architrave, frieze and cornice, considered as a single architectural feature; the "orders" are systematized classifications of five different types, Tuscan, Doric, Ionic, Corinthian and Composite. (2.) In mediaeval architecture, in an arched door or other opening, where the opening is larger on the outer face of a thick wall than on the inner face, one of the breaks in the steps in the thickness of the wall, consisting of an arch above and a pier on each side, by which the transition from larger exterior to smaller interior opening is effected.

Classic Orders.—Greek architecture had developed three easily recognizable classes of order which had been adopted by the Romans, with modifications, by the middle of the 1st century, B.C. It was natural, therefore, that Vitruvius, in his remarkable treatise on architecture (last quarter of 1st century, B.C.) should have attempted to give rules for the construction of these three orders. Moreover, as the Etruscan architects had developed a simple order of their own, using a wooden entablature, he added a section dealing with that. With the republication of Vitruvius in the second half of the 15th century, he was at once hailed as the authority on all things architectural, and architectural writers of the later Italian Renaissance attempted to imitate him by giving ideal rules for the orders, which should be efforts to reconcile the standards of Vitruvius with the many varying examples of Roman work that they knew. They added as a fifth order the Composite type of capital. The two most famous of these Renaissance compilations, those of Vignola (Giacomo Barocchio, or Barozzi), published in 1563, and Palladio (1570), exerted a tremendous influence over 17th and 18th century architecture throughout Europe, and gave rise to the idea that these compilations were not merely statements of average usage, but rules to be absolutely followed, an idea contradicted by the architectural work of the two authors themselves. Lacking knowledge of Greek remains, and of the structural systems and details of Etruscan temples, the Tuscan order, which they described, is merely a simplified Roman Doric. Their passion for regularization showed also in the fact that they specify a definite pedestal and even a definite baluster as a part of each order. Various 18th century and modern architectural writers have attempted to simplify the order descriptions of Vignola and Palladio, and have thus perpetuated the Renaissance myth of the immutability of the orders. In general, Vignola's work was followed in France and Palladio's in England. The orders, as thus systematized, are as follows:—

Tuscan.—This is the simplest of the orders. It is characterized by a column seven diameters high, the capital and base each occupying one-half the diameter in height. The base consists of a plain, square plinth (*q.v.*) with a large torus (*see* BEAD-MOULDING) and a fillet above. The capital has an astragal (*q.v.*) at the top of the shaft, a necking (*q.v.*), which is merely a short continuation of the line of the column, and above that an echinus (*q.v.*) consisting of a simple ovolo (*q.v.*) or quarter round with a fillet below it, and carrying a simple, square abacus (*q.v.*). The entablature, as in all the orders, is supposed to be one-quarter of the height of the column, and consists of a plain architrave (*q.v.*), or lower member, with a simple square projection or taenia (*q.v.*) at the top, a plain frieze, or central member, and a cornice with a single moulding as a bed-mould (*q.v.*), an undecorated corona (*q.v.*) or projecting rectangular portion, and a cymatium (*q.v.*) or crowning moulding that is an ovolo.

Doric.—The column is eight diameters high, and carries 20 flutes, separated by arrises or sharp edges. The base has two toruses, the lower one larger than the upper, and the capital is given a projecting moulding at the top of the echinus and additional fillets or an astragal below the ovolo. The necking is ornamented with eight rosettes. The achitrave in the entablature is sometimes given two faces, the upper one projecting slightly, being wider than the lower. The taenia is decorated with a moulding and beneath each triglyph of the frieze, a small block called a regula (*q.v.*), with six guttae, or small conical forms on its under side. The frieze is ornamented by triglyphs, or vertical projections decorated with a series of vertical grooves. Between each two triglyphs is a square metope (*q.v.*), a plain surface carrying sculpture; a triglyph is arranged over the centre of each column. Two forms of cornice are described; the denticular, in which the chief feature of the bed-mould is a row of dentils or little projecting blocks, and the mutular, in which the under side of the corona is decorated with projecting blocks, one over each triglyph. In both cases guttae are used on the soffit or under side of the cornice. In the denticular cornice they ornament square panels over each triglyph; in the mutular, the under side of the projecting blocks or mutules. The cymatium consists either of a cavetto or a cyma recta, a moulding of double curvature, the convex portion below and concave portion above.

Ionic.—The column is nine diameters high. The base is of the type known as an Attic base with a plinth carrying two toruses, separated by a scotia or hollow moulding. The capital is characterized by the volutes (*q.v.*) or spiral scrolls that are the ends of a band (usually consisting of a hollow portion called a canalis, and a raised fillet) represented as passing horizontally across the top of the echinus, and winding up on either side in a volute or helix. The capital is thus rectangular, and the volutes of the two faces of the capital are connected by a generally cylindrical form known as a cushion. This sometimes takes the form of two vases, end to end, and is sometimes decorated with leaves. The echinus, of ovolo profile, is carved with the egg and dart (*q.v.*), and where, as it follows the curve of the column, it disappears behind the rolls of the volutes, a little half anthemion (*q.v.*) or radiating petalled form hides the intersection. The entablature has an architrave decorated with either two or three bands, each wider and projecting farther than the one below it, and a taenia ornamented with mouldings. The frieze is plain, and the cornice has a bed-mould of three parts—a dentil band separating two mouldings, the lower one a cyma reversa, the upper one an ovolo. The cymatium is a cyma recta with a smaller cyma reversa below it.

Corinthian.—The column is ten diameters in height, and the base resembles the Attic base of the Ionic order, with the exception that in the centre of the scotia there is a third, small torus, with fillets above and below. The capital is much deeper than in the Doric and Ionic orders, and consists of a generally bell-shaped core, carrying a moulded abacus whose sides are concave, so that the corners project. At the bottom of the bell of the capital is an astragal, and the surface of the bell is surrounded by a characteristic decoration of acanthus leaves and scrolls. The lower two-thirds has 16 acanthus leaves in two rows of eight each, the centres of the upper leaves being placed between the joints of the lower leaves. Between the leaves of the upper row are cup-shaped leaf ornaments known as cauliculi (*q.v.*), which grow on stalks, and out of each cauliculus grow two stalks, one large and one small, so arranged that the voluted ends of the two adjacent large scrolls meet under each projecting corner of the abacus.

while the two adjacent smaller stalks come together under the centre of each concave abacus space; above their juncture is a large rosette. The architrave of the entablature, like that of the Ionic, has three bands and a moulded taenia, but additional richness is given by tiny mouldings between the bands. The frieze is plain, though sometimes pulvinated, or given a profile of convex curve. The cornice resembles that of the Ionic order with the addition of the band of modillions (*q.v.*). These are small scrolled brackets under the soffit of the corona, and are usually decorated on the sides with S-scrolls and on the bottom and front face with acanthus leaves. They are crowned by a little cyma reversa moulding. The soffit of the corona is panelled between the modillions, and in each panel there is a rosette.

Composite.—This is, in reality, merely a varied form of the Corinthian order and, like it, the column is fluted and ten diameters high. A special base is given to it by doubling the small torus in the centre of the scotia between the two large toruses. The capital, its main distinguishing feature, consists of a bell surrounded with 16 acanthus leaves, in two rows, arranged similarly to those of the Corinthian capital.

But above them, instead of the scrolls and cauliculi, there are volutes, like those of the Ionic order, except that they are on the four sides of the capital and brought out at an angle at the corners. In the bed-mould of the cornice, large rectangular blocks take the place of the modillions, and in some codifications a part of the bed-mould as well.

Scamozzi Ionic.—In addition to the five orders listed above, certain authorities have given a variant of the Ionic order, known as the Scamozzi Ionic after the Italian architect (Vincenzo Scamozzi, 1552–1616), who first codified it. Its chief difference from the ordinary Ionic order is in the fact that its capital is four-sided, the volutes occurring on all four faces, and at the corners brought out in an angle, so that the abacus above is concave-sided, like the Corinthian.

Moreover, the bands forming the volutes are not connected on each face by a horizontal line, but curve over and down into the top of the echinus; in the empty space thus left in the centre of each face there is a rosette. At times garlands connect the centres of the volutes.

Purpose.—The object of each codification of the orders is to furnish exact proportionate dimensions for every small feature, so that given the diameter of the column, the entire order may be constructed mechanically. The rules of all these attempted codifications vary slightly.

Origins.—The origin of the earliest of the orders, the *Doric*, was, at least partially, in wooden construction and seems to be a purely Dorian, or at least Hellenic, development, as far as the entablature is concerned. The question of the column is, however, more complex. In the Aegean culture, columns were common and their capitals consisted of a square abacus with a convex echinus below. The resemblance of this type, shown not only in wall paintings, but also in certain remains of the stair hall of the palace at Cnossus (*c.* 1500 B.C.), the column on the Lion Gate and those of the tholos of Atreus, both at Mycenae (both *c.* 1200 B.C.) to primitive Greek Doric capitals, is too close to be mere coincidence. On the other hand, Aegean columns universally tapered downward, were principally of wood and sometimes extremely slender in proportion, those at the tholos of Atreus being almost 11 diameters high, while those of the primitive Doric have an extreme taper upward and are short and stumpy. Moreover, the Aegean entablature, as shown in wall paintings, is entirely different from the Greek Doric, its chief features being round, projecting beam ends, close together, supported on a simple girder. The Greek Doric entablature has forms which seem to indicate a wooden origin, but one based on a different system of construction from that employed by the Aegean peoples. The architrave represents the original wooden beam running from post to post; the taenia, a board above this, to give a perfect bearing for the cross beams. The triglyphs are the ends of these cross beams, held in place by pegs through the taenia board, represented by the guttae. The metopes are merely closing boards between the beams. The mutules, or sloping blocks on the under side of the projecting cornice corona, represent the under sides of slanting roof rafters, supported on a timber or plate, above the cross beams, and perhaps decorated on the under side by flat boards or wooden pegs whose heads become the guttae in the stone version.

It is known that the primitive temple of Hera, at Olympia, had, originally, wooden posts, which were replaced from time to time during historic times, as they rotted, by stone columns. Nevertheless, the extreme taper and squat proportions of early Doric columns seem to demand an origin of masonry, and especially a masonry made of small stones. The origin would thus appear to be triple; the shaft, from early rubble construction; the capital borrowed and adapted from Aegean sources; while the entablature is an interpretation in stone of traditional Dorian wood construction. The earliest example known of the Greek Doric order is that of the temple at Corinth, probably dedicated to Apollo, which must be as early as the 6th century, and may go back to the 7th. Other early examples exist at Segesta, Selinus, Girgenti and Paestum, which are all of uncertain date, but undoubtedly prior to the Persian wars. Two of those at Selinus may go back to the 7th century B.C. The latest ancient example is that of the Agora gate at Athens (12 B.C.–A.D. 2). During these 700 years the basic elements of the Doric order did not change; the development, which was great, was only in the gradual refinement of every feature, and a continual experimentation in the exact treatment of each form, to give the desired result. Columns became taller and more slender, and the entasis (*q.v.*), or curved taper, more and more delicate. The ovolo of the echinus changed from the obese projections of Corinth and Paestum to the extremely refined and subtle curves of the Periclean period. The entablature, which in early examples had been almost half the height of the column, was gradually reduced in size, till in the Parthenon it is approximately one-fifth. The Greek Doric order was probably, in all cases, richly decorated in colour, so that its present appearance of austerity and over-restraint is illusory.

The *Roman Doric* order has plainly a double origin. The differences between it and the Greek Doric are not due entirely to Roman inability to appreciate the subtleties of Greek work, but merely to the fact that the Etruscans, and perhaps the north Italians, generally, had, at a very early period, developed a column and entablature of their own, with a long, slender, wooden column, having an ovolo echinus similar to the Aegean, and an entablature of wood, sometimes decorated with terra-cotta appliqués. It is this Etruscan column and entablature which Vitruvius endeavoured to describe, and which was misunderstood by the Renaissance, so that the name Tuscan came to be applied to a simplified Doric. It was also the origin of the unfluted, Roman Doric column, with its simple, quarter round echinus. To this the Romans applied an entablature embodying certain Greek features. In Roman architecture, the use of the Doric was reserved for small scale columns, as in many of the house courtyards at Pompeii (the forum colonnade at Pompeii was originally Greek), and to engaged or attached columns between arches. When used on a larger scale it was frequently much modified. Thus, in the temple of Hercules at Cori (attributed to Sulla, *c.* 80 B.C.), a base has been added, consisting of a single torus, but without a plinth. The entablature is extremely delicate in proportion, and the capital profile approximates that of the Greek Doric. A triglyph occurs on the corner, as in Greek work. In the theatre of Marcellus, at Rome (completed 13 B.C.), there is no base, and in the Colosseum (A.D. 80) there are no triglyphs. The Renaissance codifiers, however, took these two as the most typical, and their order is a sort of average between them. Another Doric order, coming originally from Albano, has no base except a fillet with apophyge, and the mouldings of the capital are richly carved. Other Roman Doric orders of extreme richness, in which the echinus of the capital is formed by a cyma recta instead of an ovolo are those from a temple on the Aventine, probably of the 2nd century A.D., and one from the baths of Diocletian (A.D. 305).

The *Ionic* order had manifestly an Asiatic origin. Its capital is a development from stele (*q.v.*) capitals of Phoenicia and the eastern end of the Mediterranean, which were themselves based

originally on the tri-lobed lotus. A famous example of the primitive type was found at Neiandreia, and another in Messa, in Lesbos. Excavations on the Acropolis at Athens, and elsewhere, have revealed many examples of the intermediate stages between the flaring volutes and awkward proportions of the early type and the refined perfection of the developed Ionic of the temple of Nike Apteros (probably between 440 and 410 B.C.), or the Erechtheum (407 B.C.). The characteristic features of the Greek Ionic order as found in Greece itself are the bold size and exquisite curvature of the volutes, the remarkable perfection of carved ornament that decorates the whole, and the variety of the types of base found.

The treatment of the order at the corners of a portico was difficult. The corner capital was formed with volutes on two adjacent, rather than two opposite, faces; where they met, the volutes were curved out at an angle together under the corner of the entablature. This created a new difficulty on the opposite corner, inside the colonnade, as it brought two half volutes together in an awkward way. It was this difficulty that led to a development of a variation of the Ionic capital with four faces the same and angle volutes. The most beautiful Greek example is that of the temple of Apollo at Bassae, designed by Ictinus, the architect of the Parthenon (probably *c.* 425 B.C.). In this the columns of the interior of the cella are connected by short walls to the exterior wall, and evidently, in order to have them present the same decorative face toward the entrance as toward the narrow nave between them, Ictinus adopted a four-sided Ionic capital.

A much more virile Ionic at enormous scale was developed in the great Hellenistic temples of the Asia Minor coast, such as those at Miletus and Priene. The archaic temple at Ephesus had set the style as early as the 6th century B.C., and its rebuilding, shortly after 350 B.C., by Dinocrates, while keeping certain of the more archaic features, such as the sculptured drums of the lower portions of the columns, was in the complete new Hellenistic Ionic style. The characteristics of this are: (1) a capital with volutes relatively smaller than in Athenian examples; (2) a cornice whose most striking feature was the very large dentils of the bed-mould, so large and so widely spaced, in fact, that in appearance they became almost separate brackets.

The *Roman Ionic* was based more on the Asia Minor than on the Attic types. Its details, throughout, were heavier than the usual Greek type. This heaviness appears even in the temple of Fortuna Virilis, which is not only the earliest purely Roman Ionic order, but also probably the earliest building in Rome in a good state of preservation to-day. It is variously attributed to the beginning of the 2nd and the beginning of the 1st century B.C. In general, the three chief differences between the Greek and Roman Ionic orders are: (1) the band connecting the volutes is perfectly horizontal, both at top and bottom, in Roman examples, and without the central dip of most Greek capitals; (2) the relative height and importance of the bed-mould of the cornice is much greater in the usual Roman examples. This is true, even in the most delicate and the most Greek of the monumental Roman orders—that of the theatre of Marcellus; (3) the base of the Roman order has, almost always, a square plinth as its lowest member. An exceptional type of Roman Ionic order is that of the temple of Saturn, on the Roman forum, the ancient treasury of Rome, whose ugly heaviness is characteristic of its date, after the great fire of A.D. 283.

Whatever the date of the original invention of the *Corinthian* order, it did not come into general use until the middle of the 4th century B.C. The capital perhaps owes its bell shape to Greek travellers' memories of the campaniform capitals of Egypt. But the Greek expression of this form is characteristically gracious. (For the charming Greek myth of its creation, *see* Vitruvius, Bk. IV.) Certainly the simplest form of the capital, in which a bell, decorated with flat and delicately pointed leaves, close together, has its lower portion surrounded by eight boldly curving acanthus leaves, suggests a basket around the bottom of which an acanthus plant has grown, as the myth states. The most famous example of this simple type decorated the "Tower of the Winds," at Athens, originally built in the 1st century B.C. to contain a water clock. The more complicated type, which is well represented by the exquisite capital of the tholos at Epidorus (middle 4th century B.C.), had two rows of leaves below and corner and central scrolls above. An even simpler form of the same type of capital, found alone in the ruins of the temple at Bassae, may be as early as the temple itself. The most popularly known example of the Greek Corinthian order, is that of the little choragic monument of Lysicrates, at Athens (335 B.C.).

The extremely lavish capital is, however, exceptional in many ways, and its silhouette unpleasantly broken. The existing columns and capitals of the great temple of Zeus at Athens were originally considered to be duplicates of the capital that Sulla took to Rome, and which served as a model for early Roman Corinthian. It is now known that the present remains are of the time of Hadrian. The order is, therefore, Roman, and not Greek. The Greeks never developed a separate entablature for the Corinthian order, using, instead, one of purely Ionic type; that of the tholos at Epidaurus owes its peculiar flat cornice to the fact that it was an interior order, rather than to any attempt to develop special entablature forms to crown the Corinthian capital.

Roman tradition found the origin of the *Roman Corinthian* order in a capital of the Athenian temple of Zeus, which Sulla brought with him to Rome. Long before that date, however, the Etruscans had been using forms Corinthianesque in type, and Pompeii also shows capitals which approach the Corinthian. In any case, the use of the Corinthian order on a monumental scale, as the Roman order *par excellence,* was well established by the time of Augustus, and the temple of Mars Ultor, dedicated in 2 B.C. as part of the forum of Augustus, and the portico of Octavia, of approximately the same date, both have completely developed magnificent Corinthian orders. It is noteworthy that in these the modillion (*q.v.*) had already reached a complete form. New light on the origin of this new feature which transformed the Ionic entablature into the Corinthian and which is the great Roman contribution to the development of the orders, is furnished by fragments of the order of the basilica Aemilia (dedicated 29 B.C.). These fragments are of the typically pure Augustan type, and therefore, probably due to this date and not to any of the succeeding rebuildings, and indicate a cornice with modillions which are deeper at the outer end than at the inner; that is, they slope down like the Doric mutules. Their outer ends are, however, scrolled.

The Roman Corinthian order is found in infinite variations. In certain small examples in tombs, gateways and the like, its proportions are thick and stumpy. as in the triumphal gateway at Saintes, of the time of Tiberius. In other cases it is extremely slender, as in the arch of Augustus at Susa. At times there are no modillions in the cornice, as in the temple of Antoninus and Faustina, at Rome (A.D. 141), and in the great temple of Venus, at Rome (A.D. 135), rebuilt by Maxentius (after 307). The modillions are replaced by the square, projecting blocks adopted by the Renaissance for the Composite order. Moreover, many types of capital exist. In some the two rows of leaves are at approximately equal height and kept tight to the bell, so that the effect is very vertical. In others, the lower row of leaves is made tall, so that the projecting leaf ends of both rows are close together and project markedly, giving almost the effect of a wreath around the capital. In other smaller examples, such as many at Pompeii, the ornament is hardly more than a frosting of the stucco surface of the bell. In the colonnade of the temple of Apollo, at Pompeii (rebuilt *c.* A.D. 63), a Doric entablature is supported by Corinthianesque columns. In some examples, rampant animals take the place of the corner volutes, as in the order of the temple of Concord, at Rome (A.D. 10) and in the capitals of the Roman gateway at Eleusis, in Greece (1st century A.D.). Another type, common in pilasters, substitutes for the cauliculi, with their double scrolls, an S-scroll at each side, turned in to the centre below and out to the corners above. This type gave rise to many 15th century early Renaissance capitals.

The most characteristic examples of the best type of the Roman Corinthian order are those of the round temple of Vesta.

at Tivoli (probably Augustan); the portico of the Pantheon, perhaps from the original building by Agrippa (27 B.C.); the interior of the Pantheon (A.D. 115–125); the portico of Octavia; the temple of Castor and Pollux on the forum (either of the rebuilding under Tiberius A.D. 6, or of the time of Hadrian), which is remarkable for the decoration of the middle band of the architrave and for the large, interlacing, central volutes of the capital; and that of the temple of Jupiter at Baalbek in Syria (time of Hadrian). An interesting order in brick and terra-cotta, evidently never stuccoed, is a doorway from an ancient Roman police station in Rome (early 3rd century); a more elaborate type of cut brick Corinthian with octagonal columns recessed into the wall is in the tomb of Annia Regilla (late 2nd century).

The *Roman Composite* order was actually only one of many variations of the Corinthian, and its erection into another order is a purely Renaissance idea. Vitruvius makes no mention of it and the earliest example known is one from a small garden pavilion in a house court recently (1928) excavated in Pompeii; an early monumental type is that of the arch of Titus, at Rome (completed A.D. 81), in which the exquisite composite capitals carry a normal Corinthian entablature. The bold richness of this type of capital was particularly popular during the later empire and the most magnificent example, remarkably delicate in execution for its late date, is one in the baths of Caracalla (211–216).

Renaissance.—During the middle and late 15th century in Italy and the early 16th century in France, the early Renaissance architects developed modified Corinthianesque orders of the most exquisite delicacy, in connection with doors, tombs and the like. The most characteristic feature of these orders is the general use of S-scrolls instead of volutes and cauliculi, and the use frequently of only small leaves beneath them at the corners of pilaster capitals. In the working out of the details of capitals of this type, the personalities of such sensitive designers as the Della Robbias, Desiderio da Settignano (1428–64) and Mino da Fiesole (1431–84) achieved some of their most characteristic and delicate expression. At times dolphins, birds and even cherubs' heads replaced the scrolls under the cornice of the capital. The entablatures of these orders are almost always without modillions, but characterized by a jewel-like delicacy in the carving of the ornamented mouldings. In the arrangement of this there is the greatest variety. During the high and late Renaissance the orders tend to become more normal, but little strict archaeology is found and much individuality of design is still present. The work of B. Peruzzi (1481–1537), of D. Bramante (1444–1514), of Vignola and of Palladio is particularly noteworthy. Typically Renaissance variations are rusticated orders like those in the gates of Verona by San Michele (1530) and the banded columns developed by Philibert Delorme for the Tuileries in Paris (1564), and followed in the Grande Gallerie (1578) and twisted columns like those of Bernini's baldacchino in S. Peter's at Rome (1633).

During the Baroque period, especially in Spain, all kinds of forms were used which approximate the orders, but are so broken up and contorted, and so varied in detail, that they can be assigned to no definite classification.

The 20th century has seen a reaction against the archaeological correctness of orders of the revival period. Orders, where occurring, are treated with the utmost freedom, and those styles seem most popular in which a like freedom prevailed, such as the late Georgian style of the Adam brothers, and American colonial, with its slimness and attenuation. In so-called modernist work, the order tends to pass from use as a superfluous ornament. In exceptional cases, however, especially in Scandinavia, extremely free and modified orders are still used, as in the concert hall at Stockholm, by Ivar Tengbom, and in America in portions of the interior of the Nebraska State capitol by B. G. Goodhue and the Goodhue associates.

ORDERIC VITALIS (1075–*c.* 1142), the chronicler, was the son of a French priest, Odeler of Orleans, who had entered the service of Roger Montgomery, earl of Shrewsbury, and had received from his patron a chapel in that city. Orderic was sent at the age of five to learn his letters from an English priest, Siward by name, who kept a school in the church of SS. Peter and Paul at Shrewsbury. When eleven years old he was entered as a novice in the Norman monastery of St. Evroul en Ouche. Orderic did not know a word of French when he reached Normandy; his book, though written many years later, shows that he never lost his English cast of mind or his love of England. His superiors rechristened him Vitalis, after a member of the legendary Theban legion. But in the title of his Ecclesiastical History he prefixes the old to the new name and proudly adds the epithet *Angligena*. He became a deacon in 1093, a priest in 1107. He left his cloister on several occasions, and speaks of having visited Croyland, Worcester, Cambrai (1105) and Cluny (1132). For many years he appears to have spent his summers in the scriptorium. His superiors (at some time between 1099 and 1122) ordered him to write the history of St. Evroul. The work grew under his hands until it became a general history of his own age. St. Evroul was a house of wealth and distinction. War-worn knights chose it as a resting-place of their last years. It entertained visitors from southern Italy, where it had planted colonies of monks, and from England, where it had extensive possessions.

Thus Orderic, though he witnessed no great events, was often well informed about them. His narrative gives us much invaluable information for which we should search the more methodical chroniclers in vain. He throws a flood of light upon the manners and ideas of his own age; he sometimes comments with surprising shrewdness upon the broader aspects and tendencies of history. His narrative breaks off in the middle of 1141, though he added some finishing touches in 1142.

The *Historia ecclesiastica* falls into three sections. (1) Bks. i., ii., which are historically valueless, give the history of Christianity from the birth of Christ. After 855 this becomes a bare catalogue of popes, ending with the name of Innocent I. These books were added, as an afterthought, to the original scheme; they were composed in the years 1136–1141. (2) Bks. iii.–vi. form a history of St. Evroul, the original nucleus of the work. Planned before 1122, they were mainly composed in the years 1123–1131. The fourth and fifth books contain long digressions on the deeds of William the Conqueror in Normandy and England. Before 1067 these are of little value, being chiefly derived from two extant sources, William of Jumièges' *Historia Normannorum* and William of Poitiers' *Gesta Guilelmi*. For the years 1067–1071 Orderic follows the last portion of the *Gesta Guilelmi*; hence this is of the first importance. From 1071 he begins to be an independent authority. But his notices of political events in this part of his work are far less copious than in (3) Bks. vii.–xiii., where ecclesiastical affairs are relegated to the background. In this section, after sketching the history of France under the Carolingians and early Capets, Orderic takes up the events of his own times, starting from about 1082. He has much to say concerning the empire, the papacy, the Normans in Italy and Apulia, the First Crusade (for which he follows Fulcher of Chartres and Baudri of Bourgueil). But his chief interest is in the histories of Duke Robert of Normandy, William Rufus and Henry I. He continues his work, in the form of annals, up to the defeat of Stephen at Lincoln in 1141.

The *Historica ecclesiastica* was edited by Duchesne in his *Historiae Normannorum scriptores* (Paris, 1619). This is the edition cited by Freeman and in many standard works. It is, however, inferior to that of A. le Prévost in five vols. (*Soc. de l'histoire de France*, Paris, 1838–55). The fifth volume contains excellent critical studies by M. Leopold Delisle, and is admirably indexed. Migne's edition (*Patrologia latina*, clxxxviii.) is merely a reprint of Duchesne. There is a French translation (by L. Dubois) in Guizot's *Collection des mémoires relatifs à l'histoire de France* (Paris, 1825–1827); and one in English by T. Forester in Bohn's Antiquarian Library (4 vols., 1853–56). In addition to the *Historia* there exists, in the library at Rouen, a manuscript edition of William of Jumièges' *Historia*

Normannorum which Leopold Delisle assigns to Orderic. (*See* this critic's *Lettre à M. Jules Lair* [1873].) (H. W. C. D.; X.)

ORDER IN COUNCIL, in Great Britain, an order issued by the sovereign on the advice of the privy council, or more usually on the advice of a few selected members thereof. It is the modern equivalent of the mediaeval ordinance and of the proclamation so frequently used by the Tudor and Stuart sovereigns. In practice it is only issued on the advice of ministers of the Crown, who are, of course, responsible to parliament for their action in the matter. Orders in council were first issued during the 18th century, and their legality has sometimes been called in question. Consequently in several cases parliament has subsequently passed acts of indemnity to protect the persons responsible for issuing them, and incidentally to assert its own authority. At the present time the principle seems generally accepted that orders in council may be issued on the strength of the royal prerogative, but they must not seriously alter the law of the land.

The most celebrated instance of the use of orders in council was in 1807 when Great Britain was at war with France. Orders in council are used to regulate the matters which need immediate attention on the death of one sovereign and the accession of another.

In addition to these and other orders issued by the sovereign by virtue of his prerogative, there is another class of orders in council, viz., those issued by the authority of an Act of parliament, many of which provide thus for carrying out their provisions. At the present day orders in council are extensively used by the various administrative departments of the government, who act on the strength of powers conferred upon them by some Act of parliament. They are largely used for regulating the details of local government and matters concerning the navy and the army, while a new bishopric is sometimes founded by an order in council. They are also employed to regulate the affairs of the crown colonies, and the lord-lieutenant of Ireland, the viceroy of India, the governor-general of Canada, and other representatives of the sovereign may issue orders in council under certain conditions.

In times of emergency the use of orders in council is indispensable to the executive. The Regulation of the Forces Act 1871 empowers the government in a time of emergency to take possession of the railway system by the issue of such an order; and during the World War the use of orders in council was frequent.

ORDERS OF KNIGHTHOOD: *see* KNIGHTHOOD AND CHIVALRY.

ORDINANCE, in mediaeval England, a form of legislation. The ordinance differed from the statute because it did not require the sanction of parliament, but was issued by the sovereign by virtue of the royal prerogative, although, especially during the reign of Edward I., the king often obtained the assent of his council to his ordinances. Legislation by ordinance was common during the reigns of Henry III. and Edward I. when laws were issued by the king in council or enacted in parliament indifferently. Both were regarded as equally binding. In 1389 the Commons presented a petition to King Richard II. asking that no ordinance should be made contrary to the common law, or the ancient customs of the land, or the statutes ordained by parliament. For this and other reasons this form of legislation fell gradually into disuse, becoming obsolete in the 15th century. The modern equivalent of the ordinance is the order in council (*q.v.*), but in the crown colonies legislation is both by orders in council and by local ordinance issued by the governor with the assent of his council.

In the 17th century the use of the word ordinance was revived, and was applied to some of the measures passed by the Long Parliament, among them the famous Self-denying Ordinance of 1645.

ORDINANCE or **ORDONNANCE,** in architecture, a composition of some particular order or style; not restricted to columnar composition, the term applies to any kind of design which is subjected to conventional rules for its arrangement.

ORDINARY, in canon law, the name commonly employed to designate a superior ecclesiastic exercising "ordinary" jurisdiction (*iurisdictionem ordinariam*), *i.e.,* in accordance with the normal organization of the Church. It is usually applied to the bishop of a diocese and to those who exercise jurisdiction in the name of the bishop or by delegation of his functions. In English law, however, the term ordinary is now confined to the bishop and the chancellor of his court. The pope is the *ordinarius* of the whole Roman Catholic Church, and is sometimes described as *ordinarius ordinariorum.* Similarly in the Church of England the king is legally the supreme ordinary, as the source of jurisdiction.

In England the only instance of the term ordinary being employed in its civil application was that of the office of judge ordinary created by the Divorce Act of 1857, a title which was, however, only in existence for about 18 years owing to the incorporation of the divorce court with the high court of justice by the Judicature Act, 1875. But in Scotland the ordinary judges of the inner and outer houses are called lords ordinary, the junior lord ordinary of the outer house acts as lord ordinary of the bills, the second junior as lord ordinary on teinds, the third junior as lord ordinary on exchequer causes. In the United States the ordinary possesses, in the States where such an officer exists, powers vested in him by the constitution and acts of the legislature identical with those usually vested in the courts of probate. In South Carolina he was a judicial officer, but the office no longer exists, as South Carolina has now a probate court.

ORDINATE: *see* CO-ORDINATES.

ORDNANCE. One definition approaching obsolescence would limit "ordnance" to great guns, naval or military, as distinct from small arms and other lesser types of war matériel. However, according to later usage the term embraces almost all varieties of weapons, projectiles, agents and devices, together with the apparatus necessary to activate or discharge these, which one people employs in an attempt to enforce its will upon another. (Excepted are certain atomic and chemical and all of the available bacteriological instrumentalities.) To satisfy both interpretations, the limited definition will be followed rather closely in the historical material covering the first four periods of ordnance development as described below, while the more comprehensive definition will be invoked for the last period (1940 and later).

The evolution of ordnance may conveniently be divided into a sequence of periods or epochs, as follows:

1. Appearance of gunpowder in mid-13th century to the first solid-cast cannon in the early 18th century—about 1713.
2. Early 18th century to end of smooth-bore era in mid-19th century—about 1845.
3. Mid-19th century to end of black powder era in early 1880s.
4. Early 1880s to about 1940—the smokeless powder era.
5. Post-1940—the atomic-electronic era.

FIRST PERIOD (c. 1248–c. 1713)

This period marks the appearance of gunpowder and artillery in the western world and the manufacture of cannon of increasing size and bore, both breech- and muzzle-loading, first from small, hollow bronze castings, then from welded rods of wrought iron by a "built-up" process, and still later from hollow castings, some of tremendous size. The era ended with the introduction of methods of producing solid gun castings and boring these to the required internal diameters.

Obviously, the development of an engine which could hurl missiles to distances beyond those achieved by the "artillery" (*i.e.,* bows and arrows) of the ancients had to await the appearance of some new and powerful agent capable of the sudden release of a vastly greater amount of energy than that stored in the bowstrings, twisted ropes, stressed timbers and elastic metal strips which, operating on principles of tension and torsion, had for centuries motivated man's projectile weapons of war. That agent proved to be gunpowder. For generations authorities have argued as to when and where this mixture of carbon, sulphur and saltpetre (potassium nitrate) appeared upon the world scene. Claims of its very early use in the orient, prior indeed to the Christian era (*see* below), are numerous but unsubstantiated. As to artillery (cannon), author after author repeats the erroneous translation from a Persian version of the ancient Gentoo (Hindu) laws which was prepared in 1776 by N. B. Halhead of the Bengal civil service. His text reads: "The magistrate shall not make war with . . . cannon and guns, or with any other kind of firearms." Actually the original Hindu text says: "The king shall not slay his enemies in battle

with deceitful or barbed or poisonous weapons, nor with any having a blade made red-hot by fire or tipped with burning materials."

In like manner, many an unwary student has claimed for both gunpowder and cannon a false antiquity because of failure to recognize that over the years the same word often designates different (but commonly related) objects.

Thus we read (*see* C. H. Owen, *Elementary Lectures on Artillery*) that: "For some time after cannon were first employed, we constantly find 'artillery' signifying not only cannon but all sorts of engines of war . . . ." As an example of the semantic confusion that long existed, Roger Ascham, writing in 1571, says: "Artillerie nowadays is taken for two things, gunnes and bowes."

Lieut. Col. H. W. L. Hime in his *History of the Royal Artillery Regiment* writes that Jean Froissart, French chronicler and historian (1338–1410), in his original account of the battle of Crécy (1346) speaks of crossbows and their bolts (quarrels) as "artillery," but designates as "kanons" the guns which the British brought upon the field. Thus these relatively feeble new contrivances had evidently not yet attained at that time a stature warranting the application to them of the generic name for projectile weapons.

It is fruitless to speculate upon the exact date of the introduction of gunpowder into Europe, or of the first cannon which presumably were developed not too long afterward. Despite many and oft-repeated statements to the contrary, the best available information indicates that both of these appeared first in the western world and travelled thence eastward. None of the extensive works of Arab and Greek alchemists dating prior to the 13th century even mention saltpetre, gunpowder's basic ingredient. This leaves as the first authentic account of the composition of gunpowder a document written about 1248 by Friar Roger Bacon, the outstanding British scientist of his day. Obviously, however, the existence of gunpowder must have been known to a limited few somewhat earlier. That it was already widely known as an explosive agent within 20 years after Bacon first wrote of it is indicated by a passage in his *Opus Tertium* (1265–68) in which he refers to it as in use "... *in mundi partibus diversis*" (in divers parts of the world).

H. B. C. Pollard stated that the city of Ghent (Belgium) acquired a cannon in 1313. This claim is quite substantial. Hime offers in evidence of its validity a passage from a yearbook commenced by the municipality of Ghent in 1300 and maintained for more than 100 years. One entry for 1313 reads: "Item, in this year the use of *bussen* (guns) was first discovered in Germany by a monk." In another record maintained by the same city appear for 1314 various notes recording the shipment to England of "*bussen mit kruyt*" (guns and powder).

With respect to the first two of these manuscripts, the cleric referred to could hardly have been other than Berthold Anklitzen, better known as Berthold Schwarz, of Mainz, Ger., who was also a sometime resident of Freiburg. He is credited with having been the first to recognize and harness the propellent force of gunpowder.

About as debatable as the name of the inventor of artillery (for there are many who discount the above tale) is the date and place of its first use in battle. At any rate, we do not commence to come upon soundly documented records until after 1300. We have referred to the city of Ghent and its possession of a cannon in 1313. According to R. Schmidt, a prolific writer on arms and ammunition during the third quarter of the 19th century, artillery appeared in Europe according to the following time schedule: Belgium, 1313; Germany, 1324; Italy, 1326; England, 1327; Spain, 1331; France, 1338; Switzerland, 1371; Russia, 1389; and Sweden, 1400.

It seems evident that somewhere between 1300 and 1325 cannon were first employed in Europe upon the field of battle and that no authentic instance of their prior use anywhere has been established. In the British Isles they appear during Edward III's invasion of Scotland (1327) as recorded by Archdeacon John Barbour of Aberdeen (1316?–95). The first acceptable account of their employment by a British war vessel is given by H. Brackenbury as 1338.

Examining the nature of the artillery which figured in the first historically substantial instances of its use, what were its characteristics? One way to approach this problem is through a study of the projectiles which these crude pieces discharged. Obviously it would be but a simple step if the first of these missiles had developed directly from their immediate predecessors, the darts or quarrels of the crossbow. As a matter of fact, that is exactly what happened. The oldest surviving illustration of a cannon, from a manuscript dated 1327 belonging to Christ Church, Oxford, Eng., depicts a vaselike contrivance on a wooden stand with an arrow-shaped missile emerging from its muzzle (*see* fig. 1). Furthermore, one of the earliest French documents bearing on artillery, which dates from 1338, mentions this type of projectile, the overall weight of which has been estimated at about seven to eight ounces. From this we deduce the fact that the piece discharging it must have been truly minuscule, light enough to have been held and fired by the individual soldier. Indeed, authorities tell us that the difference in size between contemporary "field artillery" pieces on wheelless mounts and the hand guns carried and discharged by the early 14th-century soldier was negligible. Thus we find on an inventory of stores in the fortress of Artois in 1381 "seven stout cannon, four of these large, and three transportable by hand."

FIG. 1.—EARLY TYPE OF CANNON

The outlines of the piece shown in the Christ Church manuscript explain why early cannon were commonly described as *vasi* or *pots-de-fer* ("iron pots"), since its contours are identical with those of a modern vase; viz., bulbous base, narrow curving neck and flaring mouth. They likewise indicate its characteristics with respect to size, shape, manner of mounting and firing, better than words could accomplish. And despite the obvious unsuitability of an arrow-type projectile for discharge from a firearm (an unsuitability belied in some measure by the successful development more than 400 years later of harpoon guns for whale fishing), this unhandy combination continued in use for well over two centuries.

As to method of manufacture, the first artillery pieces seem to have been constructed of cast bronze or brass and were very small. Soon after, guns of wrought iron appeared, but not of cast iron since the technique of producing successful casts with ferrous metals did not develop until the 15th century. It reached England relatively late. Research by the British Iron and Steel institute fixes 1509 as the approximate date of the first iron cannon to be cast in that country. Wrought iron, because of its slag inclusions, was far from a perfect medium in which to work, but it was long employed for lack of something better, and with it guns of very substantial dimensions were produced. The usual practice was to arrange one or more layers of hand-wrought iron bars or rods side by side in a circle, then weld their abutting surfaces together like the staves of a barrel (whence the name "gun barrel"). To fill the interstices which remained, molten lead was often employed. Then, to give added strength and solidity, wrought-iron rings were driven onto the sheaf of welded bars so closely together from breech to muzzle as to cover entirely that which lay beneath. Since it was difficult to attach an integral breech piece to this open-ended affair, many cannon so constructed were made breech-loading (*see* below), though in some instances a hollow bronze cylinder, open at one end and closed at the other, was driven into the breech end of the welded barrel to serve as a powder chamber. Thus the enclosed end of the cylinder became the breech of a completed, muzzle-loading cannon. For the breechloaders, powder chambers were supplied by welding to the open breech of the barrel tube, a skeletonized cylinder of a diameter somewhat greater than that of the bore, cut away at the top and open at the forward end where it joined the barrel to become a rearward extension thereof. Into the cutaway top of this barrel extension, a movable, ready-loaded chamber (powder container) could be dropped. This was simply a hollow vessel closed at one end, with a handle attached for easy manipulation. The rear (closed) end of this cylinder abutted against the closed (breech) end of the welded-on barrel extension. The forward end lined up with the breech end of the barrel tube.

The ball was pushed into the open rear end of the barrel, then the movable powder chamber dropped into position behind.

Early nomenclature for firearms of all kinds was, as we have indicated, confused. The English words "cannon" and "gun" (the latter can be traced back to about 1350, the former at least to Froissart) derive respectively from the Latin *canna* (a tube) and *mangonel,* a powerful pregunpowder stone-hurling engine of war. Mortar has always been applied to a short, stubby cannon because of its resemblance, in its earliest forms, to the conventional vessel of the chemist and apothecary. "Bombard" was also used to describe early guns, large and small. Thus *bombardes à main* (hand bombards) are mentioned as in use at the siege of Bonifacio in 1420, while the diminutive form *bombardelle* appears in an earlier Italian manuscript of 1381. However, after the art of casting great guns was mastered during the last decades of the 14th century, "bombard" came gradually to apply only to large pieces of artillery now long obsolete. Today we still use it in its verb form —to bombard.

Corresponding early German designations for both hand guns and field artillery were first *bussen* and later *Büchsen.* Over the years the latter, like bombard, became associated solely with larger pieces (cannon) only to experience a final reversal of meaning so that for modern generations it came to mean (rifled) shoulder weapons alone. The French *coulevrine* (English, culverin) underwent a similar evolution (from indicating guns small and large, to large only). The latter meaning still obtains, though the particular type of cannon to which it was applied has been forgotten for centuries. In some Latin-speaking countries, the word for gun took such variant forms as *scopitus, schioppi, schiopetto, escopette,* etc. The last of these persists in the modern *escopeta,* the Spanish word for shotgun.

The illustration of the cannon which appears in the Christ Church manuscript would certainly seem to depict a cast rather than a built-up piece. And the material used was presumably brass or bronze rather than iron, because of the pre-existing experience of bell-founders in the use of the two former. This is confirmed by a Florentine record of 1326 which relates to the manufacture of darts, iron balls and *cannones de metallo.* Had iron been meant, *cannones de fer* would have been the designation. However, iron pieces (presumably of wrought-iron construction) were soon to appear, since only 13 years later (1339) a Florentine manuscript records the presence at Cambrai of five iron cannon and five of metal (*i.e.,* nonferrous types).

Based upon various studies to which we have referred, it seems reasonable to believe that early portable firearms were originally produced as muzzle-loading brass or bronze (gun metal) castings, and that heavier pieces for field or fortress use were likewise similarly fashioned. (Brass is a mixture of copper and zinc, bronze an alloy of copper and tin. Gun metal is a bronze containing usually nine parts copper and one of tin.) But before many decades had passed, the discovery of a method to produce built-up iron guns resulted in the wrought-iron pieces already described, both muzzle- and breech-loading. Again, by 1370 the art of working in bronze had progressed so far that the casting of guns with bore diameters which even today appears staggering was undertaken (*e.g.,* the famous "Dulle Griete" of 1382 with a bore of 25 in.; *see* fig. 2).

Some of these monstrous pieces were muzzle-loading, some breech-loading. Both varieties were used without carriages, being simply laid upon the ground with breech embedded (the earth absorbing the recoil) and muzzle elevated by wedges. So placed they were of course tactically immobile and, while suitable for the battering of a city wall or other structure, and perhaps the interdiction of a narrow defile, useless against a hostile line of battle in case the enemy commander chose to move his force out of their line of fire. Napoleon executed this simple manoeuvre at the battle of the pyramids (1798) when facing guns so emplaced by the Turks opposing him.

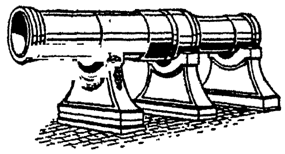

FIG. 2.—DULLE GRIETE, GHENT

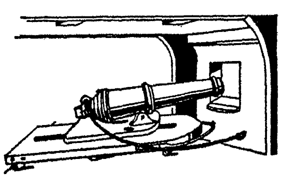
The performance of early cannon varied directly with certain factors; *e.g.,* their own inherent strength and the character of the powder and projectile employed. As to strength, cast guns were from the beginning subject to invisible flaws which could result in their bursting upon the 1st discharge—or the 1001st—and though great improvements in methods of construction were effected over the years, the low tensile strength of cast iron (15,000 lb. per square inch), brass (24,000 lb.) and gun metal (29,000–32,000 lb.), compared with the high tensile strength of wrought iron (48,000 lb.), cast steel (70,000 lb.) and the exceedingly high tensile strength of many carbon and alloy steels, indicates why the trend was constantly toward metals of superior tensile qualities. At the same time, the cheapness of cast iron as against all other metals available caused it to be universally adopted as soon as satisfactory and economical means of working it were developed and likewise to be retained in general use until well past the middle of the 19th century.



FROM H. GARBETT, "NAVAL GUNNERY"

FIG. 3.—32-POUNDER CARRONADE, A SHORT-RANGE NAVAL CANNON, LATE 18TH CENTURY

Two accidental bursts occurring during the reign of Henry V of England were considered important enough to be recorded in the *Proceedings* of the privy council for 1415. Another, in 1460, took the life of James II of Scotland. According to an account by Robert Lindsay in the *Chronicles of Scotland,* "This prince . . . did stand nearby quhair [where] the Artylliare were discharged, his thigh bone was dung [done] in two by ane piece of ane misformed gun that brake in the shuting: by the quhilk [by which] he was stricken to the ground and died hastilie thereafter." Another accident of note occurred in 1716 when Mathew Bagley, a gun founder to the British crown, undertook to cast two brass 24-pounders in London. As the metal for one of these was poured into the (doubtless insufficiently dried) mould, an explosion occurred which killed him and 20 others.

Fortunately for the gunners, the quality of gunpowder was so indifferent during the first century of the use of artillery that most cannon, feeble though they were, could handle large charges with safety. The powder employed was mixed on the field from its three basic ingredients, since if transported ready mixed, these were inclined to settle out into layers according to their respective specific gravities. Further, once blended, the resulting compound tended to give off a very fine but highly explosive dust, some of which managed to escape from containers no matter how tightly sealed. And since ignition of the first guns, large and small, was effected by applying to their touchholes torches, fiery embers, red-hot wires or the glowing ends of smouldering bits of cord, a real danger of explosion was ever present. By keeping the ingredients separated until ready for use, this hazard was avoided.

Methods of powder making advanced slowly. As late as 1360–62, we find records of mortars and pestles being used for compounding gunpowder in the Tower of London. One of the first forward steps involved increasing the percentage of saltpetre in the mixture, at the expense of the other two components. This gradually rose from about 41% (Bacon, 1248) to around 75%, becoming stabilized at that figure during the 18th century, with charcoal contributing 15% of the final 25% and sulphur the remainder.

This first variety of low-order explosive (as against high explosives developed during the 19th century) was known as "mealed" or "serpentine" powder. Being very finely divided as a result of careful trituration, serpentine tended to pack closely when rammed into a chamber and hence to burn slowly because of lack of interstices between its almost microscopic grains. On the other hand, if packed too loosely, much of the charge was likely to be expelled from the muzzle unburned. As a result, skilled loaders who knew how to pack it just right (*i.e.,* not too compactly and not too loosely) were soon much in demand and acquired the title of "master gunner."

If powder improved slowly this was also true of the guns that fired it. Indeed, they were structurally unequal to handling the

corned variety (*i.e.*, powder produced with ingredients intimately and permanently commingled in grains of substantial size—no longer an impalpable mixture). This had appeared prior to 1430, but, although gradually adapted to hand grenades and small arms, was not generally employed in cannon for another century. Fabricated in grains of various sizes, each size intended for a different type of weapon, it burned so quickly and completely because of easy propagation of flame across the large interstices between grains that two pounds of corned powder would do the work of three of serpentine. Thus, from the original formula which called for a propellent charge of serpentine equal in weight to that of the projectile, a gradual reduction from this 1:1 proportion to one of 2:3 took place upon the introduction of the corned type, while by 1740 it had still further decreased to 1:2. By 1860 it was down to 1:4, and it was held that "a charge of $\frac{1}{4}$ the weight of the projectile and a bore of 18 calibres [*i.e.*, a gun barrel 18 times as long as its inside diameter] is the most favourable combination that can be made in cannon, to obtain the greatest range with least strain to the carriage." (Calibre used in describing a cannon means diameter of bore. In its plural form, when applied to a single piece, it indicates barrel length, as above.)

After the art of casting cannon had become well established and guns so made had practically displaced those of the wrought iron, built-up type, the *modus operandi* for producing a big gun became fairly well standardized. Described in the simplest terms, this involved the fashioning (around a reinforcing iron bar) of a long cylinder of clay in the size and shape of the bore of the finished weapon. This in turn was inserted into another larger concentric and roughly cylindrical clay mould the inner surface of which, after clever reverse modelling around a dummy form which was broken up and removed upon serving its purpose, exhibited all the external contours of the piece to be completed. The space between, when filled with molten metal (which was sometimes cast upon the spot), became, once the clay forms were removed, the barrel of the gun. During its preparation, the outer cylinder was reinforced with all manner of materials; *e.g.*, iron, timber, earth and stone.

With the technique of casting guns of substantial size once mastered, no radical changes in methods of fabrication were recorded throughout this era, though constant improvements in details of construction naturally took place. (*See* table for catalogue of principal cannon of the 16th century.) Cast iron steadily increased in popularity but never fully displaced the nonferrous types despite the fact that as early as 1646 William Eldred, master gunner at Dover (England) had expressed the prevalent opinion that ". . . Iron Ordnance is better and more serviceable than brass."

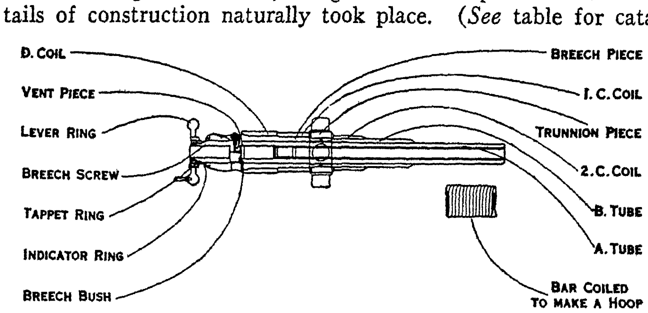


FIG. 4.—WROUGHT-IRON 40-POUNDER 35-CWT. GUN, MARK I (ARMSTRONG DESIGN)

Salient advances over this period included: (1) Wheeled carriages to replace crude sledges. (2) Substitution of the horse for the ox as a draught animal. (3) The pivoting of cannon on trunnions, thus permitting their ready adjustment to different elevations. This device served also to transmit the shock of recoil to the whole gun carriage instead of permitting it to work directly upon the heavy baulk which theretofore had constituted the rear element of a wooden framework in which the piece was supported —and transported. (4) Reversal of travelling position for field artillery from muzzle-foremost to breech-foremost. (5) Reduction in numbers of calibres and types of guns and carriages and general efforts toward simplification and standardization. (6) Locating the trunnions in the same plane as the axis of the bore instead of below this, as was the earlier practice. (7) Rifling the bores of artillery pieces was attempted, apparently without much success, as early as the mid-15th century; *i.e.*, soon after the practice had been adopted for certain types of shoulder weapons. Serious efforts to develop it are said to have been made by the Swiss Jean Maritz during the early 1700s, but manufacturing difficulties held it in abeyance for another 100 years and more. (8) Portable firearms and artillery had hardly become identified as separate types when a differentiation of the latter into three distinct varieties—mortar, howitzer and gun (or cannon)—commenced. These distinctions were still observed in the second half of the 20th century. The mortar is a short piece designed for high-angle fire at restricted ranges—to lob projectiles over hilltops onto an unseen enemy beyond; the howitzer with its longer barrel and less curving flight of projectile is employed for medium-range targets; and the gun, with longest barrel and flattest trajectory, seeks out targets as remote as may be attained by gunfire.

*Principal Guns of the 16th Century Compiled From What Appear to Be the Most Trustworthy Ancient Authorities**

Propellants of the First Period.—As already indicated, two major improvements in gunpowder took place during the first era, both contributing mightily to its increased effectiveness as a propellant. The first of these, the development of a method to produce powders in grains of varying sizes adapted to various purposes (in general, the larger the gun, the larger the grain it used) came toward the end of the first quarter of the 15th century; the second, which involved a gradual change in the proportion of gunpowder's three ingredients, was a continuing process, commencing soon after its introduction and not ending until during the 18th century.

First Period Projectiles.—The first cannon fired projectiles which were no more nor less than crossbow darts. These proved none too satisfactory, and search for improvements soon commenced. One material almost universally available was stone, so it was only to be expected that spherical stone projectiles would appear early upon the scene. They are mentioned as remotely as 1346. Despite their low specific gravity and resultant short range, their cheapness ensured continued use for centuries. Bronze shot are mentioned by Petrarch in one of his works written during or before 1344. According to Napoleon III the French used lead shot in 1345. Cast-iron balls did not appear until the 15th century, though crude wrought-iron specimens were in use before the 14th century ended. The introduction of cast-iron spheres did not result in the immediate abandonment of earlier types. Thus when certain guns were salved centuries later from the wreck of the British warship "Mary Rose," sunk in 1545, they were found to

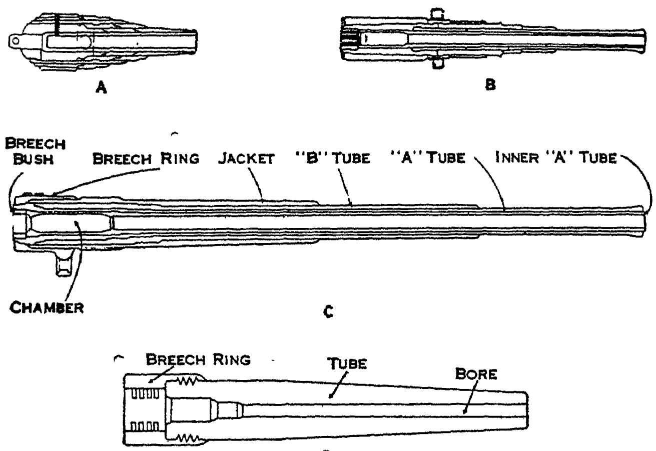

FIG. 5.—(A) MUZZLE-LOADING 12-IN. GUN OF 1864. (B) BREECH-LOADING 9.2-IN. GUN OF 1887 (SHRUNK HOOPS-STEEL). (C) 6-IN. STEEL GUN SHOWING CONSTRUCTION. (D) MONOBLOC TUBE

be loaded indiscriminately with balls of stone, wrought iron and cast iron. As late as 1578 the Tower of London housed 47,000 cannon balls of iron and 45,000 of stone. Given the same initial velocity, lead balls were the farthest ranging, followed by bronze, iron and stone, in that order.

Case Shot (Canister).—Early attempts to fire a volley of small shot from a single gun consisted of storing a number of projectiles (commonly flint pebbles) in a metal case (canister) and loading this into a gun of large calibre. Such a charge, reputedly developed as remotely as the early 15th century, could be murderously effective at a short distance. As the period advanced, canister loads of lead or iron balls of musket calibre and upward were developed for point-blank firing into massed troops. Longer ranging were grape shot, iron spheres from about 2 in. to 3½ in. in diameter and weighing from one to six pounds. Unlike case loads, which to all intents consisted simply of a tin can full of loose balls which started to fly helter-skelter almost upon leaving the muzzle, grape were packed in layers within a skeleton metal frame and held together for some distance before commencing to separate. Explosive shell are said to date to the late 14th century, although Hime states that the first record of their use "in large numbers and with good effect" was at the siege of Bergen-op-Zoom in 1588. They consisted originally of hollow spheres of hard-fired clay with very thick walls, each pierced with a fuze hole and filled with gunpowder. Unable to withstand much pressure, these were soon supplanted by hollow balls of iron. Into the fuze hole of each was driven a conical fuze, first of reed, then of wood, centrally bored to receive a train of compressed powder. In the beginning, the sole purpose of a fuze was ignition. But later, by a rough system of trial and error, it was, before insertion, cut long or short according to the estimated range at which the shell was desired to explode, then hammered into the cavity made to receive it. Shell containing a bursting charge and a number of small balls to be dispersed when the charge exploded (and thus to increase materially the number of flying missiles so produced) were developed as early as 1573. About 200 years later a new and much more efficient shell of this general type was developed by Sir Henry Shrapnel (*see* below).

Other artillery projectiles appearing during this era included carcasses (spheres filled with incendiary material to ignite flammable targets). To the same end were employed red-hot shot, heated in special furnaces and loaded very gingerly over wet clay wads, and incendiary rockets, though the latter saw no wide use during this period. For cutting the rigging of vessels, still other specialized projectiles—bar shot and chain shot—were developed.

SECOND PERIOD (c. 1713–1845)

This period marked the cessation for 100 years or more of the practice of casting cannon around a solid core to be withdrawn after the piece had cooled, and the adoption of a system whereby the tube was bored from a solid casting. (Core casting reappeared, with quite different techniques, as the period ended.) The newer practice is ascribed to Maritz, the Swiss previously mentioned,

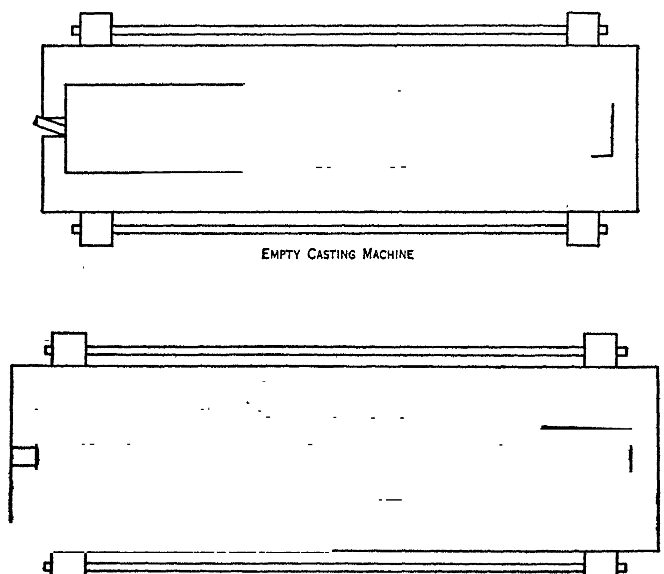

FIG. 7.—CENTRIFUGAL CASTING

who is said to have perfected it in 1713. Its outstanding advantage lay in the fact that by careful boring of the interior and turning of the exterior it was possible to produce a piece with walls of uniform thickness, a requirement not to be met under the earlier method because of the ever-present tendency of the interior clay core to move with respect to the outer one which enveloped it. So material was this improvement that the privy council of the Netherlands, by which Maritz was then employed, decreed in 1747 that his method would thereafter be followed exclusively. Furthermore, the process was declared secret, and all persons engaged in applying it were sworn to secrecy. However, it was obviously impossible long to prevent its disclosure, and by 1775 the British board of ordnance had followed the example of the Netherlands and was refusing to accept any gun not bored from a solid casting.

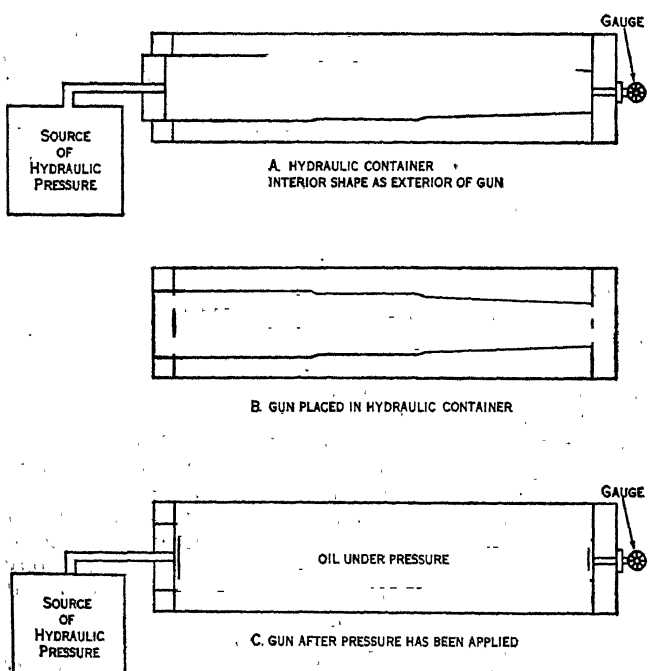

FIG. 6.—COLD WORKED PROCESS

(C-D) HYDROPNEUMATIC RECOIL SYSTEM WITH FLOATING PISTON SHOWING IN-BATTERY OR FIRING POSITION (C) AND END OF RECOIL (D). (E-F) HYDROPNEUMATIC RECOIL SYSTEM WITH FLUID IN DIRECT CONTACT WITH THE AIR, SHOWING IN-BATTERY OR FIRING POSITION (E) AND END OF RECOIL (F)

Further improvements in artillery during this period included new efforts toward: (1) reduction in the almost countless varieties of cannon and their attendant equipment; (2) standardization of types and of methods of manufacture; (3) reduction in windage (clearance between the projectile and the bore down which it travelled) and the introduction of a short, powerful naval gun of small windage—the carronade (*see* fig. 3); (4) interchangeability of parts; (5) greater use of cartridges (*i.e.*, charge and ball assembled into a single package and so loaded into the piece, instead of loose powder and shot, separately introduced); (6) the development of a horse artillery sufficiently mobile to manoeuvre with cavalry; (7) classification of land ordnance according to its special purpose, as for field, siege and coast defense; and (8) a truly scientific approach toward the study of the forces acting on a projectile while (*a*) within the gun bore (interior ballistics) and (*b*) while travelling from muzzle to target (exterior ballistics). For this last, Benjamin Robins, British mathematician, was responsible. Robins also strongly advocated the practice of rifling great guns, but another 100 years elapsed before his advice was followed.

Propellants of the Second Period.—During this period little change took place in the proportions of the ingredients of gunpowder. As early as 1670 these were recorded by Sir James Turner as follows: saltpetre, five parts; sulphur and charcoal, of each, one part (*i.e.*, 71.4%, 14.3% and 14.3%). By 1742 the figures had become six, one and one (75%, 12½% and 12½%), while by 1781 they were 75%, 15% and 10%, a ratio still practically unchanged at mid-20th century. Methods of manufacture, however, underwent tremendous improvement, and the cost of the finished product steadily declined.

Projectiles of the Second Period.—During this era the use of explosive shell in howitzers and cannon (they had theretofore seen service almost exclusively as short-range projectiles discharged from mortars) began to receive serious study. Some of the earliest trials of this expedient took place at the siege of Gibraltar in 1779, the conventional 5.5-in. mortar shell being fired from the standard British 24-pounder gun of the same bore. However, the fuzes performed erratically and the regulation heavy bursting charge shattered the casing into an average of eight fragments only, with little damage to the enemy. Shell containing a bursting charge and a parcel of balls to be dispersed upon explosion had long been in use (see *Projectiles of the First Period*, above). But they had never proved successful for reasons soon to be disclosed. Clearly there was need for a new type of projectile effective against troops in open order and beyond the range of case.

The problem was answered by the development of an improved shell which was originally known as spherical case but which, when adapted to elongated projectiles a half century later, became identified with the name of its inventor, Sir Henry Shrapnel. Conceived by him about 1784, it did not receive serious trial until 1803. Thereafter it underwent steady improvement but never achieved maximum efficiency until the appearance of a truly effective time fuze (1854) shortly after the period ended. Externally resembling the older spherical shell of the special type which housed an explosive plus a complement of small balls, it differed in that its reduced powder charge when exploding merely cracked open the outer casing and allowed the contained balls so released to continue their forward travel (with the velocity imparted by the original container) and to disperse gradually. By contrast, in the earlier type a much heavier disruptive charge scattered the balls in all directions at the instant of explosion. If that moment were not timed to occur exactly as the projectile passed over enemy ranks—impossible with the crude fuzes then existing—the shell was wasted. Shrapnel's device however developed a danger zone of considerable depth, with high antipersonnel effect when variations in fuze performance were not excessive.

Another noteworthy projectile appearing during this period was Sir William Congreve's rocket. Developed as a sort of auxiliary artillery, it bore the form of the conventional stick-guided sky-

rocket employed in pyrotechnic displays, but carried an explosive or incendiary head and was adaptable to use both by land and sea.

Coming into use shortly after 1800, and fired (on land) from light folding metal fixtures, easily portable, this rocket figured in a number of decisive battles between that date and the American Civil War (*e.g.*, Copenhagen 1807, Leipzig 1813, Bladensburg and Baltimore, 1814). During the 1840s a much more efficient type (stickless and self-rotating) was developed by William Hale of England, but the tremendous improvements in conventional forms of artillery which commenced almost immediately thereafter soon resulted in its almost complete eclipse, although it was still an article of issue in the British army as late as 1908. Thereafter it remained neglected until suddenly, in the early 1940s, it underwent an explosive reincarnation and became one of the most effective missiles of World War II.

In addition to the contributions of Shrapnel and Congreve to the improvement and diversification of projectiles for land use, the explosive shell, for centuries neglected by the maritime services, commenced early in the 19th century to receive increasing attention from naval authorities, chiefly through the efforts of the French Gen. Henri Joseph Paixhans. By the time the period ended, it was already threatening the dominance of the solid shot which had theretofore reigned supreme upon the seas.

THIRD PERIOD (1845–EARLY 1880s)

More progress in ordnance took place during this period than during the six centuries preceding. Outstanding were: (1) the perfection and general adoption of various systems of rifling for artillery (*see* fig. 10); and (2) as a corollary, the replacement of spherical projectiles by elongated types, cylindroogival in form and spin-stabilized by passage through rifled bores; (3) perfection and general adoption of various systems of breechloading (Great Britain, an exception, adopted then discarded breechloaders and did not resume their use until 1880); (4) the invention (independently) by two military men, the Belgian Capt. Paul Émil le Boulengé and the U.S. Capt., later Gen., Thomas J. Rodman (1860s), of the first really accurate devices for (*a*) measuring the velocities of missiles (the chronograph) and (*b*) estimating the pressures within gun tubes (the crusher gauge) which together helped to eliminate much of the guesswork previously involved in the design of guns and appropriate projectiles; (5) construction, commencing in the 1830s, of guns on the "built-up" principle as developed by the Frenchman M. Thiery (1834) and the Americans Benjamin Chambers (1849), Daniel Treadwell (1855), *et al.* These embodied tubes of cast or wrought iron (later of steel) surrounded by one or several reinforcing jackets (hoops) of wrought iron or steel, shrunken or screwed on. Thenceforward this was to represent the standard method of fabrication (*see* fig. 5, A). There followed a gradual displacement (beginning about 1856) of guns formerly produced as solid iron castings, by others exhibiting various combinations of forged iron, cast iron and finally steel, with or without jackets. By 1880 the all-steel gun was fast replacing all preexisting types.

An interesting throwback to the method of casting a gun barrel around a central core was developed soon after this period commenced by Captain Rodman. He employed a hollow core through which a stream of water was passed. By keeping the exterior of the completed casting warmed and so controlling its rate of cooling, he succeeded in causing the outer layers of the metal to shrink and thus compress the core (*i.e.*, the bore), securing by a different approach the same results as were attained by shrinking on hoops according to the built-up method. His system was ingenious and effective but came too late to see wide employment before metallurgical advances rendered it obsolete. (Compression of the bore of a cannon exerted upon it by outer layers of encircling metal helps it to resist internal pressures developed when a charge is fired, hence the various means devised to effect this.)

Alfred Krupp (Germany) was the first to produce a successful all-steel gun. Drilled out of a single block of cast metal, it was the marvel of its day. The first specimen to be shown at a world exposition, a modest six-pounder displayed at London in 1851, attracted universal attention. Within ten years Krupp was producing guns of 8-in. bore and larger, all from solid blocks of cast steel. However, after other makers had demonstrated the possibilities of all-steel guns on the built-up (hooped) system, he gradually adopted that method of fabrication also. (*See* fig. 5, B.)

The names of Sir William Armstrong and Sir Joseph Whitworth are closely associated with the development (1850s) of the wrought-iron, built-up, rifled cannon (*see* fig. 4), especially of the light field type, in both muzzle- and breech-loading varieties. Whitworth's was noteworthy in possessing a hexagonal bore. (*See* fig. 10.) The American Civil War of 1861–65 offered the first opportunity for a mass trial of rifled guns and, to a limited degree, of breechloaders as well. Even so, the vast majority of cannon figuring in the conflict were smooth-bore cast-iron (plus some brass) muzzle-loaders, although steps to modernize these by reaming out the original bore and driving into it a rifled tube of wrought iron or steel were commenced during this period and continued for a number of years thereafter. Wire-wound guns in which countless turns of fine wire coiled under tension replaced shrunken-on hoops as reinforcement for a relatively thin central tube had already been under development since about 1855 but were yet to receive the recognition later accorded them.

During this period another epochal change took place with the introduction and general adoption of iron and, later, steel plating as defensive armament on ships of war and in the gun emplacements of permanent land fortifications. The battle between U.S.S. "Monitor" and C.S.S. "Merrimac" ("Virginia") in Hampton Roads (March 1862) marked for all practical purposes the end of the unprotected wooden vessel. At the same time, increase in size and power of naval artillery necessitated gradual abandonment of the centuries-old method of controlling recoil by rope breechings only, or by breechings plus friction planes (*see* fig. 3), and the substitution of a carriage fitted with vertical iron friction plates moving between other plates attached to a slide positioned between carriage and deck, and automatically compressed as required to develop the amount of friction necessary to absorb recoil.

Even this material improvement soon proved inadequate and

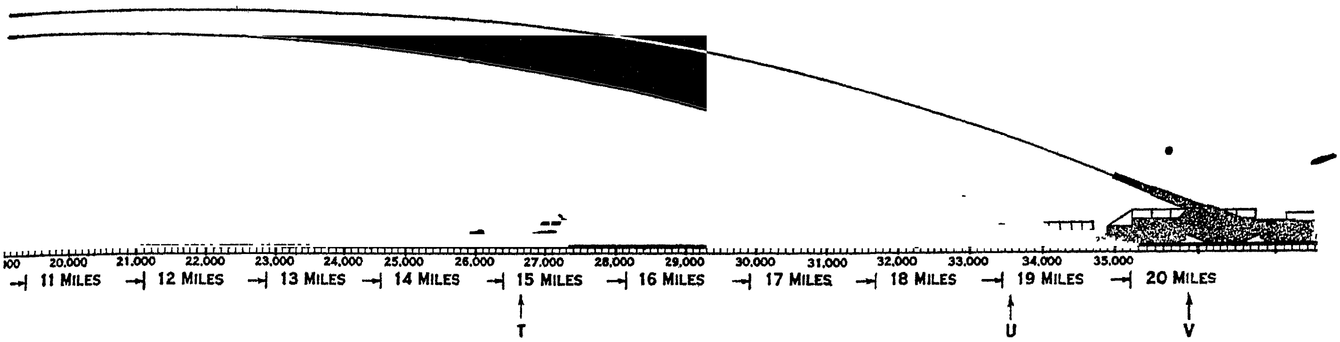
UNITED STATES COAST DEFENCE ORDNANCE

1. A 14-in. mobile coast defence rifle mounted on a railway carriage. The big gun has an effective range of 27 miles
2. A 14-in. rifle on railway mount having an effective range of more than 27 miles
3. A 12-in. railway mortar going into firing position at Fort Monroe, Virginia
4. Firing 12-in. mortars at Fort Monroe, Virginia
5. Midshipmen of the U.S.S. "Nevada" at the 5-in. guns used for torpedo boat defence
6. Coast Guardsmen operating a 3-in. gun on the U.S. Coast Guard cruising cutter "Modoc"



THE BRITISH PIECES OF ORDNANCE USED IN WORLD WAR I
(Mark IV), (M) 6-in. 26-cwt. howitzer, (N) 15-in. howitzer, (O) 8-in. (Mark VII) howitzer, (P) 9.2-in. (Mark II) howitzer, (Q) 60-pounder (Mark I), (R) 12-in. (Mark V) howitzer, (S) 6-in. (Mark XIX) gun, (T) 9.2-in. (Mark X) gun, (U) 12-in. gun (Mark IX), (V) 14-in. gun (Mark III)

was supplanted both on sea and land by systems in which cylinders attached to the carriage contained air, liquid, spiral springs or combinations of these to be compressed during recoil by a piston attached to the gun (*see* fig. 8). Anyone was capable of neutralizing the full energy of recoil and, when this was dissipated, of returning the piece to battery (firing position). Such systems continued in use to and through World War II.

Propellants of the Third Period.—Black gunpowder remained king despite a brief threat from guncotton as developed by Austria in the 1850s, both as a propellant and as an explosive charge for shell. It proved dangerously unstable, however, and after a series of disastrous explosions at manufacturing plants was discarded. As a result of the efforts of Rodman and others, who developed grains in new sizes and shapes, some perforated, and so learned how to control in large measure its rate of burning, black gunpowder became much more versatile than ever before.

Projectiles of the Third Period.—With the general adoption of rifling, the advantages of elongated projectiles (which fly farther and straighter when discharged from a rifled tube than do spheres of equal weight) could now be exploited, and these were produced in myriad types. The long-used spherical case gave way to the elongated form thereafter called shrapnel for its inventor, and employed in increasing quantities to and through World War I, after which it became obsolete, being entirely replaced by high-explosive shell. Nevertheless, as much later as the Korean war of the 1950s, injuries from shell fragments were still erroneously being designated as shrapnel wounds.

As the period progressed, solid shot gave way entirely, except for target purposes, to armour-piercing shell and common shell, the former with a small, the latter with a large, cavity for the explosive charge. As the period ended these, with shrapnel and canister, armed with one of the many newly developed and greatly improved types of fuzes, time or instantaneous, base-detonating or point-detonating, had become pretty well standardized.

The use of fixed ammunition with projectile and propellant combined in a single brass case became the general practice for field artillery of light and medium calibres, supplanting the old method of loading powder in cartridge bags behind a separate projectile. In moderately heavy calibres the projectile was loaded first, followed by the case containing the powder. This was known as separate loading. For the heaviest guns, bag loading, with the naked projectile followed by a number of cylindrical powder-filled bags, continued to be accepted procedure.

FOURTH PERIOD (1880–1940)

This was the era of the all-steel gun (*see* fig. 5, C), smokeless powder and mechanically controlled recoil. Great changes were witnessed but they were relatively less epochal than those recorded during the period just ended. There were comparatively few innovations; in general, ordnance matériel merely became "bigger and better." Cast steel was generally replaced by forgings for gun tubes and reinforcing hoops, though some "monobloc" guns (of a steel tube forged or cast in one piece plus a screwed-on breech jacket) were being produced (*see* fig. 5, D). The addition of small amounts of other metals (nickel, molybdenum, etc.) to batches of steel while still in the crucible, combined with improved methods of casting, forging and heat treating, produced alloys with highly improved physical characteristics and permitted the construction of guns which would withstand more powerful charges and achieve correspondingly greater ranges than had their predecessors. By World War I, the conventional field gun of about 3-in. bore was reaching out to around 9,700 yd., the 6-in. piece to about 17,700 yd. (By the time of World War II, figures for comparable pieces were 14,000 and 25,000 yd., respectively.) Following World War I a new procedure was introduced for producing gun tubes by a process of centrifugal casting (*see* fig. 7), then bore-hardening them by "autofrettage" (compression within a closed container by the action of water introduced under terrific pressure; *see* fig. 6). These methods were increasing in popularity as World War II approached. Smokeless powder as a propellant for both small arms and cannon projectiles appeared in 1886 and was in general use for military purposes by 1900. Lengths of gun barrels increased from the optimum of 18 calibres suggested by the U.S. ordnance manual of 1861, to 50 calibres and more. Muzzle velocities up to 3,000 ft. were attained, though in general these did not exceed 2,500 foot seconds. An exception was afforded by the German guns bombarding Paris in 1918. With a bore of 8.26 in., and a barrel more than 100 ft. long, these launched their projectiles to distances up to 75 mi. with muzzle velocities of 5,500 foot seconds and breech pressures ranging to 70,000 lb. per square inch, 30,000 to 40,000 lb. above standard practice. Another ordnance achievement of that war was the German "Big Bertha" 42-cm. (16½ in.) mortar-howitzer, specimens of which destroyed the forts at Liège and Namur, the explosion of a single shell producing destructive effects previously unimagined. For their part, the Allies perfected and employed with much success on the western front railway artillery in calibres up to 16 in., while, by reason of the long period of stabilized warfare on that front, both sides developed and used extensively trench mortars in calibres of 3 in. to 240 mm. (9.45 in.).

In the years that followed, the rapid expansion of air power caused marked changes in the ordnance picture. It became necessary to invent and produce devices to detect oncoming planes at considerable distances, to track them when once located and to compute automatically and feed electrically to gun batteries the necessary firing data, including height, speed and slant range of the target. To reach out for the constantly higher and faster flying planes of the enemy, quick-firing anti-aircraft guns of calibres from 37 mm. to 120 mm. (1½ in. to 4.7 in.) with vertical ranges up to 56,000 ft. were designed and fabricated. The rapid evolution of the tank, which during World War I had been little more than a mechanical curiosity, called for special cannon for installation on these vehicles and on motor gun carriages, also of others for anti-tank use, not to speak of protective armour for the behemoths that were already under development. Aircraft bombs of increasing size and power were produced, and by the same token the usefulness of heavy guns in fixed installations such as coastal defenses decreased to the vanishing point.

Propellants of the Fourth Period.—Black gunpowder ceased to be used as a propellant, though small quantities were employed

as igniters in the now standard smokeless loadings and to expel the contained balls from shrapnel shell. Coating of individual grains with deterrent compositions (to retard the rate of burning), and the production of grains in the sizes and shapes found by experiment to be most efficient for a gun of a given type, permitted a considerable degree of control over speed of burning and, as a consequence, over chamber pressure and muzzle velocity.

Projectiles of the Fourth Period.—During the first few years of the period explosive charges for projectiles consisted chiefly of picric acid under various names (lyddite, melinite, shimose, etc.) and during the latter years of trinitrotoluene (T.N.T.), but by World War I dozens of satisfactory explosives were available, and of course even more as World War II approached, although methods for mass producing more than a few of these at reasonable cost were yet to be developed. Time fuzes which had originally incorporated a powder train to burn for a predetermined number of seconds were giving way to others mechanically actuated and more efficient in performance. New, speedier and cheaper methods of producing ammunition components were evolving as the 1930s ended, and substitutes for metals difficult of procurement in time of war were being exploited. Appropriations by major powers for ordnance matériel, fallen to near-zero in the period following World War I, were being voted in amounts considered fantastic, but which, by comparison with those of the war years to follow, were little more than niggardly.

FIFTH PERIOD: THE ATOMIC-ELECTRONIC ERA

The period after 1940 saw most of the nations of the world engulfed in World War II (1939–45), followed by the so-called "cold war," the fighting in Korea in the early 1950s and a prolonged struggle in Indochina. During the decade of the 1940s the supply of weapons to military forces became for a time the primary business of mankind. Standard types of small arms and artillery pieces were produced in great quantities, and a host of new and improved devices was brought forth. Rockets, guided missiles, recoilless weapons, fire bombs, giant tanks—in all these fields there were striking new developments. Most awe-inspiring of all was the development of the atomic bomb, followed by the vastly more potent hydrogen bomb in the early 1950s.

Research and Development.—During the Napoleonic era it was often said that victory in war belonged to the side with the big battalions. By the time of World War I (1914–18), when huge quantities of guns and ammunition were needed, this maxim was revised to say that victory belonged to the side with the big factories. During World War II (1939–45), when the full force of scientific knowledge was applied to the development of weapons, it was commonly said that victory belonged to the side with the big laboratories. As the 20th century passed its mid-point, intensive application of science to war purposes had resulted in the development of such a host of weapon types that a mere listing of the new devices would fill a large volume.

All major powers in World War II attempted with greater or less success to mobilize their scientific resources for the development of new and improved ordnance. The term "research and development" rose to a position of prominence equal to the older military terms such as "supply," "strategy" and "intelligence." Exchange of scientific information regarding new weapons among allied nations became as important as that concerning the strength and disposition of forces in the field. In Germany, Hitler dramatized the work of his military research scientists and attempted to raise the morale of his people and strike terror in the hearts of his enemies by repeatedly promising that new secret weapons would soon appear in the hands of German forces to turn the tide of battle.

Research and development on new military weapons are usually long and arduous. Ideas seldom if ever spring full-blown from the mind of an imaginative inventor. Like their counterparts in civilian life, they are usually the products of years of patient study and experiment in laboratories and proving grounds. Often the motivating force that starts the train of research is the appearance of a new enemy weapon which must be countered. More often new devices appear as the result of years of effort to achieve greater fire power, increased mobility or better protection against weapons long known to be in possession of the enemy. Ordnance research includes both basic research—the discovery of new scientific knowledge—and applied or technical research, which is concerned with the application of existing knowledge to a specific use. It requires laboratories and firing ranges equipped with a bewildering array of ingenious weighing and measuring instruments, high-speed cameras, wind tunnels and electronic calculating machines. Once a working model of a new weapon is designed it must be improved or developed as its deficiencies become apparent through severe proving-ground tests. For long-range weapons such tests are conducted on tracts of uninhabited land, some of which cover thousands of square miles. Finally, ordnance research must extend also into the realm of production, for a weapon that cannot readily be produced in quantity with available raw materials has limited military value.

Economy in Manufacture.—In the manufacture of military arms and equipment every major power is forced to practise economy in the use of materials, machine tools and manpower. Efforts are made to devise the most efficient manufacturing techniques, for the demands of the military forces are so great that no nation can afford to waste its productive power. This is particularly true in time of war, when the nation may be suddenly cut off from its normal overseas sources of supply and when a large proportion of its manpower must serve in the armed forces.

Among the major powers engaged in World War II, perhaps the most critical metal shortage, as far as arms manufacture was concerned, was in copper. For many years the standard material for cartridge cases around the world had been brass (an alloy of copper and zinc), for it not only possessed the required elasticity and ability to resist corrosion but also was adaptable to mass production. The Germans succeeded in making steel cartridge cases, but in the United States the development of steel cases was less successful. In the late 1940s the U.S. army continued to study the matter and gave close attention to the shaping of steel by the

cold extrusion method used by the Germans rather than by the traditional practice of punch and draw. Another step to conserve copper was the substitution of copper-clad steel for gilding metal (90% copper, 10% zinc) in small arms bullet jackets.

To conserve aluminum, for which there was great demand by the aircraft industry, many changes were made in ordnance matériel. Ammunition chests were constructed of steel instead of aluminum; handles of inspection gauges and other items were converted to plastic or wood; plastic took the place of aluminum in mortar fuzes. Application of the die-casting process to manufacture of aluminum parts yielded substantial savings of aluminum, for it made possible the use of secondary scrap metal and saved both labour and machine time. The design of weapons to speed production, reduce cost and save labour and machine time is strikingly illustrated by the U.S. army's submachine gun M3, made largely of steel stampings instead of finely machined parts and costing only one-third as much as the pre-1940 model.

One of the most significant developments of the period following World War II was the steady growth in the use of powder metallurgy. In this process the metal is reduced to powder (sintered) and is then pressed into the desired shape. Both the United States and Germany used sintered-iron rotating bands for artillery shell during the war and produced millions of small arms ammunition components from iron and steel powders and from tungsten carbide.

Small Arms.—The basic infantry weapon of the U.S. army in World War II and in Korea (1950–53) was the calibre .30 rifle M–1, popularly known as the Garand rifle after its inventor, John C. Garand, an engineer at Springfield (Mass.) armoury. It is a rugged, comparatively light-weight, semiautomatic, gas-operated weapon. The British army used the calibre .303 bolt-action Enfield rifle in World War II, the Germans a 7.92-mm. (.312-in.) bolt-action Mauser rifle and several models of 7.92-mm. semiautomatic rifles. In 1951 the U.S. army announced that it had developed a calibre .30 rifle weighing less than the Garand, capable of semiautomatic or full automatic fire and using a new lightweight cartridge. For any such weapon, it should be noted, only brief bursts of automatic fire are possible because of the small magazine. The British army meanwhile had developed a calibre .280 rifle that rivalled in effectiveness the new U.S. weapon. The standard shoulder arm of the Soviet army was the 7.62-mm. (calibre .30) bolt-action carbine that would be classed as a rifle in the United States. For service and rear-area troops the U.S. army adopted the semiautomatic calibre .30 carbine during World War II to replace the pistol, and later introduced a modified version capable of automatic fire. For the same purpose the German army used a 9-mm. machine pistol and a 7.92-mm. carbine. The U.S. Browning automatic rifle (B.A.R.) is a fully automatic calibre .30 weapon that weighs, with magazine and bipod, less than 20 lb. Its German counterpart was the 7.92-mm. automatic rifle.

Both rifles and carbines may be equipped with bayonets for hand-to-hand combat and with grenade launchers to give the foot soldier added striking power. Anti-tank and antipersonnel rifle grenades were used by all major powers in World War II. For use against tanks, a shaped charge grenade (*see* below) is effective at close range. White phosphorous rifle grenades may be used for setting up a smoke screen or for their physiological effect, and smoke grenades of various colours are employed for signalling.

The flame thrower is a fearsome weapon that employs compressed gas to project a stream of burning fuel into caves or pillboxes to burn, blind or suffocate the enemy. The portable unit is carried and fired by one man, usually under protection by other soldiers who cover the enemy with small-arms fire. The flame thrower is fired in short bursts of two or three seconds each to a range of about 100 ft. As early as 1942 the British mounted heavy flame throwers with longer range and greater fuel capacity on Churchill tanks.

In World War II the famous calibre .45 submachine gun known as the Tommy gun was supplanted by a cheap, mass-production gun (M3) commonly called the grease gun because of its similarity in appearance to the tool used to lubricate automobiles. The U.S. counterpart of the British Sten and German Schmeisser, it weighs only eight pounds and can fire at a rate of about 400 rounds per minute. Its barrel and bolt assembly can readily be replaced to permit firing the 9-mm. pistol cartridge common in Europe. The British army uses the Bren calibre .303 light machine gun as well as other types such as the Lewis, Vickers and Hotchkiss. The Soviet army is supplied with a 7.62-mm. submachine gun under the name of machine pistol. Machine guns of calibre .30 and .50 (both air-cooled and water-cooled) are used by ground troops to provide a heavy volume of fire at comparatively short range. The calibre .50 water-cooled gun of the U.S. army weighs about 100 lb., has a rapid rate of fire and is often used as an anti-aircraft weapon. The standard machine gun of the German army in World War II was the 7.92-mm. M.G.34 that could be used for anti-aircraft fire as well as against ground targets. The Soviet army employs three air-cooled machine guns, a light 7.62-mm. company machine gun, a medium 7.62-mm. Goryunov (named for its designer) and a heavy 12.7-mm. (calibre .50) that may be detached from its wheeled mount and set up for anti-aircraft fire.

Aircraft Armament.—This is a special field with distinctive requirements stemming from the fact that weight and space factors are of great importance in combat planes. The extremes of temperature encountered in high-altitude flight must also be considered in designing aircraft weapons. As the high speed at which planes travel means that the time gun sights are on the target is often only a fraction of a second, automatic weapons with high cyclic rates are used to increase the probability of scoring a hit. The weapon most used on British and U.S. planes is the air-cooled calibre .50 aircraft machine gun. Powerful enough to cripple an opposing plane if it strikes a vital spot, and effective against certain ground and naval targets as well, it has a cyclic rate of more than 1,200 rounds per minute. A bomber can carry more than a dozen such weapons plus a large supply of ammunition (including incendiary and tracer rounds) to give it all-round protection. Fixed aircraft guns are mounted in a fixed position, as in the wings or nose; they are aimed by manoeuvring the plane and fired by remote control. Flexible guns are mounted so they may be swung on a pivot to aim at their targets.

The 20-mm. automatic aircraft cannon used by the British and U.S. air forces in World War II and favoured by the U.S. navy in the postwar years weighs only a little more than 100 lb. and fires at a rate of 800 shots per minute. Both Germany and Japan made use of similar 20-mm. weapons. The 37-mm. aircraft gun weighs much more and has a correspondingly lower rate of fire. The largest gun used in aircraft during World War II was the 75-mm. aircraft cannon, but the U.S. army also developed a 105-mm. aircraft gun. Rocket launchers (*see* below) are mounted on planes for both air-to-air and air-to-ground attack.
